MOST text-books of elementary zoology contain an account of the circulation of the frog. These accounts, which are based largely on the views of Brücke[1] and Sabatier[2], differ in minor details, but agree that the frog's heart, though possessing only a single ventricle, functions, nevertheless, so that the so-called arterial blood, returning by the pulmonary veins, is mixed only slightly with the venous blood. The mixed blood is sent through the systemic arches to the hinder part of the body. Meanwhile the head region is supplied through the carotid vessels with pure arterial blood, while the greater part of the venous blood is sent through the pulmo-cutaneous vessels to the lungs and skin.

This hypothesis, based on somewhat slender experimental evidence, proved very satisfactory, no doubt, to the nineteenth-century comparative anatomists. Then it seemed natural to seriate the incomplete double circulation of the frog, as an example of the Amphibia, between the single circulation of the fish on one hand and the double circulations of certain reptiles, birds and mammals on the other. Since the time of Brücke, however, many facts have been discovered. For example, the incompletely divided heart of *Lepidosiren* has been described[3]; again, the results of palæontological investigation have shown that, so far as their skeletal elements are concerned, the modern Amphibia have departed widely from the structure exhibited by the earliest members of that group[4]. In addition, there have been described[5,6] certain abnormal hearts of individual frogs in which the circulation could not possibly take place as the Brücke – Sabatier hypothesis requires; the fact that such frogs were apparently capable of leading a normal existence shows that the supposed selective distribution of the blood is, in fact, unnecessary.

In more recent years, Ozorio de Almeida[7] and Noble[8] claim to have demonstrated by experimental methods that in certain Amphibia in which the interauricular septum is complete and a spiral valve present in the conus, the arterial and venous bloods mix but little. However, Vandervael[9], who was the first to place an illuminant under the heart and observe the passage through it of Indian ink particles by means of transmitted light, found that very considerable mixing does take place. This author also directed attention to certain physiological considerations, notably the extensive cutaneous respiration of the frog, and concluded that a mixing process is much more likely to be in keeping with the frog's mode of life; for when it is submerged the skin will be the only source of oxygen supply (apart from any stored in the lungs). He suggests that when lung breathing is used, it will supplement the oxygen content of the blood obtained from cutaneous and bucco-pharyngeal respiration, and that, by mixing, this increase will be distributed to all parts of the body.

Recently[10], Vandervael's experiments have been repeated using methods which obviate both the possibility of the injection increasing the cardiac intake in such a way as to invalidate the results, and also that of affecting the heart by heat derived from the illuminant. The results obtained confirm Vandervael's observations. By the methods used it can clearly be seen that (*a*) the spiral valve of the conus does not direct the first blood to leave the ventricle into the pulmo-cutaneous vessels, as the old hypothesis requires; (*b*) that the blood commences to move and ceases movement in the carotid, systemic and pulmo-cutaneous arches simultaneously and not consecutively; (*c*) when Indian ink particles are introduced into the blood-stream by way of the pulmonary vein, they are distributed to carotid, systemic and pulmo-cutaneous trunks and not to the first two of these only; and (*d*) when introduced through one of the anterior venæ cavæ, or a tributary of these, Indian ink is not excluded from the carotid circulation.

This work has now been extended[11] by the introduction into the blood-stream of the radio-opaque medium 'thorotrast'; its subsequent movements being traced by serial radiographs made at intervals of a few seconds. This has overcome the difficulty of making direct observations with transmitted light and has provided permanent records of the distribution of the injection medium when injected both through the pulmonary vein and vena cava routes. These radiographs give no support whatever to any non-mixing hypothesis, and indicate strongly that considerable mixing does, in fact, take place.

We are thus faced with the situation that, on the experimental evidence before us, the non-mixing hypothesis is not proved; it is also at variance with the evidence derived from the physiological study of the frog's heart and the study of abnormalities. Palæontology, so far as it can be introduced into the present argument, points strongly to the fact that it is undesirable to attempt to place the modern Amphibia anywhere near the main line of vertebrate evolution. In the present state of our knowledge, it seems best to regard the frog's heart, with its adaptations for receiving its oxygen and food supplies from the blood passing through it and not, as in other vertebrates, by way of a coronary supply, as being specially adapted to an animal in which a high proportion of the respiratory exchange is cutaneous.

A Mistaken Symbiont of *Oliarus cuspidatus*

Buchner[1] mentions somewhere in his work, unfortunately not available here, that in the absence of general knowledge of symbiosis, spermatozoa have been recorded in the literature when they were really bacteria. At least in one instance enthusiasm has led to a mistake in the opposite direction, for spermatozoa have been illustrated as bacteria. *Oliarus cuspidatus* is a Fulgorid insect which is supposed to contain as many as five tumours, each with a specific symbiont of its own; this record being the highest claimed so far. It is a rare insect in Germany, where even Buchner was unable to procure any specimen for his own investigation. Šulc[2] found it near Brno in Czechoslovakia, and our knowledge of symbiosis in this insect is entirely due to him.

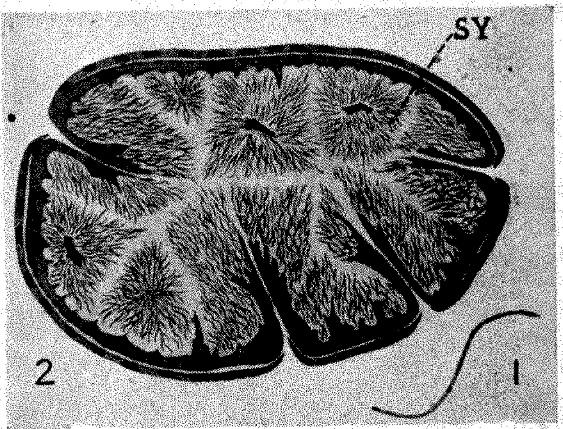

Fig. 1. Symbiotic bacterium of *O. cuspidatus* according to Šulc, who has idealized it as such. Reduced to ⅔

Fig. 2. Section of tumour with symbiotic bacteria *SY*, in *O. cuspidatus*, according to Šulc. This is a male gonad, *SY* being spermatozoa. Reduced to ⅔

I spent some four months in Brno, where Prof. Šulc kindly procured for me a few specimens of *O. cuspidatus*. In the following year I moved to Prague, where Dr. Stepanek, of the National Museum of Natural History, kindly directed me to a locality from which I obtained a few living specimens of this insect. Neither at Brno nor at Prague could I confirm the existence of bacteria illustrated by Šulc[2] in his Fig. 21, which I have copied (see Fig. 1). The micro-organism is so long that anyone searching for it should have easily confirmed the previous record. The tumour containing these long bacteria has been named by Šulc "interfollicular mycetome" and illustrated in his Fig. 20, showing the symbionts as *Sy*; his illustration has been copied (see Fig. 2). Strangely enough, I could not even find this tumour in *O. cuspidatus*. Buchner[3], and more recently H. J. Müller[4], have studied Fulgoridæ, but neither their studies nor those of Šulc himself upon other Fulgorid insects refer to an interfollicular tumour, *O. cuspidatus* being the only exception recorded in the literature.

After much labour and disappointment I have come to the conclusion that Šulc has unwittingly illustrated the testis of a male insect, and naturally mistaken the spermatozoa for bacteria. In the male gonad the spermatozoa lie relatively scattered and are radially arranged; both these features are clearly expressed in Fig. 2. On the contrary, a section of an insect tumour shows the tissue cells thickly seeded with bacteria which grow in all possible directions. Such an infected cell of the Fulgorid insect, *Fulgora europœa*, has been illustrated by Buchner[3] in his Fig. 6, Plate VIII, which is in harmony with that of another insect, *Cicadella viridis*, as illustrated also by Buchner in Fig. 18, p. 137.

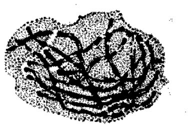

Fig. 3. Symbiotic bacteria of *Tricentrus assamensis* showing interplasmatic infection; magnification 12 × 60; camera lucida drawing

To my knowledge a bacterium in symbiosis with insects which excels all others in length and thickness, when these qualities are considered jointly, is to be found in an Indian Membracid, *Tricentrus assamensis*. A smear from this insect shows pieces of protoplasm with interplasmatic infection (Fig. 3). The bacteria never show any approach to a radial arrangement, typical of spermatozoa as seen in Fig. 2. The bacteria, on the contrary, grow in more than one direction, a feature well brought out in Buchner's illustrations mentioned above. On account of the large size of the bacteria found in *T. assamensis*, it has made possible the correct interpretation of more than one mysterious problem in the literature on symbiosis. Šulc's illustration (Fig. 2) is a genuine representation of an insect testis, only misinterpreted as a tumour; but his Fig. 1 here has been idealized as a bacterium to suit a preconceived theory. The wavy shape of the objects in Fig. 2 further suggests their being spermatozoa.

Helminth Parasites of Limpets

During investigations of the helminth parasites of the British limpets *Patella vulgata*, *P. intermedia* and *P. depressa*[1,2] in relation to a possible bearing of parasitism on mortality and sex-proportions[3], three larval trematodes (*Cercaria patellæ* Lebour[4], an unidentified *Xiphidiocercaria* and an unidentified tailless cercaria) and one larval cestode have been found (see table).

Host species	No. of specimens examined	Number of specimens found infested with			
		C. patellæ	*Xiphidiocercaria*	Tailless cercaria*	Cestode
P. vulgata	3631	121 (3%)	7 (0·2%)	22 (4%)	4 (0·1%)
P. intermedia	595	49 (8%)	10 (1·7%)	26 (19%)	1 (0·2%)
P. depressa	1417	278 (20%)	nil	12 (5%)	nil

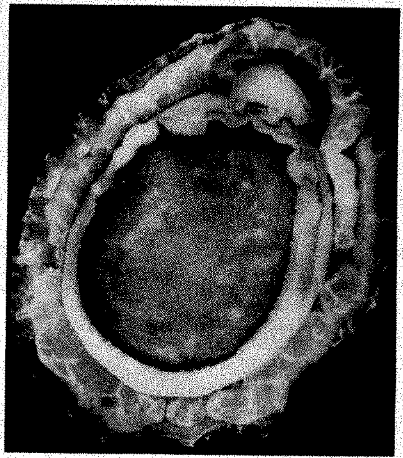
* Only 957 specimens (all species) were examined for this parasite.

C. patellæ is the commonest, is most abundant in autumn and is of special interest as a source of living cercariæ for class-work. It has been found on the west coast of Britain in several localities between Cornwall and Millport, and at Aberdeen, Cullercoats and Plymouth, being most abundant in *P. depressa* at Port St. Mary, Isle of Man, and at Trevone, north Cornwall.

Each of the three trematodes occurs independently in the digestive gland, the cestode being encysted on the surface of the visceral mass. The tailless cercaria is visible only under the microscope in smears of digestive gland tissue, but infestations of each of the other three parasites can usually be seen on lifting the foot forward from the visceral mass.

C. patellæ is commonest in *P. depressa*, but since in all three species it is more common in populations inhabiting rock pools than in those living in exposed situations, the apparent preference for *P. depressa* may be because this species occurs in pools or at low water, whereas the other species frequent 'dry' habitats.

Most limpets infested with *C. patellæ* are in the larger size (age) groups. The infestation in *P. depressa* at Port St. Mary is 10 per cent in specimens less than 35 mm. in length, increasing to 100 per cent in those more than 65 mm. (cf. Rothschild[5,6]). One of the more obvious effects of parasitism is castration of the host, infested limpets rarely having gonads normal in size; only 20 per cent, about two thirds of which were female, were found with identifiable sex products. The effects of infestation on the host organs have been discussed by Rees[7]. There is no apparent difference in vitality between infested and uninfested limpets, although in the final stages of infestation only a very small portion of the digestive gland remains unaffected. Infestation may, however, have an important effect on mortality and sex ratio in the larger individuals of all three species.



Patella depressa (Trevone) showing mantle veinlets filled with cercariæ ready for escape. (Natural size)

The sporocysts of the *Xiphidiocercaria* are restricted to a limited portion of the digestive gland or, rarely, kidney. No sporocysts of the tailless cercaria have been observed.

C. patellæ has been found to escape from the host by means of the veinlets in the mantle skirt which, filled with cercariæ, show white and opaque against the translucent mantle (Fig. 1). It is suggested that migration of cercariæ within the hæmocœle, and subsequent escape from the mantle, may be a common occurrence in other molluscs infested with larval trematodes.

The number of cercariæ given off by the limpet *in vitro* is greatest just after immersion in water. Up to 330 cercariæ may emerge in the first hour, the rate of escape then steadily falling and finally ceasing after about thirty hours immersion (compare Cort[8]). Under natural conditions there is probably a rhythm imposed by tidal fluctuations, the cercariæ only escaping when the host is covered by the tide.

The final host of *C. patellæ* is as yet unknown, although Nicoll[4] suggested that it may be a bird. It is possible that moribund or recently dead sea-birds, perhaps fouled with oil, may provide material, for which I should be grateful.

A full account of the work will be published later.

SEA WAVES

By P. J. H. UNNA

Secondary Waves and Tidal Streams

THE following symbols are used :

D = depth
L = length of primary.
H = height of primary.
$S = H/L$ = steepness of primary.
V = speed of primary.
L', etc., relate to secondary waves on crest of primary.
L'', etc., relate to secondary waves in trough of primary.
L'_0, etc., relate to secondary waves at mid-height of primary (at orbit centre level).
a = run.
v_a = water speed at crest.
a_s, v_{as}, relate to surface water.
a_0, v_0, relate to water at bottom.
L_0, H_0, S_0, V_0, relate to deep water.
Units—pounds, feet, seconds, except where otherwise stated.

Expressions showing the changes which take place in secondary waves, according to their momentary positions on a trochoidal deep-water primary, have already been explained[1]. The general forms, which cover all values of D/L for the primary, are :

$$\begin{array}{l|l} L'/L'_0 = 1 - \pi S.\coth\dfrac{2\pi D}{L} & L''/L'_0 = 1 + \pi S.\coth\dfrac{2\pi D}{L} \\ H'/H'_0 = L'_0/L' & H''/H'_0 = L'_0/L'' \\ S'/S'_0 = (L'_0/L')^2 & S''/S'_0 = (L'_0/L'')^2 \end{array}$$

For a deep-water primary these reduce to $L'/L'_0 = 1 - \pi S$, etc., as previously given ; and for a 'long' primary, $L'/L'_0 = 1 - \frac{1}{2}H/D$, etc.

The expressions are only strictly correct when L'_0/L is small.

The general expressions may be relevant in regard to the question of the depth of water in which waves of given height will start to break[1], but that is a subject on which many other considerations arise, and so it will not be discussed now. But the forms which apply when the primary is a 'long' wave show how tidal streams can, in certain circumstances, affect the state of the sea in a way which was not noted when waves and tidal streams were previously discussed in *Nature*[2].

Effect of Tidal Streams

The tidal wave will be taken as the primary, and the principal wind-formed waves as secondaries, and so H becomes range of tide. But whether the secondaries happen to be close inshore, or in mid-channel, D must be taken as the average depth throughout the width of the channel. Similarly, with an open coast, it would have to be taken as the average depth for many miles out.

The expressions to be used are naturally those for a 'long' primary, and they will only be strictly applicable where tide and half tide prevail ; while they will not have much effect unless the sea is fairly shoal, and the range is large. But they may have considerable consequence in places, for with a range of 16 ft., and soundings averaging 25 fm., the steepness of the sea should theoretically vary by 16 per cent as between high and low water, S'/S'_0 and S''/S'_0 working out at 1·08 and 0·92.

The conditions here are different from those previously considered in *Nature*[2]. The former note on effect of tidal stream stated that "Change in direction or strength of stream will not change the steepness of the waves if they are travelling through an area of uniform tidal strength—uniform maximum strength". It was intended to infer that the same strength of stream would be encountered at any given moment throughout the area, and that any change in stream would take place simultaneously, also throughout the area ; and with that proviso the statement was perfectly correct. But a long-term view must now be taken, covering half the tidal period, so that at any given moment both stream and change in stream may differ as between one position and another. Then the waves crowd up and shorten, and the energy crowds up and makes them higher when the water crowds up on the flood, with the reverse during the ebb. The resulting theoretical difference in steepness, as between high and low water, merely depends on the geometrical properties of the elliptic trochoid (tracing curve an ellipse) appropriate to the values of L, H, D.

But the expressions must not be applied too literally, for that would imply that the tidal wave behaves as it ought to do ; whereas if it did so, full strength of stream would be given by $\frac{1}{2}H\sqrt{g/D}$, equivalent to $1{\cdot}7\ H/\sqrt{D}$ knots, which is not the case. The probability is that tidal movement is greatly affected by irregularities in coast line and soundings, and also by reflexion of the tidal wave. But nevertheless, the argument that where the water crowds up, the waves, and their energy which is carried by the water, must do the same, holds good ; and that will apply both for tide and half tide, and also in estuaries, where the stream turns at high and low water by the shore. So where an estuary has a large H/D, it may be anticipated that the sea will be heavier at high than at low water ; and perhaps this is the reason why, in an onshore wind, the water so often seems to quieten down towards low water, even before the weather-going stream has ceased to run. In this connexion the following figures are relevant :

With tide and half tide :

H/D	0·1	0·3	0·5	0·7
S'/S'_0	1·1	1·4	1·8	2·4
S''/S'_0	0·9	0·75	0·65	0·55

In the Bristol Channel

	H/D at mean springs
Lundy	0·12
Ilfracombe—Mumbles	0·25
Foreland—Porthcawl	0·35
Watchet—Barry	0·6
Flatholm	0·7

This may account for the Bristol Channel pilots' allegation, previously mentioned in *Nature*[2], that the heaviest seas off the Foreland occur at high water. At neaps, and in other estuaries with smaller range, the effect would naturally be less. In any event, the above figures can only give quite a rough idea of what should happen, for, especially in an estuary, the waves have plenty of time, during half the tidal period, to run between positions with greatly differing values of H/D, and that complicates things a lot. For example, L'_0 would differ as well as H/D.

Lastly, it is worth noting one curious consequence. Where two tidal waves interfere, the change in the state of the sea, as above explained, should be greatest where the streams are weak, and least at the nodal position, where they are strong.

Shore Breakers

The essential condition for pure breaking is that v_{as} should just exceed V. That happens in deep water when $S = 0{\cdot}13$, a far greater steepness than waves of substantial length can then attain, unless they meet a weather-going stream[3]. When they are so steep, they are distorted from trochoidal profile, the crests being further steepened into sharp-edged ridges[4]. An extra steep crest of this sort can only be piled up if v_{as} is specially increased, so the effect of distortion is to hasten breaking, and that also applies when the water is shoal—when D/L is small.

But breaking can also be hastened in extraneous ways. In deep water, for example, secondary waves become steeper when they happen to be on the crest of a primary[5]; and if they become steep enough to break, the disturbance they set up may eliminate the small margin of stability of a steep primary, and so cause the primary to break. Besides that, when they are near breaking point, their own water-speed is large, perhaps large enough to bring the combined speed due to primary and secondary up to V. But that would be a local and transitory effect, and so might fail to operate. The same considerations apply to shoal water.

Another extraneous cause of breaking is too rapid change in depth[6].

It is also possible that breaking is hastened when the waves are wind forced, for a favourable wind will increase v_{as}, while its pressure might tend to make the crest tilt forwards; and wind acting against swell should have the reverse effects. The second effect would almost certainly be small, and the first one probably so, if the waves are big enough to be of material consequence. Steep short seas scarcely matter, and can be disregarded.

Breakers by the shore may be divided into three or possibly four classes, which may merge one into the other according to circumstances:

(*a*) The clean-cut curler, entirely due to v_{as} managing to exceed V. If S_0 is large it only occurs where the beach is steep; but if S_0 is small it may also be seen where shoaling is gradual.

(*b*) A crest so steep in front that it ultimately collapses into surf[7]. That seems to occur when S_0 is small.

(*c*) Multiple lines of surf, typical of large S_0, with gradual shoaling. At the outer line, where breaking starts, the water merely begins to trickle down the wave front, and with swell that is the stage at which surf-riding becomes feasible.

(*d*) Breaking hastened by extraneous causes, such as too rapid change in depth, or secondary waves.

The expression S_0, as used here, refers to inshore deep water steepness; and so, with swell, not its steepness in the area of generation, which may be thousands of miles away[8]. It will be taken as $0{\cdot}05$, $0{\cdot}025$, $0{\cdot}01$, to represent a heavy sea, a moderate sea, and a long low swell; and its description as large or small in the above classification of breakers must be given a good bit of latitude.

The two relevant expressions affecting shore breakers are: $D/L = S_0 \times S/S_0 \div H/D$, where S/S_0 is a definitely calculable function of D/L, so long as the waves remain trochoidal[9]; and $S_0 = 1 \div \pi \left(\frac{S}{S_0} \times \coth\frac{2\pi D}{L}\right)$, the condition for v_{as} being equal to V, again only for trochoidal waves. On this basis breaking would start when $D/L = 0{\cdot}071$, $0{\cdot}052$, $0{\cdot}036$, and $H/D = 1{\cdot}87$, $1{\cdot}93$, $1{\cdot}97$, for $S_0 = 0{\cdot}05$, $0{\cdot}025$, $0{\cdot}01$. Of course, H/D can never exceed 2, for at that figure the beach in front of the breaker would be absolutely dry; and even with $H/D = 1{\cdot}87$ it would be almost dry, except for backwash, so that $1{\cdot}87$ may be taken as typical of a heavy sea curling over on to a steep beach. When D/L is as low as $0{\cdot}04$ the waves would be, to all intents and purposes, in the 'long' state.

In fact, this way of treating waves is not mathematically exact, for it would only apply to the Rankine type, and so not to steep waves in deep water. In shoal water, where the vertical acceleration is relatively lower, it would presumably be roughly applicable to waves of greater steepness; but whether it would be so up to breaking point, even when the beach is steep, is another matter. It leads to the results that $v_{as}/V = \pi S.\coth\frac{2\pi D}{L}$, and $v_{as}/V_0 = \pi S$; and the former gives $\pi S = \tanh\frac{2\pi D}{L}$ when breaking starts. It is merely intended to afford a primitive aspect of the circumstances of breaking, and a standard for comparison when the effect of distortion from trochoidal profile has to be allowed for, as described below.

Before leaving the subject of curlers, it will be useful to summarize the factors which may contribute towards their formation, for some of these factors may also apply to other types of breakers:

(*e*) Steepening of the crest owing to distortion, with accompanying increase in v_{as}.

(*f*) Steepening of the wave front, in so far as the wave may be approaching the 'long' state.

(*g*) Reduction in v_0 owing to ground friction.

(*h*) Reduction in v_0 owing to backwash.

(*j*) v_{as} being greater than the water speed lower down, owing to the wave not having become completely 'long'.

(*k*) The water at the surface, no longer held back by any immediately ahead, being able to cascade in a parabolic path, when it succeeds in outrunning the water lower down.

When S_0 is small, factor (*f*) may tend to predominate, D/L then being small as well. Thus bore conditions start to develop, the front of the crest becoming steeper and steeper, and the water in the crest, from surface to ground, all moving forward at roughly the same speed. Ultimately, the crest tends to become a travelling wall of water, and when it ceases to find any water in front to afford support, it collapses into surf. That seems to be the way in which breakers of class (*b*) develop, at all events when the waves manage to survive until they can break on an almost dry beach, which they often do when S_0 is small.

If shoaling is gradual, and S_0 is not small, increase in v_{as} due to distortion may result in premature breaking, with H/D measurably less than 2. As waves with large S_0 are those which really matter, and as the critical value of H/D at which such waves start to break is of practical consequence, it is worth considering in detail the circumstances which may affect this ratio. Gaillard[10], who took many measurements to ascertain its value, wrote:

(*l*) "With this relation established, it will be possible, in many cases, to determine in advance the maximum wave which will assail a given structure". For, naturally, if the soundings cause the heavier seas to break away from the shore, only the remains of their energy will reach the structure.

(*m*) He might have added that, in similar circumstances, some measure of protection would be afforded to inshore anchorages;

(*n*) and that as breaking across a harbour entrance makes the harbour inaccessible, quite apart from any question of draught, H/D determines the state of the tide at which it becomes safe to enter; or, for a tideless sea, the depth of dredging necessary to keep the entrance always open.

Now Gaillard found that, in still air, breaking started, on the average, with $H/D = 0{\cdot}5$, if the slope of the bottom was 1 in 12, but ranged up to $H/D = 1{\cdot}0$ for a slope of 1 in 100. He accounted for this by suggesting that with slope 1 in 12, undertow would acquire greater speed, and so hasten breaking; but with gradual shoaling there is usually more than one line of surf, and there can scarcely be undertow at the outer line, where breaking starts. It is true that he also refers to Airy's theory as to the effect of rapid change in depth[6], but not in this connexion, presumably because he considered that its effect here would probably be small. But the point should not be entirely lost sight of, for some definite explanation is surely called for, Gaillard's measurements giving results directly in conflict with Airy's theory of 'long' waves[11]. That theory seems to indicate that with gradual shoaling distortion should, so to speak, be cumulative, in the sense that it would continue to increase even if, at some given stage, shoaling were to cease. In that case breaking should start with smaller H/D if the slopes are flatter, and not steeper, as Gaillard found. It looks as if the question calls for further explanation.

But Gaillard also found that "for a given locality and a given slope—with a strong wind blowing in the direction of wave travel", $H/D = 0{\cdot}8$; "while with an equally strong wind blowing in the contrary direction", $H/D = 1{\cdot}4$. He does not specifically give the slope, but from the context it was probably 1 in 100.

This may, to some extent, be accounted for by the direct effects of a favourable wind, in tilting the crest, and speeding up the surface water, but as already hinted, this could scarcely explain such a large change in the critical value of H/D, and so the possibility of secondary waves constituting the main reason has been looked into. Such waves could only be present with an onshore wind, for with the wind off the shore, the fetch between beach and outer line of breakers would be too short for them to develop, even if the surf did not wipe them out as soon as they started to form.

But when dealing with waves having S_0 and H/D both fairly large, so that D/L is neither very large nor very small, one is confronted with the initial difficulty that no theory seems to have been evolved to show how such waves should behave; so the expedient of assuming trochoidal state in the first instance, and then considering the general consequences of distortion, has to be adopted. For trochoidal waves at the three stages, $H/D = 0{\cdot}8$, $H/D = 1{\cdot}4$, and after fully deferred breaking, the conditions would be as shown below:

S_0		0·05			0·025			0·01	
H/D	0·8	1·4	1·88	0·8	1·4	1·93	0·8	1·4	1·97
D/L	0·105	0·08	0·071	0·075	0·060	0·052	0·05	0·04	0·036
S	0·085	0·115	0·135	0·06	0·085	0·10	0·04	0·055	0·07
v_{as}/V	0·46	0·76	1·00	0·43	0·73	1·00	0·405	0·705	1·00
v_{as}/V_0	0·27	0·36	0·42	0·19	0·265	0·32	0·125	0·18	0·22
Diff.		0·095	0·06		0·075	0·05		0·055	0·04

So with $H/D = 1{\cdot}4$, v_{as} would be deficient to the extent of 25–30 per cent of V; and as there cannot be any secondary waves with this critical value, the cause must be ascribed to distortion. In other words, distortion makes good the deficit. When the critical figure is only 0·8, additional deficits of just 30 per cent have to be accounted for.

These percentages are based on V, which, being dependent on D/L, is a variable quantity. So, to see whether the extra deficits can be covered by the effect of secondary waves, it will be convenient to take V_0, which is a fixed figure, as the basis for percentage. Then the percentage deficits for $H/D = 1{\cdot}4$ become 6, 5, 4, but are increased to 15½, 12½, 9½, when H/D is only 0·8. But with $H/D = 0{\cdot}8$, the waves will not be so distorted as later on, with $H/D = 1{\cdot}4$; so secondary waves will have to account for percentages not definitely determinable, but certainly lying between 15½, 12½, 9½, and 9½, 7½, 5½.

Now the expression governing variation in steepness of secondary waves shows that when $D/L = 0{\cdot}105$, $0{\cdot}075$, $0{\cdot}05$, as it will do when the critical value of H/D is only 0·8, $S'/S'_0 = 3{\cdot}45$, $3{\cdot}05$, $2{\cdot}8$, and distortion would make it larger still. So as the secondaries are deep water waves, and will, therefore, break when $S' = 0{\cdot}13$, S'_0 would only have to be 0·038, 0·043, 0·046. These are quite moderate figures, and with distorted primaries they would not even have to be so large. So there is always the possibility of a comparatively substantial secondary breaking on the crest of the primary, and so causing local breaking of the primary, which once started will extend in both directions along its crest. That effect is quite normal. It is not so usual for a long stretch of crest to start breaking all at once, but a large number of quite small secondaries could cause it to do so, if their effect would not be too superficial.

In regard to the other, but less likely, possibility of breaking being started by secondary water-speed supplementing that of the primary, $v'_{as} = 2{\cdot}9\sqrt{L'}$ at breaking point[12], and whether the secondaries be of moderate length or very short, say $L'_0/L_0 = 0{\cdot}05$, or 0·01, the values of v'_{as}/V_0 calculated on that basis work out at almost exactly 0·2, 0·15, 0·1 for all three values of S_0, and so will cover the percentages to be accounted for. But it must be remembered that distortion of the primary reduces L', and so V', with the result that v'_{as}/V_0 may not be so large; so the earlier suggestion is in every way to be preferred.

It should be pointed out that secondaries steep enough to break when they are on the crest of a primary will only be conspicuous in that position, and that one must not expect to see them prominent throughout the length of the wave. The profile of an undistorted primary with small D/L would be an elliptic trochoid (tracing curve an ellipse), which is merely an ordinary trochoid (tracing curve circular) drawn with vertical scale reduced, in the present case, in the ratio $H : a_s$, that is, $\tanh \frac{2\pi D}{L} : 1$. So the fraction of the length of wave occupied by the crest, as measured at mid-height (orbit centre level), is $0{\cdot}5 - S.\coth \frac{2\pi D}{L}$, or almost exactly 35 per cent when $H/D = 0{\cdot}8$, whether S_0 be large or small, and distortion will make it still less. Since S'' will only vary from 0·025 to 0·035, the secondaries in general may almost pass unnoticed.

Discussion on shore breakers can scarcely be regarded as complete without a note on the circumstances which cause reflexion instead of breaking. The subject is in a rather indefinite state, except as regards the tidal wave, which is always reflected unless the conditions favour development of a bore. The reason seems to be that, with the tidal wave, $v_{as} = v_0$, and that its component towards the shore is always small; and with the whole body of water, from surface to bottom, moving shorewards quite slowly as a stream, breaking cannot possibly take place under normal conditions. Alternatively, for 'long' waves, and so for tidal ones, $v_{as}/V = \frac{1}{2}H/D$, while the condition for breaking is that v_{as} should equal V. Then, if D be taken as the local inshore depth, the inference would be that the tidal wave should break, even on an open coast. As that does not happen, reflexion must depend on some other condition, and the answer seems to be that it will always take place with the tidal wave, unless S is large. This also gives the clue for wind-formed waves.

For reflexion of wind-formed waves, v_{as}/V must be less than 1 at the shore, and so less than $\pi S.\coth\frac{2\pi D}{L}$. That, again, indicates that S should not exceed some given figure, if reflexion is to be ensured. That figure will undoubtedly be small for all but quite steep slopes. One cannot go further with certainty, and no observations seem to have been recorded to indicate what slopes, according to the values of S, will constitute border-line conditions. Chief interest lies in two rather conflicting requirements, for shore breaking inside a harbour contributes to quiet water, while elsewhere it may result in damage.

Reference has been made to the possibility of waves attaining the 'long' state before they start to break, if S_0 is small enough. Such waves may be of practical consequence, as, for example, on the Guinea Coast, where comparatively heavy surf can result from swell that may be only just discernible in deep water; but what follows refers more particularly to a phenomenon which may be noticed at suitable places, such as Minehead[13], where low but sharply crested waves are apt to emerge suddenly from an apparently quite flat sea, and rapidly become conspicuous, but break almost immediately after doing so.

To arrive at definite figures, it will be assumed that breaking starts when H/D has increased to unity; and as $H/D = S_0 \times H/H_0 \div D/L_0$, where H/H_0 is a definite function of D/L_0, the value of the latter ratio when breaking starts must be dependent on S_0. Further, D/L is a function of D/L_0, and shows the extent to which the waves have changed their state from deep water to 'long' on account of shoaling. Elaboration of the table in ref. 7 gives the following rounded-off figures when H/D is unity:

D/L_0	0·05	0·04	0·03	0·02	0·01	0·0075
D/L	0·094	0·083	0·072	0·058	0·040	0·035
$\frac{d(S/S_0)}{d(D/L_0)} \propto$	20	35	60	130	450	800

As the value of D/L_0 to which the waves can survive intact works out at, roughly, 0·05, 0·03, 0·014, 0·0075, when $S_0 = 0·05, 0·025, 0·01, 0·005$, only a low swell can reach the stage at which dS/dD starts to increase rapidly. But once it does so, the rate shoots up so rapidly that sudden emergence from an apparently flat calm becomes almost inevitable; and the figures show that when this happens the waves have already become 'long', in which case dS/dD would be proportional to $D^{-7/4}$. Under extreme conditions, emergence is deferred almost up to the water's edge, and thus the common occurrence of a quite calm sea just lapping on the beach for no readily apparent reason is really a logical outcome of the trochoidal theory of waves.

Thanks are due to Mr. N. F. Barber for examining and discussing the drafts of these notes, and for his advice, which has been embodied therein.

ELEMENTS AND THEIR ISOTOPES

THE Ritchie Lecture for 1945 of the Royal Society of Edinburgh was delivered by Dr. N. Feather (then at the Cavendish Laboratory, Cambridge, and now professor of physics at the University of Edinburgh), who took as his subject "The Number of the Elements". The lecture has now been published (*Proc. Roy. Soc. Edin.*, A, **62**, Pt. 2, 211; 1946). Prof. Feather commenced by tracing the development of the idea of the chemical element from its earliest beginnings until, in the last quarter of the nineteenth century, Mendeléeff's Periodic Table became accepted as fundamental. Further elucidation of the Periodic Table had to wait for the emergence of the nuclear model of the atom as described by Rutherford in 1911. This led to the Bohr quantum theory, Moseley's work, Soddy's idea of isotopy and Aston's mass analysis. Physicists found that the nucleus could be adequately specified by two parameters, Z and A: the former, the atomic number, is a measure of the positive nuclear charge, and the latter, the mass number, the nearest integer to the number expressing the mass of the corresponding neutral atom in terms of chemical oxygen as 16. The elements were defined and distinguished by their Z-values. By 1932 nearly all the different atom types had been identified and classified according to their Z- and A-values. In 1932, Chadwick discovered the neutron ($Z = 0$, $A = 1$), and the nuclear picture was much simplified by regarding the nucleus as made up of heavy particles, neutrons and protons ($Z = 1$, $A = 1$). The mass defect, or $1/c^2$ times the energy of binding of the nucleus, can be estimated as the difference in mass between that of the actual nucleus and of its constituent protons and neutrons taken separately. It is important to note that the mass defect increases approximately linearly with A; and that this, together with other known facts, leads to the conclusion that intra-nuclear forces show saturation with the α-particle as the quasi-saturated unit.

Prof. Feather then went on to consider the stability of nuclei. Certain values of A and Z are not represented among the elements. The reason for these omissions, which has been borne out by the experimental work of the last decade, is that the missing nuclei, like the elements with Z greater than 83, are all spontaneously radioactive, with the result that they have disappeared entirely, with the lapse of time, from the terrestrial globe. Artificial radioactivity, obtained by irradiating materials with α-particles, neutrons, protons, deuterons, electrons and high-energy X-radiation, and a study of the energy of the radiations emitted by these artificially radioactive substances, have demonstrated the extent to which the missing nuclei are unstable. For naturally radioactive substances disintegration occurs by the emission of α-particles or of β-particles; but for the artificially radioactive substances, only β-emission, but of two types, has so far been found to occur. Discussing this point, Prof. Feather shows that, for Z less than 84, the problem of the number of the elements, or of the number of stable nuclear species, turns essentially on the question of stability towards β-disintegration.

For Z greater than 83, the customary assumption that the onset of α-instability prevents stable species is not at all satisfactory. In 1939 neutron-induced fission was discovered, and in the following year, I. S. Petrzhak and G. N. Flerov (*J. Phys. U.S.S.R.*, **3**, 275; 1940) showed that, in the natural state, uranium undergoes fission spontaneously; for every million atoms of uranium which disintegrate with the emission of α-particles, roughly one divides spontaneously into two fragments. The probability of disintegration per unit time depends very markedly on the difference between the available energy (some 170 million electron volts for uranium) and an energy characteristic of the original nucleus and the fragments into which it divides. On a simple liquid-drop model, spontaneous fission can be shown to increase extremely rapidly in probability as Z^2/A increases, so that for Z greater than 92, spontaneous fission is practically instantaneous, leaving uranium the last terrestrially known element of the Periodic Table.

Finally, Prof. Feather discussed the limitation to the number of stable or quasi-stable isotopes of a given element, that is, the limitation to the A-values for a given Z. By examining the way in which the α-disintegration energy (or the decay constant) varies with the mass number for a particular Z, it is established that the limitation is essentially a question of the relative probability of α-emission to β-emission (either positive or negative electron emission).

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 17

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Prof. H. J. Fleure, F.R.S.: Clayton Memorial Lecture.

Sheffield Society of Engineers and Metallurgists (at the Royal Victorial Station Hotel, Sheffield), at 6.15 p.m.—Dr. N. P. Allen: "Metallurgical Aspects of Compressed Gas Cylinders".

Institution of Mechanical Engineers, Graduates' Section (at Storey's Gate, St. James's Park, London, S.W.1), at 6.30 p.m.—Mr. Ian S. Porter: "The Art and Mechanism of Weaving".

Tuesday, February 18

Institution of British Agricultural Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2 p.m.—Mr. H. P. Hall: "Milking Machines".

British Society for International Bibliography (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Mr. W. C. Berwick Sayers: "The Organization of Information for the General Public"; Miss E. Taylor: "The Bureau of American Bibliography at the National Central Library".

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Prof. S. P. Bedson, F.R.S.: "Laboratory Investigations in the Diagnosis of Virus Infections of Man".*

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Colonel J. G. Robertson: "Recent Agricultural Development in Canada" (Neil Matheson McWharrie Lecture).

Society of Chemical Industry, Agriculture Group (in the Physical Chemistry Lecture Theatre, Royal College of Science, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. E. W. Russell: "Present-day Views on Soil Cultivation".*

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 3 p.m. and 5.30 p.m.—Dr. A. Nadai: "The Flow of Metals under Various Stress Conditions" (James Clayton Lecture).

King's College, Strand, London, W.C.2, at 5.30 p.m.—Prof. J. T. Randall, F.R.S.: "A Physicist's Approach to Biology".*

Institute of Petroleum, Northern Branch (at the Engineers' Club, Albert Square, Manchester), at 6 p.m.—Mr. A. E. Hope: Illustrated Dissertation on the "Use of Petroleum Additives".

Institution of Electrical Engineers, London Students' Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Discussion on "Radio Modulation Methods—Amplitude, Phase, Frequency and Pulse" (to be opened by Mr. G. Dawson, D. Deacon and R. F. Howard).

Society of Dyers and Colourists, Huddersfield Section (at Field's Café, Huddersfield), at 7.30 p.m.—Mr. G. E. Bedford: "What Happens at the Dry Cleaners".

Institute of Physics, Scottish Branch (at the University, Glasgow)—Mr. A. J. Maddock: "Dielectric Heating".

Wednesday, February 19

Physical Society (in the Jarvis Hall, Royal Institute of British Architects, 66 Portland Place, London, W.1), at 3 p.m.—Meeting to discuss the formation of an Acoustic Group. Dr. Alex Wood: "The Contribution of Acoustical Science to Allied Studies".

Chemical Society (joint meeting with the Royal Society of Arts, at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Sir Harold Hartley, F.R.S.: "A Century of Chemistry".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Microscopical Society (in the Hastings Hall, British Medical Association, Tavistock Square, London, W.C.1), at 5 p.m.—Mr. E. Wilfred Taylor: "The Practical Application of Phase-Contrast to the Biologist's Microscope"; Dr. A. F. W. Hughes: "Phase-Contrast Films of Tissue Cultures". (Discussion to be opened by Prof. L. C. Martin).

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. H. Davies: "The Design of High-Fidelity Disc-Recording Apparatus".

Institution of Civil Engineers, North-Western Association (joint meeting with the Liverpool Engineering Society, at the Municipal Annexe, Dale Street, Liverpool), at 6 p.m.—Mr. J. C. King: "The Static and Dynamic Testing of Aircraft".

Royal Institute of Chemistry, London Section (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Dr. G. H. Lees: "British Oilfields and Oil Exploration".

Thursday, February 20

Institute of Fuel, North-Western Section (at Radiant House, Bold Street, Liverpool), at 2.30 p.m.—Dr. E. G. Ritchie: "A Review of the Work of R/16 Committee".

Institution of Mechanical Engineers (at the College of Technology, Sackville Street, Manchester 1), at 2.30 p.m. and 5 p.m.—Dr. A. Nadai: "The Flow of Metals under Various Stress Conditions" (James Clayton Lecture).

Royal Society of Arts, India and Burma Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Lewis L. Fermor, F.R.S.: "The Value of Geological Survey in India's Economic Development".

Chemical Society (in the Chemistry Lecture Theatre, The University, Liverpool), at 5 p.m.—Prof. E. L. Hirst, F.R.S.: "Recent Developments in the Chemistry of Starch and Glycogen".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Herbert S. Sichel: "An Experimental and Theoretical Investigation of Bias Error in Mine Sampling, with special reference to Narrow Gold Reefs".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. A. M. Turing: "The Automatic Computing Engine".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. J. R. Mortlock and Mr. C. M. Dobson: "Neutral Earthing of Three-Phase Systems, with particular reference to Large Power Stations".

Chemical Society (in the large Chemistry Theatre, University College, Nottingham), at 7 p.m.—Prof. E. G. Cox: "Crystal Analysis and Stereochemistry".

Textile Institute, Yorkshire Branch (at the Midland Hotel, Bradford), at 7 p.m.—Prof. J. B. Speakman: "Proteins and Plastics".

Women's Engineering Society (at 35 Grosvenor Place, London, S.W.1), at 7 p.m.—"Plastics".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Chemical Society, Society of Chemical Industry and Royal Institute of Chemistry, Edinburgh and East of Scotland Sections (at the North British Station Hotel, Edinburgh), at 7.30 p.m.—Dr. Neil Campbell: "Fluorescence".

Textile Institute, Belfast Branch (at the College of Technology, Belfast), at 7.30 p.m.—Dr. F. C. Wood: "Recent Developments in Cellulose and Wool Science and Technology".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 8 p.m.—General L. M. J. Van Hoof: "Trypanosomiasis in the Belgian Congo" (Second Chadwick Lecture).

Friday, February 21

Association of Applied Biologists (in the Main Lecture Theatre, Huxley Building, Exhibition Road, London, S.W.7), at 2 p.m.—Annual General Meeting. Dr. C. B. Williams: "The Field of Research in Preventive Entomology".

Chemical Society (joint meeting with the University College of Southampton Chemical Society, in the Physics Lecture Theatre, University College, Southampton), at 5 p.m.—Sir Ian Heilbron, F.R.S.: "The Chemistry of Vitamin A".

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. W. D. Owen: "Quantitative Tests on Finished Mouldings".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. E. L. Diamond: "The Development of Locomotive Power at Speed".

Institute of Physics, Industrial Radiology Group (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. W. L. Harper: "The Organisation of Aircraft Radiology during the War".

Society of Dyers and Colourists, Manchester Section (in the Lecture Theatre, Gas Department Showrooms, Manchester), at 6.30 p.m.—Mr. G. S. Egerton: "The Aspect of Light on Dyed and Undyed Cotton".

Institute of the Plastics Industry, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—"Costing and Estimating of Mouldings, Compression, Injection and Transfer".

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 7 p.m.—Mr. G. Dakin: "Researches in Spinning and Doubling".

Textile Institute, Dublin Branch (at the Mansion House, Dublin), at 7.30 p.m.—Dr. F. C. Wood: "Recent Developments in Cellulose and Wool Science and Technology".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. M. L. Oliphant, F.R.S.: "Problems and Techniques of Modern Nuclear Physics".

Saturday, February 22

Institution of Chemical Engineers, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 3 p.m.—Mr. V. G. Jenner: "Fuel Economy in a Small Factory".

Nutrition Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1)—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Clinical Chemist to be responsible for tests and investigations of a chemical nature in the Clinical Pathology Department—The Secretary, University College Hospital Medical School, University Street, London, W.C.1 (February 28).

Chemists (2) for Research Scholarships, and a Chemist for a Research Fellowship, in connexion with fundamental work on the oxidation and constitution of coal—Prof. S. G. Ward, Department of Chemical Engineering, The University, Edgbaston, Birmingham 15 (February 28).

Lecturer in Fuels or Fuels and Refractories—The Secretary, The University, Edmund Street, Birmingham 3 (February 28).

Veterinarians to specialize in Poultry in the New Zealand Department of Agriculture—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (February 28).

Lecturers (2, men or women) in Mathematics—The Registrar, University College, Southampton (February 28).

Lecturer in the Department of Mathematics—The Registrar, Queen Mary College, Mile End Road, London, E.1 (March 6).

University Photographer—The Registrar, The University, Leeds 2 (March 15).

Principal Scientific Officer (Electrical Engineer), and a Principal Scientific Officer (Physicist) in the Royal Aircraft Establishment of the Ministry of Supply—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1797 (March 15).

Senior Experimental Officers (8) at the National Gas Turbine Establishment of the Ministry of Supply—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1794 (March 15).

Superintendent of Engineering Services, and a Superintendent of the Chemical Engineering Division, at a research establishment of the Ministry of Supply—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1795 (March 15).

Senior Engineer at the National Gas Turbine Establishment—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1798 (March 15).

Research Assistant in the Department of Botany—The Registrar, The University, Leeds 2 (March 31).

Technical Development Officer—The Establishment Branch (Room 266), Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1 (March 31).

Lecturer in Physiology—The Secretary, Queen's University, Belfast (May 1).

Associate and Full Professorships in the Department of Physics—The Head of the Department of Physics, University of British Columbia, Vancouver, B.C., Canada (May 12).

Assistant Biochemist—The Medical Superintendent, Dudley Road Hospital, Birmingham 18.

Lecturer in the Department of Electrical Engineering, and a Lecturer in the Department of Mechanical Engineering—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Information Officer (graduate in engineering or metallurgy, experienced in welding practice)—The Director of Research, British Welding Research Association, 29 Park Crescent, London, W.1.

Biochemist or Chemist for research on fundamental problems related to the nervous system—The Director, Neuropsychiatric Research Centre, Whitchurch Hospital, Cardiff.

Laboratory Assistant (female) for chemical and spectrographic laboratory—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen.

FREEDOM IN DEMOCRACY

SCIENCE, like British democracy, as Mr. Alderton Pink emphasizes in his stimulating little book, "The Challenge to Democracy"*, has grown up in association with religious freedom, from which sprang freedom of thought, of the Press, of teaching, of assembly—of all that we understand as cultural freedom—as well as economic freedom, though he might well have added that neither the implications nor the responsibilities of even comparative economic freedom appear to be appreciated. The issue between science or democracy itself and any kind of authoritarianism turns on the principle that the spiritual life of the individual is a region in which the State is not competent to interfere; to that extent the control of science by any outside body would eventually strangle science. In maintaining its autonomy science can play a decisive part in preserving such freedom as man has gained hitherto, and even help to enlarge it. But to do this, science must enlarge its conceptions of truth and clarify its conceptions as to the area of liberty. Such books as Prof. F. A. Hayek's "The Road to Serfdom" may conceivably have hindered rather than helped the fundamental thinking on this point that is a primary need, and Mr. Alderton Pink's chapters are by contrast a welcome stimulus. Provided cultural freedom is preserved, the democratic State is not undermining its own principles by undertaking the control of economic affairs. We must, it is true, recognize that the traditional liberty of the individual will be affected to a considerable extent, but the present alternative to serfdom is surely a system of public control under which lesser liberties are sacrificed in order to secure the greater.

The danger to which Prof. Hayek has directed attention must nevertheless not be belittled, and it is essential that the community as a whole be allowed to decide to what extent planning operations are to be allowed to encroach on individual liberties. That is as true of planning in the scientific field as in the wider field; but the scientific community must decide its own limitations, and the danger of outside control will disappear as the education of the whole community advances. We need a re-statement of the democratic principles of liberty of thought and expression. While we must preserve at any cost the freedom to publish in all sincerity the political, the artistic or the religious faith we hold, and to persuade others to accept that faith; the freedom to pursue research into any branch of human knowledge for the advance of science and scholarship; and the freedom to give expression to thought and feeling for the purposes of art, the governing motive cannot be disregarded. The freedom we guarantee must be freedom to act with a worthy purpose.

Mr. Pink develops his argument here with reference to the dangers attendant on some of the abuses of cinema and Press, and he argues that public supervision can be combined with genuine professional freedom and independence. The particular methods of securing such a balance have to be worked out by the democratic communities if they are to promote a healthy cultural life, and this is one of the problems that confronts the scientific community at the present time. Its complexity is well illustrated by the discussion provoked by Sir Robert Robinson's recent commendation, in his anniversary address to the Royal Society, in regard to the independence of the universities and unfettered freedom of research, and the refusal of many universities to accept theses that cannot be published.

---

* The Challenge to Democracy. By M. A. Pink. Pp. 118. (London: Faber and Faber, 1946.) 10*s*. 6*d*.

What has to be recognized in this matter is that the positive government which is implied in a social security State and in conditions of full employment is not only bound to curtail the economic freedom of the individual to some extent; but it also involves obligations on the part of the worker, as well as of the employer and the State. Mobility of labour and abrogation of the right to withhold labour are within reasonable limits part of the price which has to be paid for social security, with all its implications for cultural freedom; and unless that price is paid, social security and much with it will collapse.

Science cannot be pursued entirely regardless of the material needs of mankind. That future depends rather on the man of science helping the community in which he works to understand his primary loyalty to the search for truth, the method by which he secures his results and the price which has to be paid for them; and in co-operating with the community in the defence of the freedom of the other cultural activities of mankind.

That, however, is only part of science's contribution to the defence of freedom and of the evolution of a new world order. An equally important contribution is that which Dr. G. H. Monrad-Krohn has indicated in his address "*Homo sapiens* and the Peace Problem: a Plea for a more Comprehensive Survey"*. Before we build a new world order that will ensure international peace, we must know very much more about the difficult country across which the road to peace must be laid. We must understand not merely the ethical demands which an international society makes, but also a great deal more about the psychological peculiarities of mass mentality that constitute so serious a threat to a rational order.

Dr. Monrad-Krohn sets forth the contribution which psychology, and especially social psychology, has to make. He urges that institutes should be created for the study of problems in social psychology, with the dual purpose of research and the exposition of its results. Nor would he confine the study of social psychology to the universities: it should begin in the schools and should be obligatory for all politicians, school-teachers and journalists. He thinks that the leading people in broadcasting and in the cinematograph world should have a knowledge of mass psychology, so as to enable them to realize their great responsibilities. His attitude to the Press, broadcasting and the cinema, advocating full freedom under full responsibility, is similar to that of Mr. Alderton Pink. He is under no illusions as to the pace of advance. Social psychology, although of steadily increasing importance, is still in its youth; but this highly stimulating paper makes constructive suggestions for a programme to avert the great dangers which at present confront us, and to repair the moral deterioration which any war inevitably entails.

The plea for attention to psychological as well as technical factors in the rebuilding of the world is not to be set lightly on one side; and Dr. Monrad-Krohn is also fully aware that while this educational campaign is proceeding, not merely binding international legal arrangement but also a heavily armed international police force and a very close control of armaments everywhere will be essential. But he does point a way forward that must be explored, and he indicates a contribution which the man of science can, as citizen, do something to promote.

What needs to be remembered is that the elimination of war as a means of dealing with international disputes and the development of a world order, as indeed of an ordered State, demand not merely improvements in the efficiency of government, but also a positive contribution from the individual citizen in the form of the discharge of certain responsibilities. Social psychology may come indeed to make a vital contribution to that intelligence system which is so essential an element in the integration of national, local and sectional interests into policy and a plan of action conceived and accepted by all. But a new spirit is required to vitalize the body politic—a unifying purpose as well as a habit of responsible criticism—if men and women are to be capable of accepting the sacrifices, at every cultural, social or economic level, which a properly planned democratic order must continually demand in the interests of the whole.

While his approach is different, that is also a main theme of Mr. W. A. Gauld's "Man, Nature and Time"*. He insists that man rather than Nature gives direction and purpose in history, and that the world as we experience it to-day is a man-made world to a much greater degree than we allow; then he challenges outright much of the pessimistic thought to-day and the tendency to drift. He presents a picture of a dynamic world, emphasizing its complexity and interrelations in much the same way that Dr. Barlow did in "The Discipline of Peace", rejecting the physical determinism which accounts for events by conditions. It is a challenge to thought as well as to action, and although he points less clearly to the moral factors than Mr. Pink, Mr. Gauld is equally convinced of the importance of spiritual values and the necessity for a moral basis for the world order which he sees as in the nature of things and not merely as an idealist concept.

There is a realism and a confidence in this modest introduction to world study which are invigorating, and will be needed in the task of education to which Mr. Gauld also summons us. His book is indeed more challenging than Prof. Herman Finer's "The Future of Government"†, for it is only in the last chapter that Prof. Finer rises above a pedestrian chronicle of events and surveys the future task of democracy. In that chapter, however, he does something to justify the title of his book, and comments which elsewhere are overlaid with detail are seen in a truer perspective, even if there is little that is new.

† The Future of Government: being a Continuation of the "Theory and Practice of Modern Government". By Herman Finer. Pp. ix+198. (London: Methuen and Co., Ltd., 1946.) 10*s*. 6*d*. net.

Prof. Finer, no less than Pink and Gauld, recognizes the influence on the present situation of deep individual complexities and insecurity regarding spiritual values; and he sees too that the threat to freedom comes, not only from dictators afraid of its consequences, but also from the sharpening of control by each nation over its scientific and technical community by such means as the Official Secrets Act, and pledges to an international organisation permitting an inspectorate full access to all plants. He voices explicitly the continuing anxiety whether the basic liberties, freedom of expression and debate, of change of government, of association and of impartial judgment before the courts can stand up against the high degree of organisation, self-control and the external controls involved in national and international organisation.

Prof. Finer has a clear view of what is at stake, both for science itself and for the democratic society in which it can best flourish, and the price to be paid is set down fairly. It is an unending task in science as well as in government to protect the open way for the communications of the gifted, and equally to maintain the proper conditions by which the multitude's reflexion upon them is promoted; and scientific men are at last coming to appreciate the dangers which have followed the neglect of the latter task. The relation of knowledge to power is an unending and ever-changing problem, and grows the more intimate as the knowledge needed for leadership, direction and decision in the world grows more complex. Effective democratic government, Prof. Finer observes, requires the interplay of the general body of citizens and the statesmen; not the exclusion of eminence but its contributive uses; and events at home and abroad are testifying to the truth of his further comment that the unity of a dynamic society is a product not simply of mass but of representative creativeness at a responsible centre, and that the fellowship which marks a nation in its progress is in part the product of men at the responsible summit who can relate the needs of the whole social situation to the fragmentary contending wants of millions of aggressive individuals.

Planning and organisation there must be in government, no less than in science, if chaos and waste are not to reign supreme. But beyond this there must be that vision, that sense of purpose, of moral and spiritual values that will give unity to its activities and draw together in harmony and fellowship the myriad units who pursue these activities or whose wants are satisfied by them. The major question for our time is whether this generation has the courage, imagination and will to master the modern social techniques and to guide them in the right direction, and on this point Prof. Finer is silent. We turn, therefore, to Dr. Monrad-Krohn, the late Prof. K. Mannheim and Mr. Alderton Pink for guidance and suggestions on developing the moral qualities of the peoples, and the changed attitude to education—and especially to adult education—which can alone cure the social diseases so evident and so widespread to-day. These can provide the ethical foundations for the new institutions and instruments of government, regional and functional, national and international, which mankind must evolve to safeguard its great cultural heritage. They can ensure the greater freedom of mind and culture, of communication and utterance in which alone science and the arts can flourish, and which to-day are so sinisterly threatened by the very powers which science has put into the hands of men to command.

NUCLEAR EXPLOSIVES, NUCLEAR POWER AND WORLD AFFAIRS

One World or None

Edited by Dexter Masters and Katharine Way. (Whittlesey House Publication.) Pp. xi+79. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 5*s*.

THE atomic bomb is one great cause of political uncertainty in the world to-day. Although the difficulty of reaching a satisfactory solution of the problem is largely confined to the relationship between the United States, the great Power which possesses the bomb, and the U.S.S.R., the other great Power of to-day which does not yet have stocks of the revolutionary weapon, the significance of the new discoveries is probably greatest of all for Great Britain and the Commonwealth. The concentration of industry and population in the cities of the British Isles, the island isolation which has been such an asset in the past, but which now prevents adequate dispersal or effective interception of fast aircraft, our dependence on sea communications and the very nature of our climate which offers cover to the raider, all combine to make us more vulnerable than any other industrial country. At the same time, the probability that atomic energy will provide abundant power which could counteract many of the disabilities of large parts of the Commonwealth, which are ill-endowed by Nature, means that we have a special positive stake in the elimination of the war-like uses of atomic energy and rapid development of all its peaceful applications.

The collection of essays in the book under review represents an early analysis of the situation from the point of view of American writers. The authors are some of the best-known men of our day in physical science, in military arts and in constructive journalism. Some of the articles are brilliantly written, and reveal the grave concern for the future of civilization and of science which is felt by all men whose thoughts go beyond the barriers of nationalism. The foreword is by that great scientific humanitarian, Niels Bohr, who, in the days before the bomb was dropped, taught all who worked with him how to think constructively about the political problems which use of the bomb would engender. Subsequent events have shown clearly how right he was and how sad it is that his ideas were ignored.

The technical facts about the bomb and its control and the peaceful possibilities of atomic energy are discussed by such brilliant scientific writers as Oppenheimer, Ridenour, Condon, Morrison, Einstein, Urey and Bethe, while General Arnold shows why, despite the claims of some interested parties to the contrary, the bomb and its future possibilities do make nonsense of great navies, great armies and air forces. It is clear that if preparation for war is to continue to be the principal peace-time preoccupation of men, the future lies with small highly trained specialist corps to disperse the new agents of destruction and to do what little is possible to intercept them and to counter their effects.

Almost all these writings can be translated readily to refer to the British Commonwealth. Much of the wisdom contained in them has been incorporated in the Lilienthal–Baruch plan for control of atomic energy, which is now under consideration by the United Nations. Since the end of the War, Oppenheimer, Urey and others in the United States have devoted their whole time to consideration of these problems, and behind anything constructive which has emerged lies the determination and great understanding of these men. Despite the greater urgency of the problem for us in Britain, no one here has emulated this achievement, probably largely because public activity by a man of science in Great Britain brands him at once as an 'awkward fellow'. During his recent visit Prof. Urey remarked that "there is a comparative lack of a sense of urgency here", and perusal of these articles from the United States may help to awaken a more vital interest.

In the absence of corresponding British documents, the U.S. "Smyth Report" and "One World or None" form companion books of information for all men of science who have feelings of responsibility for the effects of their work on world affairs.

M. L. OLIPHANT

RENEWAL OF A CLASSIC

The Common Sense of the Exact Sciences

By William Kingdon Clifford. Edited and with a Preface by Karl Pearson. Newly edited and with an Introduction by James R. Newman. Pp. lxvi+250. (New York: Alfred A. Knopf; London: Sigma Books, Ltd., 1946.) 15*s.* net.

THIS volume is the product of many minds. Clifford left the manuscript of "The Common Sense of the Exact Sciences" in a very incomplete state at his death in 1879, and the work of editing it for publication was entrusted to Prof. R. C. Rowe, who himself died in 1884 with his task unfinished. It was then taken in hand by Prof. Karl Pearson, and eventually appeared in 1885 and passed through various editions. An American publisher has now reprinted it, with a preface by Earl Russell and a 48-page introduction by Mr. James R. Newman, who has also added many footnotes.

The book has been so well known for generations —Russell tells us how he read it "with passionate interest" nearly sixty years ago—that a description in detail would be superfluous; all that is called for seems to be some comments on its general character and on the contributions of its latest editor.

Perhaps the only criticism that might be made of the original work was the disparity between different chapters, as regards difficulty of comprehension. The early part (that a sum is independent of the order of adding, a product is independent of the order of multiplying, and so forth) can be understood by a young child, while the treatment of, for example, the curvature of space, which comes later (though the ideas are explained with wonderful lucidity), calls for considerable intellectual power and some maturity of mathematical knowledge (indeed, I knew personally a university professor of natural philosophy, of the generation next above mine, who to the day of his death refused to believe in the possibility of non-Euclidean geometry). The reader is liable to be either bored by the laboured discussion of the obvious, or unable to grapple with the more advanced subjects.

The editor, Mr. Newman, has done his work well: his footnotes are admirable, and show both learning and judgment. But the situation was a difficult one; Clifford died before the modern theory of number was discovered and before his brilliant idea of geometrizing physics had been brought to its glorious fruition by Einstein; and to graft notions of these theories on his book was scarcely possible without complete re-writing. The effect of trying to do it is sometimes rather as if an explanation of the multiplication-table had notes warning the infant reader that the multiplication of quaternions is non-commutative.

EDMUND WHITTAKER

PHILOSOPHERS AND HISTORIANS

Leviathan or the Matter, Forme and Power of a Commonwealth, Ecclesiasticall and Civil

By Thomas Hobbes. Edited with an Introduction by Michael Oakeshott. Pp. lxvii+468. (Oxford: Basil Blackwell, 1946.) 8*s.* 6*d.* net.

On Liberty and Considerations on Representative Government

By J. S. Mill. Edited with an Introduction by R. B. McCallum. Pp. lix+324. (Oxford: Basil Blackwell, 1946.) 8*s.* 6*d.* net.

Prophets and Peoples

Studies in Nineteenth Century Nationalism. By Prof. Hans Kohn. Pp. vii+213. (New York: The Macmillan Company, 1946.) 10*s.* 6*d.* net.

Politics and Morals

By Benedetto Croce. Translated from the Italian by Salvatore J. Castiglione. Pp. 138. (London: George Allen and Unwin, Ltd., 1946.) 8*s.* 6*d.* net.

THE seventeenth century, with its forcing ground of ideas during the Civil War and Commonwealth, can now, more clearly than ever, be seen as one of the decisive periods of modern history for England, and, through England, for Europe. The English Revolution, like its successors in America, France and Russia, which drew inspiration from it, has left an ineffaceable mark on world history. It is well, then, that at this time, when accusations of reaction and stagnation are in the air, we should be reminded of the pioneering work of the seventeenth century that has ensured three centuries of the steady development of what we recognize to-day as the British conception of democracy. One of the most daring and original minds of the revolutionary era was that of the philosopher, Thomas Hobbes, whose classic and long hotly debated "Leviathan" has now been re-issued for the student, with a striking introductory essay by Mr. Michael Oakeshott. It appears, properly enough, with John Locke's equally famous, and more obviously influential, "Civil Government", edited by Mr. J. W. Gough, and with John Stuart Mill's Victorian classics, "On Liberty" and "Representative Government", introduced by Mr. R. B. McCallum, the three volumes being the first of a new series of "Political Texts" which should win a high place in the esteem of the student of political philosophy.

Hobbes has so often been dismissed in recent times as an early "Fascist" that it is stimulating to find Mr. Oakeshott insisting on his individualism and on his opposition to absolutism and arbitrary rule: "Nor is . . . the Leviathan a designed destruction of the individual; it is, in fact, the *minimum* condition of any settled society among individuals. . . . Hobbes, without being himself a liberal, had in him more of the philosophy of liberalism than most of its professed defenders." To this view may be opposed a sentence from Dr. G. P. Gooch's British Academy lecture on Hobbes, delivered in 1940: "Hobbes was the foe of the idealism, the individualism, and the method of compromise which have given Western civilisation its colour and shape". With Mr. Oakeshott's clear and readable text before him, the student can form his own opinion and ponder the relevance of this undoubted masterpiece for the fundamental political and social problems of our own day. Above all, he can relish the force of Hobbes' statement, a challenge in its own day, that the State was formed for man, and not man for the State: "For by art is created that great LEVIATHAN called a COMMONWEALTH, or STATE, in Latin CIVITAS, which is but an artificial man; though of greater stature and strength than the natural, for whose protection and defence it was intended".

Locke has a less general validity; but as the apologist of the Glorious Revolution of 1688 his influence on English and American political development has been considerable, as Mr. Gough is concerned to show. "The end of government," Locke wrote, "is the good of mankind", and he drew a distinction between society and State, which Hobbes had confused, and thereby justified the English tradition of social activity apart from the State which was particularly fruitful in the nineteenth century, and created the political atmosphere in which J. S. Mill's work was conceived. "With the English-speaking peoples," says Prof. Kohn in an essay on Mill in "Prophets and Peoples", "the initiative rested with society, not with the state." Conditions have changed in eighty years, but the closing passage of "On Liberty" has still a real meaning and message: "A government cannot have too much of the kind of activity which does not impede, but aids and stimulates, individual exertion and development. The mischief begins when, instead of calling forth the activity and powers of individuals and bodies, it substitutes its own activity for theirs. . . . The worth of a State, in the long run, is the worth of the individuals composing it."

"Prophets and Peoples" is a collection of essays on various national and nationalist philosophers of the past century, Mill, Michelet, Mazzini, Treitschke and Dostoevsky. They are sound and thoughtful studies, which whet the appetite for Prof. Kohn's forthcoming study of nationalism during the period. But what is most striking as one reads the book is the change in mood and outlook as one passes from the three Western European thinkers to Treitschke and Dostoevsky: many of our recent difficulties are revealed in the contrast.

Prof. B. Croce has long been famous as the philosopher and historian of liberalism, and this most recent book, "Politics and Morals", consisting of essays written, apparently, before the War, re-states his faith in Western democracy on liberal foundations. "In the final analysis," he says, in words that recall Mill, "States are what the men who constitute them continually make them. . . . The liberal conception is not meant for the timid, the indolent and the pacifist; but wishes to interpret the aspirations and the works of courageous and patient, of belligerent and generous spirits, anxious for the advancement of mankind and aware of its toils and of its history." The emphasis, again, is on men, not institutions, and the moral is clear. MAURICE BRUCE

FRUIT GROWING

Hardy Fruit Growing

By Sir Frederick Keeble and A. N. Rawes. Second edition. Pp. xi+342+21 plates. (London: Macmillan and Co., Ltd., 1946.) 20*s*. net.

THE first edition of this book appeared in 1936; it is a testament to the distinguished authors that so little change has had to be made in this new edition. A few deletions of material now out of date, a new paragraph here and there to amplify some point in the light of new knowledge, more especially in the section dealing with cultivation and manuring, and a more extensive revision of the sections on the pests and diseases of individual fruits by Messrs. Fox Wilson and Green of the Royal Horticultural Society's laboratories, are all that have been found necessary.

The avowed primary object of the book, to provide amateur and professional gardeners with a sufficient guide to enable them to grow fruit well, is admirably achieved. The first half of the book, on planting, upkeep, propagation and storing, is meant to be read and, coming from the pens of two such able writers, is most eminently readable. It contains a great amount of factual experiential teaching; the only criticism one might make is that a writer such as Sir Frederick Keeble, who possesses to such a unique degree the gift of exposition of science to the non-scientific, might have dilated more on the physiological principles underlying the practice of fruit growing. To a greater and greater extent in these days the enthusiastic amateur wants to know the 'why' as well as the 'how', and few can explain it better than Sir Frederick. Many thousands will always remember with delight his popular scientific leaders of the *Gardener's Chronicle*, and will wish that more of that easy, intimate style could have been infused into the present work.

The second part is a reference section dealing with each of the main hardy fruits in turn, discussing varieties, pests and diseases, and special points of culture. In the selections of varieties for different purposes one sees the hand of the second author, than whom few know fruit varieties better. No one would quarrel with his choices, though perhaps more of the newest varieties of outstanding merit might have been included in this second edition. A notable example is the omission of the plum variety 'Marjorie's Seedling', one of the best all-round plums for private and commercial grower alike, though admittedly not of the very first quality for dessert flavour.

The sections on the pests and diseases of the separate fruits are admirable examples of succinct information without a wasted word; perhaps the use of D.D.T. is too new and experimental as yet to be included in a text-book of this kind, though its value in the control of apple blossom weevil, to take a single example, would seem to be so great as to have called for some mention, however cautious.

The last section of the book, dealing in an introductory way only with commercial fruit growing, is disappointing. It is too brief to be of any value to the established grower, yet too detailed to be interesting to the amateur. The inclusion of some simple physiology in the first section, as we have suggested, would allow of the omission of this part without loss to the value or size of the work. In particular, there seems no reason whatever for the chapter on the very specialized subject of forcing strawberries under glass. No other fruits under glass are dealt with, so why pick out this one example?

The public to whom the book is primarily addressed will, however, find all the practical information they can want within the book, and it will stand as one of the most valuable works on the subject.

BIOLOGY OF THE TREMATODA

The Trematoda

With Special Reference to British and other European Forms. By Dr. Ben Dawes. Pp. xvi+644. (Cambridge: At the University Press, 1946.) 52*s*. 6*d*. net.

Every teacher of biology will no doubt agree that we have for a long time needed a single volume which gives, in the English language, a detailed account of the trematodes written from the point of view of the biologist. The medical man and the veterinarian, confronted with the serious diseases which some species of trematodes cause, have at their disposal excellent accounts of these pathogenic species which necessarily lay emphasis upon the economic, therapeutical or epidemiological aspects of the problems which they raise. In these modern text-books of parasitology two developments are clearly revealed. One is that enormous advances have been made during recent years in our knowledge, not only of the trematodes, but of other helminths also. The second is that the men who gained this new knowledge quickly learned that parasitic organisms cannot be controlled unless they are first understood, and that they cannot be understood unless they are studied precisely as the biologist studies them, namely, as organisms inseparable from their environments and following a certain mode of life in relation to other living things. The parasitologist, therefore, who wishes to control or minimize the damage inflicted upon man and his civilization by parasitic organisms must be primarily a biologist; and nothing shows this more clearly than the fact that most of the advances which we have made in the control of parasitic organisms have been due to increases in our knowledge of their biology. Every modern text-book of parasitology recognizes this and devotes considerable space to the biological background upon which specialized information depends.

Dr. Dawes does not attempt to compete with these more specialized text-books of parasitology. His aim is rather to place at the disposal of everybody a much more detailed account of the biology of the trematodes than any text-book of parasitology could give. It is likely that the medical man and the veterinarian, well qualified by their experience to realize the extent of the service which he has done for them, will be among the first to echo his hope that British biologists will give more attention to the trematodes. Certainly, biologists will find in this book plenty of problems which require further study; for as the author himself says, they are indicated on almost every page and they are varied enough to occupy a variety of interests, whether these be physiological, biochemical, morphological or taxonomic. For those who like especially intricate problems requiring a knowledge of more than one branch of biology there are the problems of host relationships and the immunological problems associated with them.

The book begins with a chapter on the Platyhelminthes which places the trematodes in their zoological setting; it contains also a section on the derivation of the names of trematodes, which introduces the student to the mysteries of zoological nomenclature. The structure of the Monogenea and the Digenea is then described, and the next section, which occupies about half the book, is devoted to the classification of both these orders and to the characteristic features of their suborders and families. An immense amount of information is compressed into this section. Keys to the families are given, and there is a useful table of the general characters of the main families of the Digenea. A classification of the various kinds of cercariæ follows, and this is succeeded by chapters on the reproduction, geographical distribution and phylogeny of the trematodes and on their life-histories and the biology of their larval and adult phases. There is an interesting short historical account of work done on the trematodes, and useful notes are given on the collection, preservation, fixation and staining of both the larvæ and the adults. The book ends with a list of nearly 1,600 references to literature. The fact that only about half of these are in English is a measure of the relative amount of work done on trematodes in Britain and in other countries. Many of the papers mentioned are not readily accessible, so that the incorporation of their contents in the pages of this book is a useful service. The index is adequate; but it might be improved in the future editions, for which there will certainly be a demand.

Even a short review of this book cannot be concluded without a reference to the grace and simplicity of the author's style and to the excellence of the publishers' contribution to the making of the book. It may be argued that it is no part of the function of a scientific book to give pleasure to the reader; but the sufficient answer to that argument is the fact that many books written by men of science do give pleasure to their readers and are among the best examples that we have of English literary style and of British book-production. This is such a book, and the reason for it is possibly to be found in the author's statement that, after more than twenty years as a student and a teacher, he has not lost his wonderment at the phenomenon of parasitism. Wonderment? Is that the secret of it all? So long as we can feel that wonderment and can discover and foster it in the young people whom we teach, so long will science progress, and so long will understanding strengthen and humanize the contribution of science to the progress of mankind.

G. Lapage

A KINETIC THEORY OF LIQUIDS

By Prof. MAX BORN, F.R.S., and H. S. GREEN
University of Edinburgh

THE problem of formulating a rigorous mathematical description of the molecular motion in liquids has always been regarded as much more difficult than that of the kinetic theory of gases or of solids, because one has the simplifying features of low density in the case of gases, and of a regular lattice structure in the case of solids, while the molecules of a liquid are in a dense and disordered state. It is clear that only approximate solutions may be expected; but, in introducing the approximations, we think that the following principle should be accepted. The general equations should be established as rigorously as the present knowledge of the fundamental law permits; the solution of these equations may, however, be obtained by approximations suited to the case.

What is now the situation in the theory of liquids? It is true that a number of attempts have been made to solve special problems with the aid of devices appropriate to each particular purpose; these have been admirably summarized in a recently published text-book by Frenkel[1]. In the special case of equilibrium one has even a rigorous formulation of the general equations, namely, that obtained by applying the methods of statistical mechanics. If, here, the results are meagre, and no comprehensive equation of state is available, this is only because of the formidable mathematical difficulties in reducing and interpreting the formal solutions. It is quite different with the theory of liquids in motion; here no serious attempt to derive the dynamical and thermal equations from the point of view of atomistic theory is known to us[*]. Enskog[2] in his later work tried to derive a generalization of Boltzmann's equation which would apply to liquids; but owing to a wrong approach, the equation he obtained was still not quite correctly formulated, and contained besides an unknown function which he had no means of determining.

Yet all the fundamental conceptions and laws required for the purpose are known; in the domain of higher temperatures, we have Newton's laws of motion and the principles of statistics and probability, and for lower temperatures, their quantum analogues. The reason why this problem has never been properly tackled seems to lie in the fact that hitherto the engineers have been satisfied with ordinary hydro- and thermo-dynamics, and have had no need of an atomistic sub-structure, while the physicists, interested in atoms and the elementary particles (protons, neutrons, electrons, etc.), have preferred to study gases, where the atoms are almost isolated, or solids, where they act in harmony. However, the situation has changed during the last few years. On one hand, regularities in the values of the molar constants, like the coefficients of viscosity, diffusion and thermal diffusion, have been found, which need atomistic explanation. On the other hand, in low-temperature physics, atomistic and molar behaviour can no longer be separated. In particular, the phenomenon of superfluidity in liquid helium II defies classical hydrodynamics; it is a quantum effect of matter in bulk. All attempts to explain the apparent disappearance of viscosity below the λ-point of helium seem to be futile so long as the mechanism of viscosity in liquids is not known even for ordinary temperatures.

These were the motives which led us to formulate a general kinetic theory of dense matter. It will be published in complete mathematical detail in the *Proceedings of the Royal Society*; but as a period of time will elapse before the later papers of the series will appear, we shall give here a short account of our methods and results.

Comparing the kinetic theory of gases (which applies to dilute systems in equilibrium and in motion) with general statistical mechanics (which holds for any system in equilibrium only), one sees that in the first case a distribution function $f_1(t, x^{(1)}, \xi^{(1)})$ is used which depends on the time t, and the position vector $x^{(1)}$ and the velocity vector $\xi^{(1)}$ of a single molecule, while in the second case one has a distribution function $f_N(x^{(1)}, x^{(2)}, \ldots, x^{(N)}, \xi^{(1)}, \xi^{(2)}, \ldots \xi^{(N)})$ which depends not on time, but on the position and velocity vectors of all N particles of the system. These are obviously two extreme cases of a set of functions

$$f_1(t, x^{(1)}, \xi^{(1)}), f_2(t, x^{(1)}, x^{(2)}, \xi^{(1)}, \xi^{(2)},) \ldots, \quad f_N(t, x^{(1)}, x^{(2)}, \ldots, x^{(N)}, \xi^{(1)}, \xi^{(2)}, \ldots, \xi^{(N)}) \qquad (1)$$

where each function depends on the co-ordinates and velocities of a number of particles, indicated by the superscripts (1), (2), (3), ..., and time. Our first step consists of introducing this whole set of functions (1), which we call 'multiple distribution functions'.

The function $f_h(t, x^{(1)}, \ldots, x^{(h)}, \xi^{(1)}, \ldots, \xi^{(h)})$, multiplied by the product of the elements of space and velocity around each of the points, measures the probability of finding each of the volume elements occupied by molecules with velocities in the given velocity range. Now, the main feature of a dense assembly of particles is that the distribution function of order h is *not* a product of those of lower order; for example, $f_2(t, x^{(1)}, x^{(2)}, \xi^{(1)}, \xi^{(2)})$ is not equal to $f_1(t, x^{(1)}, \xi^{(1)}) f_1(t, x^{(2)}, \xi^{(2)})$. There are, however, obvious relations between consecutive functions; for example, by integrating f_{h+1} over the range of coordinates and velocities of the last particle, one obtains f_h, apart from a normalizing factor $(N - h)$.

We need also to generalize the conception of distribution function by taking as arguments for each molecule, not only the position and velocity vectors, but also the acceleration vectors $\eta^{(i)}$; these functions we write $g_h(t, x^{(1)}, \ldots, x^{(h)}, \xi^{(1)}, \ldots, \xi^{(h)}, \eta^{(1)}, \ldots, \eta^{(h)})$. If g_h is integrated over the ranges of the $\eta^{(i)}$, one obtains f_h, and if f_h is integrated over the $\xi^{(i)}$, one obtains the number density functions n_h, which depend only on the position vectors $x^{(1)}, \ldots, x^{(h)}$, and time. The condition that a group of h molecules preserves its identity in the course of the motion is a kind of multi-dimensional continuity equation for each of the functions n_h, f_h, g_h. The most important of these is the equation for f_h, which has the form

$$\frac{\partial f_h}{\partial t} + \sum_{i=1}^{h} \frac{\partial f_h}{\partial x^{(i)}} \cdot \xi^{(i)} + \sum_{i=1}^{h} \frac{\partial}{\partial \xi^{(i)}} \cdot (f_h \overline{\eta^{(i)}}) = 0. \qquad (2)$$

Here $\overline{\eta^{(i)}}$ is the mean acceleration of the molecule (i) obtained by averaging $\eta^{(i)}$ with the help of the distribution function g_h.

Now the main point of the theory is reached: this mean acceleration can be expressed in an alternative way, with the help of Newton's equations of motion.

---

[*] (*Note added in proof.*) We are indebted to Prof. E. N. da C. Andrade for directing our attention to an important paper recently published by J. G. Kirkwood (*J. Chem. Phys.*, **14**, 180; 1946), in which he approaches our problem from the point of view of statistical mechanics and the Brownian movement, and succeeds in deriving our equation (2). In the work so far published, he does not, however, appear to have developed this equation to any great extent.

These give the acceleration of one molecule in terms of the forces due to all the others. The resultant force may be regarded as due to two actions: first, that of the remaining $h - 1$ particles of the group, and secondly, that of all the rest. As the configuration of the h particles is known, the averaging of the force must be performed only over the other; this is effected by integrating over all configurations of a single particle in an arbitrary position, supplied with the weight f_{h+1}/f_h. Hence $\overline{\eta^{(i)}}$ can be expressed in terms of an integral containing f_{h+1} in the integrand, and when this is substituted into (2) one obtains an integro-differential equation connecting two consecutive functions f_h and f_{h+1}.

The result is a chain of N integro-differential equations for the set of functions $f_1, f_2, \ldots, f_N$, which formulate the statistical laws of motion in a rigorous way. Each equation has the form (2), and contains one 'statistical term' involving, through $\overline{\eta^{(i)}}$, the following function f_{h+1}. The first task of a new theory is to show that it contains well-established special cases. We therefore require to prove that the Maxwell–Boltzmann kinetic theory of gases is a limiting case. This is effected by assuming the density to be so low that only binary encounters between the molecules need be taken into account, so that the function f_2 is, for large distances between the particles ($|x^{(2)}-x^{(1)}|$ large), a product $f_1(t, x^{(1)}, \xi^{(1)})$ $f_1(t, x^{(2)}, \xi^{(2)})$. Then the statistical term in (2) can, for $h = 1$, be transformed exactly into the 'collision integral' well known from the kinetic theory of gases, and the equation becomes identical with Boltzmann's integro-differential equation, from which all the thermo-mechanical properties of gases can be derived (*cf.* Chapman and Cowling[3]).

The second limiting case is that of equilibrium, where the new theory ought to be identical with statistical mechanics. It is easy to show that, if Gibbs's canonical distribution function is taken for f_N, and $f_{N-1}, f_{N-2}, \ldots, f_2, f_1$ are derived from it by integration, all our equations are satisfied. The proof rests essentially on the fact that no function f_{N+1} exists; hence the equation (2) has no statistical term for $h = N$. One can prove much more, however, namely, that under reasonable conditions, any configuration approaches the equilibrium distribution, so that the statistical motion is an irreversible process. The proof is very similar to the corresponding one in the kinetic theory of gases; it uses the notion of the H-function (negative entropy) defined in a way suggested by ordinary statistical mechanics. The validity of the H-theorem depends on a proper choice of the conditions under which the system is considered. If one assumes the system to be closed and completely independent of the outer world, no irreversibility can be expected. The last equation would then contain no statistical term, and as all of $f_{N-1}, f_{N-2}, \ldots, f_2, f_1$ can be expressed in terms of f_N, the solution would have no statistical character. One has to assume that the system of N particles is in thermal contact with a bigger one, which can be assumed to consist of the same kind of particles; this introduces in the Nth equation a statistical term containing f_{N+1}. Then the original system of N particles satisfies the H-theorem. In this way the new theory proves to be completely self-contained; it does not rely on results known from statistical mechanics, but contains this theory as a special case.

Although one would scarcely expect new results in this special case of equilibrium, we have investigated it again with our new methods, and find that these lead to new approaches to the intractable integrals of statistical mechanics. Our main general result is that all thermodynamical properties of the system can be expressed in terms of the function n_2 alone, which expresses the probability of finding two particles at given positions $x^{(1)}$, $x^{(2)}$. In the equilibrium of fluids, it depends obviously only on their distance r, and is identical with the radial distribution function determined in experimental investigations on the scattering of X-rays by monatomic liquids. Moreover, all thermodynamical quantities can be expressed in terms of the Fourier transform of $n_2(r)$, which is directly given by the intensity distribution of the scattered X-rays. Hence the thermodynamics of a liquid are reduced to the knowledge of this experimental function. The rigorous theoretical treatment leads to the well-known formidable difficulties in evaluating the partition function of statistical mechanics; the new formulation, however, suggests a different approach, which, though only approximate, can be easily improved. As we have pointed out, the second distribution function, depending on two particles, is not a product of two functions, each depending on one of the two particles. For example, $n_2(x^{(1)}, x^{(2)})$ differs from the product of $n_1(x^{(1)})$ and $n_1(x^{(2)})$ (which in equilibrium are both constant and equal). In the same way, the equation

$$n_1{}^3\, n_3\,(x_1, x_2, x_3) = n_2\,(x^{(2)}, x^{(3)})\; n_2\,(x^{(3)}, x^{(1)})\, n_2\,(x^{(1)}, x^{(2)}) \tag{3}$$

will not hold exactly, but will be a much better approximation to the real situation than $n_2(x^{(1)}, x^{(2)}) = \text{const.}$ If this equation (3) is not sufficiently accurate, one can use it as a first approximation and then assume a similar expansion for n_4 in terms of n_3, and so on.

In fact, Kirkwood[4] has shown that (3) leads to reasonable results; so we have accepted it and called it the 'Kirkwood' approximation. With its help, f_3 can be eliminated from the statistical term in the second equation (2), which together with the first then forms a closed system for the determination of f_1 and f_2. They can easily be reduced to a single integral equation for $n_2\,(r)$; it is a generalization for arbitrary central forces of an equation already established and solved by Kirkwood for 'rigid spherical molecules'.

We have succeeded in solving our equation for the general case, and find that at low temperatures there exist solutions which indicate an almost periodic behaviour of n_2; we believe that these correspond to the solid state (lattice structure). A Russian physicist, Vlasov[5], has published some papers in which he tries to derive the existence of crystal lattices from a Maxwell–Boltzmann equation in which the mutual forces of the particles are introduced, but the statistical term completely neglected. Although it seems to us that this attempt was not entirely successful, we believe that Vlasov's idea will prove correct.

Other solutions of the integral equation for $n_2(r)$ which for large r tend to the constant $n_1{}^2$ correspond to the liquid state. They have the well-known features of the radial distribution function in liquids: a set of density maxima the amplitudes of which rapidly decrease with r.

The $n_2(r)$ thus found can be used to obtain expressions for the free energy, from which all thermodynamical quantities can be derived. For low densities (gas), the pressure can be expanded in a series of powers of the density

$$p = \sum_{k=1}^{\infty} \beta_k n_1{}^k, \tag{4}$$

where the coefficients, the so-called virial coefficients, are functions of the temperature. Mayer[6] has succeeded, by a rigorous combinatory method, in finding expressions for the β_k in terms of integrals involving the potential energy $\varphi(r)$; but only the first few of these 'cluster integrals' could be evaluated, even for simple force laws. Our method produces for the β_k simple definite integrals which are much more tractable. Mayer has shown that the power series (4) ceases to converge at a definite density for each temperature, which he has associated with the point of condensation. But neither his work nor that of others (Born and Fuchs[7], Kahn[8], etc.) has succeeded in elucidating the character of the singularity or penetrating beyond it into the liquid region. Kahn has given an expression for the analytic continuation of the power series (4) into the region beyond the circle of convergence, but has misinterpreted his results. He accepts the well-known p–v diagram in which an isotherm is usually drawn with a horizontal part (p = const.) connecting the branches which represent the vapour and the liquid, and he endeavours to show that Mayer's method leads rigorously to such a region p = const., representing the process of condensation. In fact, this graphical representation of condensation by a line has no significance; the correct formulation is, that for a certain domain of pressure and temperature, the equation of state has two solutions v_1, v_2, for the specific volume, corresponding to stable states in equilibrium, vapour and liquid. The expression for p found by Kahn which he considers to be constant is, in fact, a function of volume; his error is due to his assumption that all the virial coefficients β_k are constant, whereas they depend on the volume more and more as k approaches the number of molecules in the liquid. Kahn's expression for p is the equation of state for the liquid, though in a quite untractable form.

Our theory shows that the liquid differs from the gas by the existence of real roots of a certain transcendental equation, revealing at once the analytical character of Mayer's singularity as a branch point, and allowing the derivation of an explicit equation of state in terms of the complex root of the same transcendental equation. The formulæ obtained are quite manageable; a numerical discussion is in progress.

The main object of our investigation is, of course, the derivation of the thermo-mechanical equations of motion and a determination of the coefficients of viscosity, thermal conductivity, etc., in terms of the atomic interaction. A new feature of this theory is that one obtains not only the ordinary equations of hydrodynamics (including the equation of the flow of heat), but also generalized ones describing simultaneously the motion of groups of molecules. In these there appear the mean number densities n_1, n_2, ..., n_h, the corresponding mean velocity vectors, $u_1{}^{(i)}$ $u_2{}^{(i)}$, ..., $u_h{}^{(i)}$, and the mean kinetic energies or 'temperatures' $T_1{}^{(i)}$, $T_2{}^{(i)}$, ..., $T_h{}^{(i)}$. The latter concept is of particular interest. These molar equations are solvability conditions of a kind for the integro-differential equations for the distribution functions f_h. The equations for f_h have a great many solutions which have no significance for our purpose (describing, for example, such configurations, where one particle is shot through the rest with an exceedingly high velocity, as may happen in radioactive processes). We have, therefore, singled out for study those 'normal' solutions, corresponding to ordinary hydrodynamics, where the state of the system is completely determined by the values of n_1, u_1 and T_1 for one particle, throughout the fluid. It appeared that the classical method developed by Hilbert[9], Enskog[10], and Chapman[11] in the kinetic theory of gases (virtually equivalent to an expansion in inverse powers of the mean free path) was useless for liquids, because there the free path becomes vanishingly short, and the mutual exchange of potential energy between the molecules correspondingly large. We therefore developed a new method of expansion in powers of the space gradients of the density, mean velocity, and temperature.

The result is, that all properties of a liquid in motion are, just as in the case of equilibrium, compounded of two parts, due to the thermal motion and the intermolecular forces respectively. The first, which is the only one considered in the theory of gases, is quite insignificant in liquids; when it is neglected, one obtains the coefficients of viscosity and thermal conduction as integrals involving the radial distribution function and its distortion by the motion.

The actual determination of this distortion is rather complicated, but one can obtain practical results without actually solving the appropriate integral equation. For it is evident that n_2 will have the form $n_2{}^0(1+\alpha)$, where $n_2{}^0$ is the equilibrium function, and α a correction due to the motion; the dependence of α on temperature and density can be determined by a simple dimensional consideration. The resulting integral can be evaluated by the method of steepest descent, as soon as the potential energy $\varphi(r)$ between two molecules is known. To give a concrete example, let us choose a function of the kind proposed by Lennard-Jones[12], $\varphi(r) = -ar^{-6} + b/r^{-12}$, the first term corresponding to the van der Waals attraction in the form obtained by London[13]. Then one obtains for the coefficient of viscosity

$$\mu = c\left(\frac{r_0}{r_1}\right)^5 \frac{m\nu_0}{r_0} \exp - \varphi(r_1)/kT. \tag{5}$$

Here c is a numerical constant, r_0 the equilibrium distance of two particles (diatomic molecule), given by $\varphi'(r_0)=0$, r_1 the actual mean distance of neighbouring particles, and $\nu_0 = \{\varphi''(r_0)/4\pi^2 m\}^{\frac{1}{2}}$ the frequency for the diatomic molecule.

One may compare (5) with the empirical formulæ of the type mentioned by de Guzman[14], and first established and studied in detail by Andrade[15]. At the melting point, Andrade's formula reads $\mu \sim \frac{m\nu_1}{r_1}$, where ν_1 is the frequency determining the specific heat, which may be taken, for example, from *Reststrahlen* results or put in terms of Lindemann's formula. One recognizes this factor in our formula (5), but with constant r_0 and ν_0 referring to the diatomic molecule. However, our formula depends on the volume in a different way from Andrade's, namely, by the factor

$$\left(\frac{r_0}{r_1}\right)^5 = \left(\frac{v_0}{v_1}\right)^{5/3}.$$

In fact, Andrade's ingenious derivation is based on a simplified physical picture which by its nature must fail to give dimensionless factors $\left(\text{powers of } \frac{v_0}{v_1}\right)$. Also Andrade finds the exponential factor, but gives no theoretical explanation except that it must be a kind of activation and, therefore, have the form of a Boltzmann factor.

A different formula for the coefficient of viscosity has been given by Fürth[16]. It is based on his theory of 'holes'; the liquid is regarded as a continuum of small bubbles, the size and apparent mass of which depend on the surface tension. These bubbles perform a kind of Brownian movement, and transfer energy and momentum; the coefficient of viscosity can thereby be expressed in terms of the surface tension. Fürth's formula contains an exponential factor of the same type as ours; the remaining factor cannot be compared with ours because of the entirely different assumptions made. But Fürth has shown that his formula is practically identical with Andrade's because of some empirical relations between the constants involved; and similar considerations can be applied by comparing Fürth's formula, or that of Ewell and Eyring[17], with our own.

Our theory also provides an account of the variation of the apparent viscosity of liquids under the action of external forces, such as electric and magnetic fields. One general conclusion here is that the field cannot by itself produce any change in the apparent viscosity if it can be derived from a scalar potential; this appears to be in accord with the recently published experimental work of Andrade and Dodd[18]. On the subject of conducting liquids and the effect of alternating fields, which they have also studied, we have not yet reached any definite conclusion; this remains a subject for further study.

We hope to generalize the theory also in the following different directions. The first and most obvious step is the introduction of internal degrees of freedom of the molecules; this is probably closely connected with giving up the assumption of central forces. Then mixtures of two or more kinds of molecules have to be considered in order to obtain the laws of ordinary and thermal diffusion; the latter (Soret effect) will be of special interest, as no theory for liquids seems to exist (see the dissertation by de Groot[19], Chap. 5). Also our theory gives, as we have mentioned before, clear indications of the appearance of the solid state; we hope that it will lead to a better understanding of the present lattice dynamics and its limits, in particular to theories of melting and plasticity.

The most important generalization envisaged is the introduction of quantum mechanics. For there are known several examples of quantum 'liquids': helium II (superfluidity), the substance of nuclei (droplet model), and perhaps also electrons in metals (superconductivity). It is, of course, hopeless to try to understand the abnormal viscosity in liquid helium if one has no theory of viscosity in normal liquids; this gap has now been closed, and we plan to extend our theory of viscosity to quantum liquids.

ORIGIN OF ERYTHROCYTES

By Dr. S. H. WAJDA
Department of Anatomy, University of Birmingham

CONVENTIONAL views on hæmopoiesis may be said to be well founded, in spite of the fact that beliefs in the transformation of precursor elements to definitive blood cells, through a series of specific cell stages, represent, so far as the adult mammal is concerned, dynamic concepts based upon more or less discontinuous observations—in the sense that no one has observed, either *in vitro* or otherwise, the whole process of transformation in adult tissue. Because of this it is not surprising that the facts have been interpreted differently at different times, and that more than one view has been advanced about the development of the blood elements. Equally, it is not surprising that commonly expressed views fail to account for all the known facts. The observations that are reported in this note fall so far outside current generalizations that they seem to lend themselves to a complementary hypothesis of blood formation.

If striated mammalian muscle that has been subjected to trauma is immediately fixed, cytological examination sometimes reveals the presence of very numerous cell elements that appear to constitute a continuous series of transition forms between muscle cells and granulocytes (in the rat, eosinophils in particular). As this observation could be taken to imply that muscle cells were being immediately transformed into leucocytes, as has been described by v. Möllendorff[1] and his school[2] in the case of fibroblasts, a series of experiments was undertaken, in which muscle was first excised and the injury inflicted *ex situ*, in a place chosen arbitrarily. These appear to show that extensive leucocytosis, accompanied by great numbers of transition forms, may occur in a muscle after its removal from the body. The circumstances obviously exclude the possibility of migration of leucocytes from the blood vessels, and also appear to preclude their origin from connective tissue cells, since cytological study of what seem the earliest transition forms suggests much more their derivation from muscle cells. The breakdown of the cellular muscular network results in the appearance of free cellular elements; and nuclear secretion appears to be the main factor responsible for the production of leucocyte granules. The process is so rapid that it has more the character of a cell-catastrophe than that of a slow transformation. The possibility of such a change is implied in Maximow's[3] final paper, where it is stated that, in areolar tissue, the transition forms ('Lochkerne') appear only very rarely in specimens in which the possibility of injury during preparation has been minimized so far as possible. This observation obviously implies that rougher treatment stimulates their instantaneous appearance.

Intense secretory activity is not confined to the muscle nuclei of injured muscle. It is a constant finding in a working and anoxic muscle, although in this case it leads not to the production of granules, but to significant changes in the muscle-columns adjacent to the active nuclei. Thus whereas in the resting muscle the sarcomeres are neatly levelled, in activated muscle-columns the nonius-periods appear, and this in places results in a complete release of sarcomeres. This process is always accompanied by

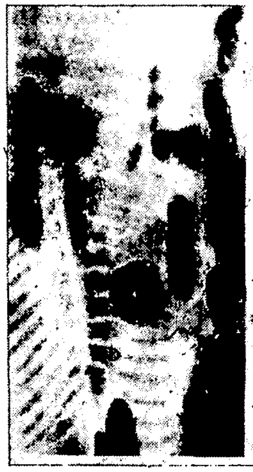

FIG. 1. WORKING MUSCLE (RAT). RELEASE OF SARCOMERES; THOSE LOWER DOWN HAVE THE APPEARANCE OF ERYTHROCYTES

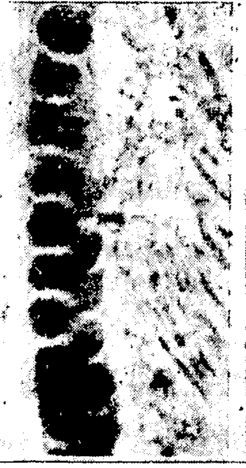

FIG. 2. ISCHÆMIA OF SHORT DURATION (RABBIT). APPARENT ABORTIVE ERYTHROPOIESIS RESULTING FROM THE TRANSFORMATION OF TWO MUSCLE-COLUMNS

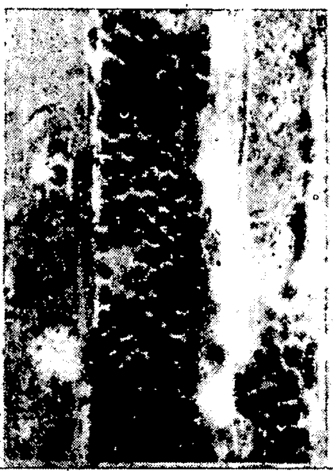

FIG. 3. MUSCLE DEGENERATION AFTER 5 DAYS (INJURY: FREEZING). APPARENT TRANSFORMATION OF THE WHOLE MUSCLE FIBRE

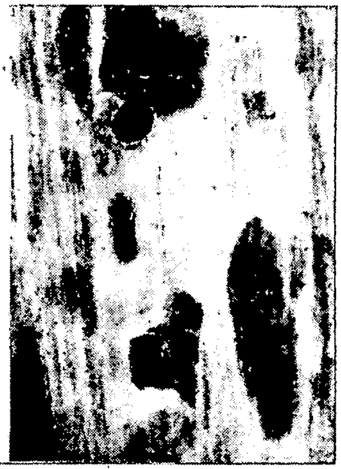

FIG. 4. WORKING MUSCLE (FROG). ABOVE: APPARENT ORIGIN OF FIVE THROMBOCYTES. BELOW: BUDDING OFF OF AN ERYTHROCYTE NUCLEUS

a striking change in the staining reaction of the sarcomere (best followed in Mallory stained sections), and by a marked increase of their refraction index (Fig. 1). The *A* disks of these sarcomeres, even before release, have a brilliant orange (eosin) or red (Mallory) coloration, contrasting with the pale colour of the alternating *I* disks. These observations can be related to the early findings of Bowman[4] (Bowman's disks) and to those of Thoma[5], who found that in certain conditions "the discoidal disintegration begins suddenly in an almost explosive manner". Reconstruction-models reproduced by Aurell and Wohlfart[6] provide useful information about the disposition of sarcomeres in the striated muscle, and the varying appearances which can be observed (nonius-periods, helicoidal fibres, staircase effect, sphenodes) would seem to constitute different stages in a process of sarcomere release.

The release and transformation of sarcomeres appear to be even more conspicuous in those forms of degeneration of striated muscle which are accompanied by hæmorrhage. The injury causing degeneration brings about a breakdown of the cellular network and a marked slowing down of the secretory process, while the nuclear secretion spreads more diffusely, and is not confined to discrete muscle-columns. As a result, a massive but abortive and stationary transformation appears to occur. In such cases (Figs. 2 and 3) the more or less freed sarcomeres are indistinguishable from erythrocytes. At the same time, isolated and secreting muscle cells appear to undergo an immediate transformation into lymphocytes. Rous[7] has shown that the number of lymphocytes delivered through the thoracic duct is increased fourfold as a prompt result of muscular activity. He concluded that "the variations caused by muscular exertion . . . are so pronounced as to suggest that the total number of lymphocytes in circulation must be considerably influenced by them. Clinical findings of other observers indicate that this is true. . . ."

All these cytological observations seem to call for a different, or at least an additional, approach to the problem of mammalian hæmopoiesis. Although it is recognized that in the early embryo red blood cells differentiate from primitive mesenchyme, their formation in later stages and in the mammal after birth is assumed to follow a series of fixed stages in their derivation from a nucleated cell in the red marrow. The basis of this genealogy is admittedly incomplete, and in part derives from a study of frank pathological conditions. One of its major difficulties is to explain the fate of the nucleus of the normoblast, in spite of the fact that its lysis (or extrusion) should be an extremely common occurrence.

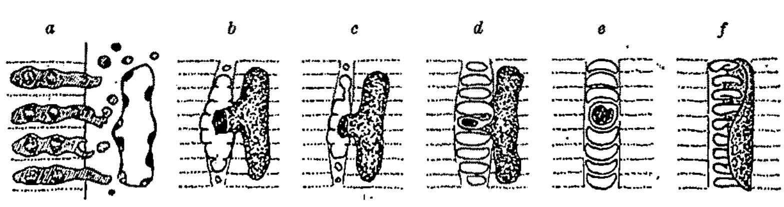

FIG. 5. COMPARATIVE ANATOMY OF ERYTHROPOIESIS (TENTATIVE SCHEME)

a Insects (redrawn from Holmgren[14]): trophospongial connexions between the muscle nucleus and sarcosomes.
b Frog: erythropoiesis (from observation *in vivo*); cf. Fig. 4.
c Frog: thrombocytopoiesis (from observation *in vivo*).

e Mammal: lymphocytic hæmal unit \ homologous to the amphibian erythrocyte (from
f Mammal: endothelial hæmal unit / photomicrographs).

Nevertheless, without prejudice to this conventional hypothesis, on which they do not touch directly, the observations that are summarized in this note suggest that there may be another source of red cells in the body—striated muscle. They seem to indicate, first, that mammalian red blood elements may be 'cell products (plastids) non-homologous with cells', as was suggested more than fifty years ago on completely different grounds by Minot[8], and second, that striated muscle, owing to its high and immediate requirements of oxygen, is a store of partly preformed 'erythroplasts', and that it constitutes an erythropoietic organ of the normal mammal. As the muscle cells involved in the process assume, as a rule, the role of capillary endothelium, on our hypothesis erythropoiesis in these conditions is always intravascular: the 'opening up' of the muscular capillaries proceeds *pari passu* with the production of erythroplasts in their lumina—that is to say, muscle-columns may become transformed into blood-cell-bearing capillaries. By way of contrast, the question whether erythropoiesis is extravascular or intravascular remains controversial in the framework of current theories.

The likelihood that leucocytes and histiocytes can also be derived from muscle cells can be related to the analogous transformations of fibroblasts, as described by v. Möllendorff *et al.*[1,2]. On the hypothesis advanced here, striated muscle differs from mesenchyme by its immediate erythropoietic capacity. In this connexion it should be noted that Chèvremont[9] has recently conclusively shown that embryonic muscle cells in tissue culture may become transformed into histiocytes.

On the basis of our own evidence, as well as on that of other workers, the production of leucocytes may be regarded as a by-product of erythropoietic and vasoformative activity. In the frame of the working hypothesis put forward here, leucocytes can be regarded as the cellular waste, in the strictly morphological sense, of these processes, resulting from a partial or abortive response to the erythropoietic stimulus (probably anoxia) of some muscular elements.

The steps in this cytologically based hypothesis are set out in Tables 1 and 2.

Table 2 includes a reference to the 'vasoformative cells' of Schafer[10] and Ranvier[11], who remarked on the intracellular formation of red plastids as early as 1873 and 1874 respectively. It is also suggested that a single mesenchyme cell, be it a fibroblast or a myoblast, responds to anoxia in one particular way only, and that the end-forms into which they are transformed do not change one into another. Further, it follows that the process of inflammation may be regarded as the erythropoietic and vasoformative effort, more or less successful, of anoxic tissue.

TABLE 1. HÆMOPOIESIS IN MUSCLE. POSSIBLE NORMAL COURSE OF EVENTS. CELLULAR NETWORK REMAINS CONTINUOUS. ERYTHROPOIESIS STRICTLY INTRAVASCULAR AND ADEQUATE. NO TISSUE ANOXIA DURING VASOFORMATIVE ACTIVITY. SCANTY CELLULAR WASTE IS QUICKLY REMOVED

Erythropoiesis		Vessel formation	Removal of waste	
Demands: limited	high	↓ ↓ ↓	Scanty waste deposited:	
Rapid production	Massive production		extra-vascular in:	intra-vascular in:
Endothelial cell	Lymphocyte	The accompanying waste furnishes the normal amount of white cells	Lymph nodes	During development: thymus; later: spleen (liver), *bone marrow*
↓ Erythroplasts	↓			

TABLE 2. HÆMOPOIESIS IN MUSCLE. INFLAMMATION. THE BREAKDOWN OF CELLULAR NETWORK. ERYTHROPOIESIS PARTLY EXTRAVASCULAR ('DIAPEDESIS') AND INADEQUATE, OFTEN MASSIVE BUT ABORTIVE (STASIS, THROMBOSIS). TISSUE ANOXIA ELICITS PARTIAL RESPONSE OF THE VESSEL-BUILDING CELLS (GRANULOPOIESIS, LATER HISTIOPOIESIS). CELLULAR WASTE INCREASED AND NOT REMOVED (SUPPURATION, NECROSIS)

Erythropoiesis				Vasoformative effort					No removal of waste			
Full and quick response	Full and massive response	Full but unsuccessful response of isolated elements	Full and successful response interrupted by tissue damage	Quick partial response	Quick abortive response	Slower partial response	Delayed erythropoietic response of isolated elements	Slow response	Vestigial formative activity	Slow negligible response	Vestigial erythropoietic response	Delayed and vestigial or no response
↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓
Endothelial cell + erythroplasts	'Lymphocyte + erythroplasts	Normoblasts	'Vasoformative cells'	Eosinophils	Polymorphonuclears	Basophils (mast cells)	'Erythrophages', Russell body cells, blood-pigment cells	Histiocytes	Epithelioid and giant cells	Polyblasts	Plasma cells, round cells	Myeloid elements
						Inflammation						
			acute					chronic				

A further study of surviving, as well as fixed and stained, frog muscle has shown that the nuclei of erythrocytes bud off from the muscle nuclei (Fig. 4), and suggest that the erythrocyte nuclei incorporate a number (6–8 ?) of sarcomeres into their cell body. This seems to explain the findings of Emmel[12] and others on the non-nucleated 'erythroplastids' of *Batrachoseps attenuatus* Esch., as well as the presence of bundles of myofibrils in amphibian erythrocytes, as has been recorded by Meves[13] and also by other workers.

Fig. 5 presents a scheme of a tentative comparison of erythropoiesis in vertebrates, and includes the phenomena described in the muscle of insects by Holmgren[14].

I wish to thank Prof. S. Zuckerman for advice and criticism in the presentation of this new working hypothesis.

BRITISH COMMONWEALTH SCIENTIFIC CO-OPERATION

THE Report of Proceedings of the British Commonwealth Scientific Official Conference, London, 1946*, in addition to the Recommendations and Resolutions of the Conference, includes the opening statements of the Lord President of the Council and of the chairman of the Conference, Sir Edward Appleton, as well as a brief historical review showing the sequence of the Conference to that held in 1936, and its relation to the Royal Society Empire Scientific Conference which immediately preceded the Official Conference, and the recommendations from which are appended to this report. The Official Conference, which met during July 9–19, had as its terms of reference "to consider the best means of ensuring the fullest possible collaboration between civil Government scientific organisations of the Commonwealth and to make formal recommendations for the approval of the Governments represented". Defence science was not considered, and the working of the Imperial Agricultural Bureaux was reviewed at a further conference during the following week. Arrangements for the Conference were entrusted in October 1945 to a Working Party of the Civil Science Panel under the chairmanship of Mr. O. F. Brown, while on the arrival of the delegates in London, the heads of oversea delegations, together with the secretaries of the Department of Scientific and Industrial Research, the Agricultural Research Council and the Medical Research Council and a representative of the Colonial Office, formed a steering committee with Sir Edward Appleton as chairman and Mr. O. F. Brown as secretary.

In his opening statement, Mr. Herbert Morrison, emphasizing that it was possible to pay too much attention to organisation, pointed out that throughout the British Commonwealth we shall be faced for some years to come with an acute shortage of scientific man-power. Accordingly, there is a risk that too elaborate organisation might result in absorbing into the administrative machine many trained scientific workers who are badly needed in research laboratories, in universities or similar institutions, in Government laboratories or in industry. Sir Edward Appleton, also referring to the importance of a proper balance between university research and research under Government auspices, said that in Great Britain we have tried to avoid the danger of static Government research institutions by budding off new establishments from existing ones as need arose. He recognized the importance of active attention to the maintenance of the scientific health and outlook of workers in the Civil Service. University conditions generally ensure the maintenance of the mental adventurousness and lively imagination so necessary for scientific progress, and Sir Edward Appleton stated that an Interdepartmental Scientific Panel, of which he is chairman, is now considering the implementation of the recommendations of the Barlow Report on scientific staff. He urged that official scientific workers should do all that they can, when necessary, to convince their Governments of the importance of the Royal Society's Scientific Conference proposals for extending facilities for independent fundamental research at universities throughout the Commonwealth, and he pointed out that the pension provision of the civil 'scientific officer' grades in the United Kingdom scientific service is in most Departments specially designed to facilitate the movement of workers. The Department of Scientific and Industrial Research in particular favours such transfers as encouraging both fundamental research at the universities and applied research in industry.

One session of the Conference was in fact devoted to the movement of scientific men. The subject was discussed under four heads: the general need for interchange; student interchange within the Commonwealth; interchange of scientific staffs within the Commonwealth; and movement of scientific workers to assist territories outside the Commonwealth. Resolutions were passed urging steps to promote the maximum general interchange and supporting the Royal Society's Conference recommendation for the central compilation, classification and publication of lists of post-graduate scholarships available for scientific study within the Commonwealth, a task which would be appropriate to the proposed British Commonwealth Scientific Office, and favouring the provision of further travelling fellowships for post-graduate work, in particular the establishment of research fellowships tenable by United Kingdom students in the Dominions and in India. Other recommendations urge the exploration by university authorities of the possibility of co-operation in the award of post-graduate degrees; the exemption from income tax of all travelling scholarships and travel grants, and adoption of a system of adequate financial provision for travelling and subsistence allowances to avoid undue financial burden on the individual in travelling abroad for the purposes of study; special concessions for scientific workers travelling abroad for study, for attendance at scientific conferences and for similar purposes. The recommendations of the Royal Society's Conference that staff complements should be raised to a level sufficient to offer individuals adequate time for research, for study, and for travel leave without, thereby, placing additional burdens on their colleagues, are supported. Standard conditions are suggested for the temporary transfer of scientific workers, and the report of a committee set up by the Conference to consider superannuation was adopted. This report recommends the adoption throughout the Conference of a scheme or schemes with superannuation benefits not less favourable than those of the Federated Superannuation System for Universities. This session also noted the increasing demands from territories outside the Commonwealth for expert scientific advice, and suggested that such requests should pass through a British Commonwealth Scientific Office, London, so that the resources of scientific man-power and of educational establishments in other parts of the Commonwealth as well as of the United Kingdom may be used to the best advantage.

The first session of the Conference was concerned with the question of scientific liaison offices in view of its bearing on many of the other problems before the Conference. Sir Edward Appleton referred to the success of the appointment of scientific liaison officers during the War, and the first resolution of the Conference endorsed the views expressed in a resolution from the Royal Society's Conference on the functions of liaison offices as an essential part of the machinery for facilitating interchange of scientific workers and related activities. The Conference warmly welcomed the proposals for setting up a liaison office in London in which the several scientific liaison offices of the various parts of the Commonwealth would be housed under one roof, and certain common services such as library and records, typewriting, photographic services, microfilming, and photostating would be pooled, and invited the Governments concerned to proceed with the necessary arrangements as soon as possible. The Conference also regarded the British Commonwealth Scientific Office in Washington as a valuable and necessary element in the permanent machinery for scientific liaison, but recommended a change of name to "British Commonwealth Scientific Office, North America". A committee set up by the Conference, under Dr. E. Marsden as chairman, formulated detailed proposals regarding accommodation and common services, administration and finance for the London and Washington Offices to be subject to review in three years time, which were later adopted by the Conference.

---

* British Commonwealth Scientific Official Conference, London, 1946. Report of Proceedings. Pp. 73. (London: H.M. Stationery Office, 1946.) 1s. 3*d*. net.

The next session, considering collaborative research and specialist conferences, at which Sir David Rivett presided, adopted a resolution recognizing the need for a standing committee which would be responsible for the arrangements for specialist conferences, in co-operation with appropriate Commonwealth or international bodies. It was recognized that, whereas there are subjects in which the work can be left to develop along its own lines, the workers merely requiring to be aware of what is going on in their fields in other parts of the Commonwealth, to be able to exchange information quickly and to be acquainted with progress in the development of new techniques and results, in other subjects a concerted attack is necessary. At its opening session the Conference had appointed committees on the agricultural sciences, medical sciences, and oceanography and fisheries to consider questions of collaborative research, and to these committees this session now referred a number of recommendations from the Royal Society's Conference.

To the Medical Science's Committee there were thus referred the recommendations on the physiological and psychological factors affecting human life under tropical conditions and in industry; the etiology and control of infectious and transmissible diseases; and on measures for dealing with the special nutritional problems of the British Empire, including the nutritional status of the indigenous peoples of the Colonies. In addition, the Conference referred to this Committee two recommendations: (1) that the attention of Governments of the Commonwealth in countries where malaria is prevalent should be directed to the urgent need of integrating fish-culture practice with measures for malaria control; and (2) that in view of the steady increase in the demand for insulin, all countries of the Commonwealth should make every effort to collect, process and preserve all available pancreas. The report of this Committee, which was adopted by the Conference, recommended that in each Dominion there should be a body sponsored by the Government and responsible for stimulating, supporting and organising medical research, and that each Dominion organisation should establish an effective liaison with the others so as to provide machinery for the discussion on strategy of research on problems of wide mutual interest, for calling specialist conferences when required, and for the movement of scientific workers between different parts of the Commonwealth. In endorsing the recommendations referred to it, this Committee urged the necessity for developing at all levels of Dominion and Colonial government a proper awareness of the nutritional needs of the indigenous peoples and also the need for more food technologists.

The Agricultural Sciences Committee recommended that the standing committee should examine the feasibility of calling at an early date a joint conference of specialists to explore the problems concerned with the integration of the three main branches of agricultural science. Of the subjects of the specific recommendations of the Royal Society's Conference referred to the Committee, soil conservation and land utilization, the maintenance of soil fertility with special reference to the role of soil organic matter, soil deficiencies in relation to plant and animal nutrition, the ecology of plants and animals of agricultural importance, and grassland and pasture research were suggested as suitable for discussion at such a conference. The control of vegetation by chemical means, insecticides and fungicides, pests in stored products, methods of collection and statistical analysis of data relating to agriculture, and biological control of insects and weeds are subjects recommended for inclusion in future specialist conferences.

The Committee was greatly impressed by the need for securing more adequate meteorological data as a basis for climatic studies, and the subject was considered by a sub-committee, which recommended the establishment at representative centres of meteorological stations equipped to measure the factors of moisture, light and temperature affecting biological activity; and indicated specific needs to be met. The equipment of biological field research stations was also recommended. The full Committee also recommended that the attention of Governments be directed to the need for preliminary surveys of the extent of utilization and of wastage of agricultural products in their individual territories as a basis for research, and to the importance of preserving native breeds of farm stock to serve as a source of breeding material, and of defining the structural and functional characteristics of such breeds. Further subjects recommended for reference to other committees or conferences included the provision of improved facilities for collecting living plant materials and for maintaining varietal collections of economic species; the extension of taxonomic and other biological research at museums and botanic gardens; and the utilization of aerial survey methods for studying and estimating crop areas and for detecting locust swarms. Various problems of plant physiology, genetics and pathology, and of the physiology of domesticated animals, suggested by the Royal Society's Conference for further research, were recommended for bringing before the notice of the appropriate government and university authorities.

The Oceanography and Fisheries Committee endorsed the various recommendations of the Royal Society's Conference referred to it and recommended particular attention to long-term research, in which regional co-operation should be an aim. The establishment of wave-recording stations to permit collaborative investigations of sea and swell conditions was also recommended, and the Committee stressed the need for the dissemination of information on oceanography, limnology, fisheries research and technology, especially to isolated research workers. The establishment of a journal for Colonial fisheries and oceanography would be welcomed.

Other committees were set up to consider radio and cosmic ray research; the establishment of a Commonwealth collection of type cultures; mineral resources and geology; building research; fuel research; food preservation; and regional research in Africa. Reports with recommendations from all these committees, which are detailed in the report, were considered at the 'review sessions', and the Conference also endorsed the recommendations of the Royal Society's Conference on modern methods of mapping and exploration by air.

Discussion at the session of the Conference devoted to aspects of collaboration in research between Government and industry centred mainly around the question of research associations. Concerning the publication of results, it was emphasized that practically all results of scientific work are published as papers before societies or printed in scientific periodicals. The Conference adopted a resolution noting with satisfaction the growth of the research association movement within the Commonwealth, and recommending no departure from the present practice whereby Government departments, research institutions or firms in Commonwealth countries, wishing to participate in the benefits of membership in a particular research association in another Commonwealth country, negotiate on a mutually satisfactory basis for membership with the Association concerned.

At the session on information services, the Conference adopted a resolution endorsing the general recommendation of the Royal Society's Conference regarding a conference on abstracting and information services, but recording the view that such a discussion should be regarded as preliminary to a wider conference to which the United States, as well as operating agencies of the United Nations concerned with the subject, should be invited. It was also recommended that the suggested British Commonwealth Scientific Office in London should organise machinery for ensuring that there is within each co-operating country a list of translations of scientific papers, made or contemplated throughout the Commonwealth, in languages other than English. A committee appointed to consider proposals for alteration in the organisation and functions of the Imperial Institute recommended the adoption, in general, of the suggestions of the Skelton Committee of the Imperial Committee on Economic Consultation and Co-operation, 1933, but suggested the establishment of two separate organisations for dealing with mineral resources and with plant and animal products respectively.

The session dealing with the utilization of the results of research adopted three resolutions. First, as regards information on methods for promoting the utilization of non-patentable scientific and technical results which have been found successful, the Conference desires the appointment of an editor, attached to the British Commonwealth Scientific Office in London, to collect this information and prepare a report for circulation by December 1947. The second resolution recommends the establishment of close co-operation between any organisations established locally to ensure the maximum utilization in the national interest of patentable discoveries, in order that there may be the greatest possible use of patentable discoveries throughout the Commonwealth and Empire. Finally, it was agreed that a practical scheme for a Commonwealth patent would have substantial advantages for technical development in the Commonwealth, but it was realized that technical difficulties may well render such a scheme impracticable; the Conference, therefore, recommended that heads of delegations should discuss with their Governments the desirability of re-examining the whole question.

At the final review session, the Conference adopted resolutions to provide permanent machinery for facilitating scientific collaboration in the Commonwealth and for following up the recommendations of the Conference by establishing a standing committee, with a secretary and 'working party' in London. The standing committee consists of the executive heads of Government organisations for scientific and industrial, agricultural and medical research in the United Kingdom, the Dominions and India, together with three scientific representatives nominated by the Colonial Office. The 'working party' consists of deputies of members of the standing committee with its secretary as chairman, and the overseas members of the standing committee have already indicated that their deputies will be their liaison officers serving in London.

OBITUARIES

Prof. Karl Mannheim

It is quite impossible to estimate the loss which education and scholarship have suffered as the result of the untimely death on January 9 of Karl Mannheim at the early age of fifty-three. Though we have had him with us in Britain for barely fourteen years, his work and influence among us afford a signal example of the gain that accrues to this country from the welcome which, by tradition, it gives to refugee thinkers and scholars. A Hungarian by birth, he held the chair of sociology at the University of Frankfurt when the Nazis came to power. A marked man, he was removed from his post and took refuge in Britain. Here the London School of Economics generously made a place for him.

Distinguished as he was as a sociologist, his deepest concern was for education. To it, guided by well-grounded principle and proceeding in conditions of spiritual and intellectual freedom, he looked as a main instrument for the reconstruction which he knew that Western culture would have to undergo. He spoke often of what he called the 'Middle Way' or the 'Third Way', the *via media* between *laisser-faire* and totalitarianism. It was his conviction that Britain had the mission of demonstrating to the world how that way could be marked out and followed.

Wholly sympathetic to the English spirit, and coming in the fullness of his powers to assimilate and share in it, Mannheim was able to note elements of strength and weakness which were likely to be less apparent to the native-born. It was that, more than anything else, which made his personal influence so immensely valuable. So he was at his best in a seminar, or particularly in a discussion group with intimate friends. Then one saw how the humility and the profound humanity of the man were the sources from which arose the quick understanding, the intuitive sympathy and the infinite teachableness which were so characteristic of him.

In his teaching as in his works ("Ideology and Utopia", "Man and Society in an Age of Reconstruction", and "Diagnosis of our Time"), he claimed to be attempting no more than diagnosis. What he had of prescription was still for him in the region of fundamental hope and faith, rather than in that of a worked-out programme. Perhaps the latter part of his "Man and Society" could be taken as his formulation of the problem of our time—planning for freedom. As a further contribution to the co-operative study of the crowding problems, he planned the series of monographs which have been appearing in the International Library of Sociology and Social Reconstruction. Under his general editorship, some forty volumes have already appeared, and others are in preparation or projected.

But great and far-reaching as Mannheim's work and influence as a sociologist have been, it is as a teacher that his memory will be most deeply treasured. Those who knew him and realized what he had to bring to British education could not but applaud when, towards the end of 1945, the University of London appointed him to the chair of education at the Institute of Education, where, for some years previously, he had given a lecture course. Students knew his value. "It was always an inspiration to us when he lectured" is a typical comment by one of them.

Irreparable as the loss is, we can yet take some comfort in the belief that his work among us had proceeded far enough to ensure that his influence will abide, and that what he taught us concerning our own mission and destiny will remain to guide us in those trials of the spirit through which we may still have to pass. F. C.

Prof. L. W. Lyde

THE death on January 24 at his home at Cirencester of Prof. Lionel William Lyde has removed from the active list another of the small band of pioneers who laid the foundations in Britain of the modern concept of geography, and its re-recognition as a subject of university status. Chisholm, Herbertson, Mackinder, H. R. Mill, Marion Newbigin and Lyde each contributed in a different way to this revival; each brought to bear upon the problems of the new sphere of interest a mind trained in other disciplines.

The son of Canon Lyde of Queens' College, Cambridge, Lyde was born on March 28, 1863, and educated at Sedbergh and Queen's College, Oxford, where he held a classical exhibition. Literary and classical studies were the background of his work, and it was his interest in classical history which led him to the study of man in relation to his environment. His first book, "An Introduction to Ancient History" (1890), published when he was English master at Merchiston School, Edinburgh, was followed by two school text-books, "Man on the Earth" (1895) and "Man and his Markets" (1896), which undoubtedly exercised an enormous influence on the school teaching of geography. Lyde was still a comparatively young man when his publishers gave a small dinner to mark the sale of the two millionth copy of his books.

After a period in Glasgow and as headmaster of Bolton Grammar School (1899–1903), he went to University College, London, as professor of geography—in the days when colleges could appoint professors at purely nominal salaries. For many years his students could only qualify for diplomas but, through the efforts of Lyde, H. N. Dickson, A. R. Hinks and others, London instituted an honours degree, and it was Lyde who trained the seven students who were the entrants to the first examination in 1921. He was an inspiring teacher and exercised a great influence over his students. He had marked likes and dislikes—of people, their work and ideas—and he had something of the historian's worship of contemporary sources, which led him to place undue reliance on local scraps of information culled from the most varied sources. "The Continent of Europe" (1913) and "The Continent of Asia" (1933) thus combine wide reading and deep scholarship with both sound and ill-founded deductions. His appreciation of Oriental, especially Chinese, scholarship influenced his own search for an underlying geographical philosophy, and "Peninsular Europe"—a difficult book to read—is an attempt to trace the influence of peninsularity on European history.

When he left University College in 1928, Lyde returned to his old love, the classics, and published a number of books. In all this work he had the sympathy and help of his wife and his two sons.

L. DUDLEY STAMP

NEWS and VIEWS

Prof. J. W. Heslop Harrison, F.R.S.

ON September 30, 1946, Prof. J. W. Heslop Harrison retired from the chair of botany in King's College, Newcastle upon Tyne. Since that date, the University of Durham has conferred upon him the title of professor emeritus, so giving due honour to one of her most illustrious north country sons. In 1917 he went to Newcastle, holding a research appointment as a senior investigator under the Department of Scientific and Industrial Research. Later, he became a lecturer in zoology, and in 1926 was elected to a college readership in genetics. In 1927 he was appointed to the chair of botany, when the late Prof. J. W. Bews returned to South Africa. His earliest researches were concerned with biogeography. In particular, they dealt with the flora of Upper Teesdale and Lepidoptera of a bifocal distribution. His genetical and cytogenetical researches commenced with studies in interspecific hybridity and heredity in the Lepidoptera, more especially in the sub-family Bistoninæ and the genus *Oporinia.* Observing the prevalence of melanism in this genus, he studied its incidence, causes and induction in many Geometrid genera. Cytogenetical examinations in the interspecific crosses gave rise to investigations on the relations between chromosomes and phylogeny in the Lepidoptera and thence to the detection of polyploid series in the group—a totally unexpected phenomenon. In considering the effects of natural selection in wild *Oporinia* populations, Prof. Harrison saw possibilities of Lamarckian explanations. Accordingly he planned and carried out experiments (*a*) on the development of inherited, new food habits in the sawflies of the genus *Pontania*, and (*b*) on the production and inheritance of light effects in the pupæ of the butterfly *Pieris napi*. Prof. Harrison's genetical work on plants began with field observations on wild roses and willows, which led to researches in the cytogenetics of *Rosa* and its hybrids as well as of *Salix*, and the discovery that most British roses are of hybrid origin. In 1934 he commenced his work on the flora and fauna of the Hebrides. From these studies in systematics proceeded intensive studies in the biogeography of the area and in its Pleistocene and Holocene history and geography.

We have been informed that Prof. Harrison hopes to devote much time in future years to research. At present he remains working at King's College, holding for two years a College Research Fellowship, giving lecture courses on genetics and evolution, and supervising postgraduate researches in genetics. We hope that this last phase of his University career will prove as fruitful as all the varied earlier ones have been, and that many happy years are in store for him when he finally withdraws from the walls of his proud and grateful Alma Mater.

Psychology at Aberdeen : Prof. Rex Knight

The most recent addition to the number of university chairs in psychology is at Aberdeen, where Mr. Rex Knight has been appointed to the Anderson professorship. Prof. Knight was born at Wilcannia, New South Wales, in 1903, and graduated from the University of Sydney in 1923 and the University of Cambridge in 1925. He was a member of the staff of the National Institute of Industrial Psychology during 1925–28, first as an investigator, then as assistant to the director, the late Dr. C. S. Myers, and co-editor of the Institute's journal. After a year as lecturer at the University of St. Andrews, he was appointed Anderson lecturer (later reader) in psychology at the University of Aberdeen in 1929. During the War, for three years he gave a weekly broadcast commentary for the Ministry of Information, together with numerous lectures for the Central Advisory Council for Education in the Forces in remote parts of Scotland. During 1943–45 he was attached to the War Office staff of the Directorate for Selection of Personnel. His book on "Intelligence and Intelligence Tests" is widely used, and he is well known for his advocacy, in 1932, of the strictly scientific approach to animal psychology (cf. his article in *Nature* of Nov. 9, 1932, on "The Explanation of Animal Behaviour"). But Prof. Knight's main interests are in dynamic and social psychology, the applications of psychology to everyday human problems, its relation to literature and the other arts, and the role of psychology as an ingredient in a general education.

University of Glasgow

The Department of Scientific and Industrial Research has offered to supply and erect for the Department of Natural Philosophy of the University of Glasgow a 300 MeV. synchrotron, and to make a capital grant of £3,500 towards the provision of a high-voltage generator. Dr. J. M. Hyslop has resigned his lecturership in mathematics in the University on his appointment to the chair of mathematics in the University of Witwatersrand. Dr. T. S. Stevens has resigned from the Department of Chemistry to become lecturer in organic chemistry in the University of Sheffield; Drs. Stanley Alstead and R. A. Shanks have resigned from the Department of Materia Medica to become (respectively) medical consultant for the North of Scotland at Inverness and medical registrar at Yorkhill Hospital for Children, Glasgow. Messrs. C. E. Bond, R. Lambert Hurt and A. J. Webster have been appointed assistants in the Department of Anatomy, and Mr. John Higginson an assistant in bacteriology.

Mechanical Recording of Information

The system used at the Royal Cancer Hospital to record information numerically about cancer patients so that it can be transferred to a punched card and sorted mechanically is described by D. W. Smithers, K. M. H. Branson and H. O. Hartley in a pamphlet which includes also the instruction book and code book in use (from the Royal Cancer Hospital). This information should be of general interest to the medical research worker and to others who are considering the use of punched cards for bibliographic purposes or statistical analysis. The essential features of the system are the compilation of a special record card from notes on the patient, the information on the card being such that it can be expressed in numerical form and is suitable for rapid analysis by mechanical means. Filling in this card is the only extra clerical work required of the medical man, usually a registrar, beyond his usual duties of keeping accurate notes. The time required for coding and preparing the card for punching is greater, but this work can be carried out by a specially trained clerk. The special record cards remain the property of the hospital and are filed there. Most of the information on these cards can be transferred to a Hollerith punched card by a clerk trained for the purpose and employed by the hospital, or if no such clerk is available they may be sent for punching to the British Tabulating Machine Co., Ltd. As analysis of both standard data and special hospital data is made mechanically, information obtained from the cards can be supplied either to a central organisation, an individual hospital or to any clinician concerned.

The Royal Cancer Hospital and the group of hospitals with which it co-operates are giving the system a preliminary trial for all cancer patients coming under their care from January 1, 1945.

Abstracts of World Medical Literature

Two new monthly medical abstracting journals, *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynæcology*, have been published by the British Medical Association. The first (January) issues have now appeared, and even a glance through the pages shows that Dr. Hugh Clegg, editor of the *British Medical Journal*, under whose general direction they are being issued, and Dr. G. M. Findlay, who edits them with the assistance of Dr. S. S. B. Gilder and a panel of advisers, are to be congratulated on both the planning and the execution of the considerable task which they have undertaken. The foreword to both these issues traces the history of recent medical abstracting work, from the Medical Research Council's publication during the First World War, of information derived from medical literature then appearing, to the similar service begun during the Second World War and continued in the form of the *Bulletin of War Medicine*. The success of the latter encouraged the British Medical Association to continue an abstracting service when this bulletin ceased publication in 1946, and the two new journals are the result. They give, over a remarkably wide range, abstracts of articles selected from more than a thousand periodicals. Comments by the abstractors are printed inside square brackets, so that there will be no confusion between the views of the abstractor and those of the authors of the article abstracted.

The type chosen for the new journals is attractive and clear, and they are so bound that they are pleasant and convenient to use. They form a valuable supplement to the excellent epitomes of British medical literature published in the *British Medical Bulletin*, which was born in 1940 in the editorial department of the British Medical Association as a medical information service to provide, in collaboration with the Ministry of Information, foreign medical journals with surveys of current British medical literature. Later, this service was taken over by the British Council and became, under the able editorship of Dr. Howard-Jones, the *British Medical Bulletin*, which is now an essential feature of medical literature. Medical men all over the world now have, therefore, an information service which should keep them well informed of every important development.

British Standard Specification for Cable Insulation

A 1946 edition of the well-known British Standard No. 7, the first edition of which appeared in 1904, and which deals with rubber-insulated cables and flexible cords for electric power and lighting, has recently been issued. The main specification, together with a supplement on the use of polyvinyl chloride compounds as an alternative to vulcanized rubber, is published as a single volume (B.S.7; 1946. British Standards Institution, Publications Department, 28 Victoria Street, London, S.W.1. 3*s.* 6*d.*, post paid) and an amendment, entitled "Transitory Relaxations", is issued separately in the form of a leaflet (Ref. *PD* 540). War-time conditions hastened the introduction of polyvinyl chloride insulated cables, and this necessitated several modifications to the original specification. The 1946 edition, while retaining in substance all the usual features, makes allowance for the change-over to peace-time conditions. Some of the modifications referred to above are retained as permanent revisions to the specification, others are retained only temporarily, to be dropped eventually, while others have been entirely cancelled. The specification is divided into three sections: the first, of a general nature, defining terms, sizes, etc., used later in the specification; the second, dealing with the construction of the different types of cables and cords; and the third, with tests for thickness of insulation and sheath, voltage, insulation resistance, spark testing, tinning and armouring. The numerous tables with which the specification is provided make the publication an extremely useful one for all users and manufacturers of electrical cables and cords.

Durban Museum and Art Gallery

Although the annual report of the Durban Museum and Art Gallery for the year ended July 31, 1945, shows their satisfactory maintenance as cultural and educational centres, it points out the need for extensions if these institutions are to function in a manner adequate to the future needs of a city growing in both size and importance. A new building has been embodied in a post-war development scheme, and it is now recommended that this be erected as soon as circumstances permit. Schools continued to make good use of the Museum services during the year. Eighty-nine gallery talks—many of which were augmented by lantern-slide or film shows—were delivered to visiting classes, and the showing of instructional films relating to subjects lying within the scope of the Museum was a regular weekly feature. An interesting departure from the usual type of film shown in museums was one demonstrating the activities of the Durban municipal departments.

History and Comparative Study of Religion

An effort is being made to establish in Cambridge a photographic record for use in illustrating the history and comparative study of religions. Any persons, especially those returning from the Services or from the mission field, who may have photographic prints of religious buildings or ceremonies (whether Christian or non-Christian), are invited to send spare copies for this collection. Any contributions will be filed and preserved, with the names of the donors duly recorded. Communications should be sent to the voluntary curator of the record, the Rev. Dr. Bouquet, Gilling House, Madingley Road, Cambridge. It is also desired to register the whereabouts of cinematograph films dealing with the same subjects, especially if in private hands.

Summer School in Social Biology (Switzerland)

The British Social Hygiene Council proposes holding a summer school on "Social Biology: its International Aspects", in Switzerland during the last fortnight in August. It is proposed to devote one week to study and the second week to visits, expeditions and recreation. The School is intended for teachers and social workers, and others interested in social biology from Britain, but it is hoped that there will also be students from other countries. Lectures will be in English. The estimated cost, including travel, board and tuition, will be between £25 and £30. Further information can be obtained from the Secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Announcements

Mr. S. S. Carlisle, a graduate of Queen's University, Belfast, has been appointed head of the Instrument Section of the British Iron and Steel Research Association, in succession to Mr. W. C. Fahie, who is taking up an appointment in the Ministry of Defence. Mr. Carlisle joined the Association in October 1946, following four years' service in the Experimental Department, H.M.S. *Excellent*, Portsmouth, on the staff of the Director of Scientific Research, Admiralty, where he was largely responsible for the design and development of certain special recording instruments and electro-mechanical control systems associated with modern gunnery and radar techniques.

One of the activities of the Viking Fund (14 East 71st Street, New York) is the publication, in conjunction with its summer seminar in physical anthropology, of a "Yearbook of Physical Anthropology", which consists, in the main, of reproduction in full of a score of important papers appearing during the year. The yearbook is distributed free of charge to members of the American Association of Physical Anthropologists and to other interested persons. The second issue (for 1946) is now in preparation, and the editor, Dr. Gabriel Lasker, would welcome reprints and references to material which might be considered for inclusion.

LETTERS TO THE EDITORS

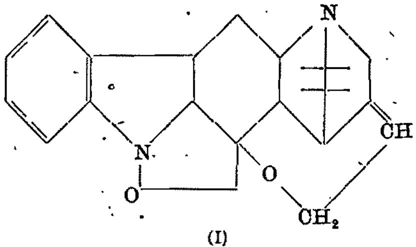
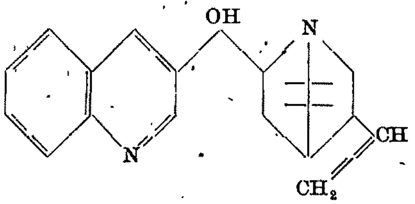
Constitution of Strychnine and its Relation to Cinchonine

The progress of experimental studies of strychnine derivatives, especially of neostrychnine, in this Laboratory has shown that no formulation hitherto suggested is adequate. Furthermore, it has not been found possible to modify the structure in a satisfactory manner on the basis of generally accepted deductions in regard to the ring containing the amide group. The validity of the simple and direct explanations of Leuchs' degradation of the strychninolones and brucinolones has therefore become questionable, and feasible alternatives of a more complicated character have been devised. These allow the amide ring to be five-membered, and on this basis an entirely novel and very satisfactory strychnine constitution (I) can be developed. This serves to illustrate the whole chemistry of the alkaloids, including the most recent findings, and must therefore be regarded as the best working hypothesis at present available. It is free from all stereochemical difficulty, and double bonds can be accommodated where necessary.



(I)



Cinchonine

It can be set up on the models in strainless stereoisomeric forms, of which the two most characteristic are those obtained by *cis* and *trans* disposition of the nitrogen atoms in relation to the central *cyclo*hexane ring. The carbon skeleton can be dissected in exactly the same way as was indicated[1] in the case of another formula (with six-membered amide ring), but the relation with cinchonine is now even closer and is at once apparent on comparison of the structures. Speaking only of the carbon–nitrogen skeleton, (I) is cinchonine in which an indole nucleus replaces quinoline, and there are three additional carbon atoms in the amide ring. This is a very striking result, and nothing similar can be achieved by retaining a six-membered amide ring.

The cinchonine formula is depicted in an unusual arrangement to facilitate the comparison with (I).

A fuller discussion and description of relevant experiments will be submitted for publication elsewhere.

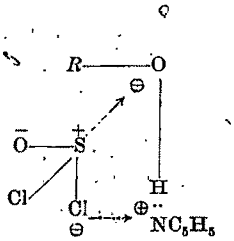
Influence of Tertiary Bases on the Interaction of Thionyl Chloride and Hydroxy Compounds

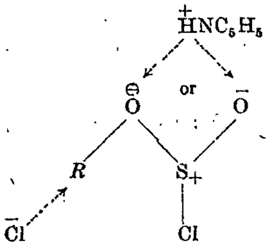
In contrast to the observations of Human and Mills[1] on the use of pyridine in the interaction of thionyl chloride and the carboxylic group, we found that instead of *one* molecular proportion of tertiary base in the Darzens' procedure[2] for hydroxy compounds, much less than 0·1 mol. of base or its hydrochloride was sufficient. Thionyl chloride (1·0 mol.) was added to a cooled mixture of the hydroxy compound (*iso*-amyl, *n*-butyl, β-phenylethyl alcohols, or ethyl lactate) (1·0 mol.), and a few drops of base (pyridine, quinoline, or dimethylaniline) or a small amount of the corresponding hydrochloride. An excellent yield of the chloride (*R*Cl) was distilled directly from the reaction mixture, after it had been heated for four hours at 65–80° (depending on the base). Yields approaching 95 per cent were obtained.

To account for the ease with which thionyl chloride forms pyridine hydrochloride and the sulphite (R_2SO_3), it was suggested by one of us[3] that the lone pair of electrons on the nitrogen atom forms a hydrogen bond with the hydroxylic hydrogen, and this facilitates properly orientated 'broadside' collisions (I). The function of the small amount of pyridine hydrochloride in facilitating the decomposition of the intermediate chlorosulphinate (*R*OSOCl) formed in the interaction of thionyl chloride and hydroxy compound may also be due to hydrogen bonding (II), the *R*—O bond being thereby sufficiently weakened to increase the probability of fruitful attack along the 'end-on' direction by such groups as Cl^- or OSOCl. The ion $C_5H_5NH^+$ is repeatedly regenerated. Certain structural features, such as a phenyl group attached to the reactive centre, may lead to deviations which can only be discussed in detail.



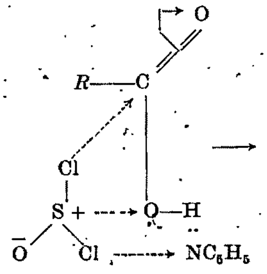
→ R_2SO_3
+ $2C_5H_5NHCl$

I



→ RCl + SO_2
+ C_5H_5NHCl

II



⟶ ROCOCl
SO_2
C_5H_5NHCl

III

Hydrogen bonding may account for the better results obtained by Human and Mills when they used pyridine in *one* molecular proportion in their experiments with carboxylic acids (III).

Absolute Values of the Rates of Unimolecular Reactions

EXPERIMENTAL unimolecular reaction-rates in gases are adequately represented by the equation:

$$K_{\text{uni}} \equiv -\frac{1}{N}\frac{dN}{dt} = a \exp(-E/kT)\ \text{sec.}^{-1}, \qquad (1)$$

where N is the concentration, T the absolute temperature, and k is Boltzmann's constant. The fact that a is in most cases found to be of the order of magnitude of intramolecular vibration frequencies (10^{14} sec.$^{-1}$) has been much discussed. By an approach akin to that of Polányi and Wigner[1], I obtained a theoretical reaction-rate in which a, although not precisely determined, was of this order of magnitude[2,3]. This result can now be made precise.

The gas molecule is treated (as before) as a classical system with n internal degrees of freedom, and n normal modes of harmonic vibration; the vibration frequencies $\nu_1, \ldots \nu_n$ of these modes are assumed to be linearly independent numbers. The time-variation of a geometrical co-ordinate q, such as the extension of an inter-atomic bond, is a sum of normal-mode terms:

$$q = \sum_{s=1}^{n} \alpha_s \sqrt{\varepsilon_s} \cos 2\pi (\nu_s t + \varphi_s), \qquad (2)$$

where ε_s is the energy and φ_s the phase-angle in the s th normal mode; on this classical picture, the ε_s and φ_s change only at molecular collisions. The 'amplitude factors' α_s are constants characteristic of the particular co-ordinate q considered.

The molecule is assumed to dissociate when one particular co-ordinate q attains a critical high value q_0. This value is attainable only after collision has raised the internal energy to satisfy

$$\Sigma \alpha_s \sqrt{\varepsilon_s} \geqq q_0, \qquad (3)$$

but the molecule dissociates only if the terms in (2) have time to come sufficiently into phase for q to reach q_0 before further collision removes the high energy. If then $L(\varepsilon_1, \ldots \varepsilon_n; q_0)$ is the frequency with which the sum (2) would attain q_0 if undisturbed, L may be taken to represent the proportion of molecules with energies ($\varepsilon_1, \ldots \varepsilon_n$) which dissociate per second.

At the high pressures at which de-energizing collisions are much more frequent than dissociations, the number of molecules with energies in the ranges ($\varepsilon_1, \varepsilon_1 + d\varepsilon_1$) . . . ($\varepsilon_n, \varepsilon_n + d\varepsilon_n$) is very nearly the equilibrium number, namely,

$$N(kT)^{-n} \exp(-\Sigma \varepsilon_s/kT) d\varepsilon_1 \ldots d\varepsilon_n.$$

A fraction L of these dissociate per second; thus the total dissociation-rate is the first-order rate:

$$K_{\text{uni}} \equiv -\frac{1}{N}\frac{dN}{dt} = \int_0^\infty \cdot \cdot \int_0^\infty L(\varepsilon_1, \ldots \varepsilon_n; q_0)$$
$$(kT)^{-n} \exp(-\Sigma \varepsilon_s/kT) d\varepsilon_1 \ldots d\varepsilon_n. \qquad (4)$$

(We can integrate from $\varepsilon_s = 0$, since $L = 0$ where (3) is not satisfied.)

Now

$$L = \tfrac{1}{2} \lim_{\tau \to \infty} \{M(\tau)/\tau\},$$

where $M(\tau)$ is the number of zeros, for $0 \leqq t < \tau$, of $q - q_0$ with q defined by (2). I used before[2] an approximate formula for this limit, but use now a formula due to Kac[4], which gives in our notation:

$$L(\varepsilon_1, \ldots \varepsilon_n; q_0) = \frac{1}{4\pi^2} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{\cos(q_0 \xi)}{\eta^2} \Big\{ \prod_1^n J_0(\xi \alpha_s \sqrt{\varepsilon_s}) -$$
$$\prod_1^n J_0 [\alpha_s \sqrt{\varepsilon_s (\xi^2 + 4\pi^2 \nu_s^2 \eta^2)}] \Big\} d\xi d\eta. \qquad (5$$

Inserting this in (4) and integrating first for the ε_s by means of Weber's formula[5], we find that

$$K_{\text{uni}} \doteq \nu \exp(-q_0^2/\alpha^2 kT),$$

where

$$\alpha^2 = \Sigma \alpha_s^2, \quad \nu^2 = \alpha^{-2} \Sigma \alpha_s^2 \nu_s^2. \qquad (6)$$

It is easily found that the minimum total internal energy for dissociation, that is, the minimum $\Sigma \varepsilon_s$ satisfying (3), is

$$E_0 = q_0^2/\alpha^2.$$

Thus, finally,

$$K_{\text{uni}} = \nu \exp(-E_0/kT). \qquad (7)$$

The factor ν in this result is, by (6), the root mean square of the vibration frequencies weighted by the amplitude factors α_s. It is thus independent of temperature, so that[3] the energy E_0 in (7) may be identified with the empirical E of (1) as the 'activation energy'.

A full discussion of this theory, with an extension to low-pressure dissociation-rates, will be given elsewhere.

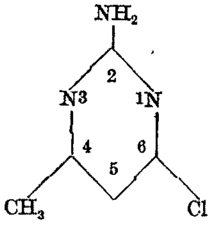
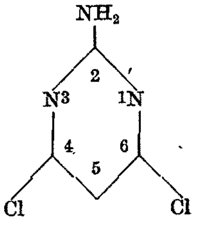
Crystal Structures of 2-Amino-4-Methyl-6-Chloropyrimidine and 2-Amino-4,6-Dichloropyrimidine

A SERIES of investigations on the structures of pyrimidines and purines is being carried out in close association with the work of Prof. A. R. Todd and his collaborators on the chemistry of these and related compounds.

No previous structural work on pyrimidines has been reported in the literature, so an extensive search was made for compounds which seemed likely to permit of a determination of structure without previous assumptions as to the nature of the pyrimidine molecule. Two isomorphous pyrimidines were selected: 2-amino-4-methyl-6-chloropyrimidine (I) and 2-amino-4,6-dichloropyrimidine (II).



(I)



(II)

Both compounds crystallize from alcohol as thin laths the lengths of which correspond to the *b*-axis. The monoclinic unit cell has dimensions, $a = 16 \cdot 4$, $b = 3 \cdot 8_5$, $c = 10 \cdot 3$ A., $\beta = 108°$, and the space-group is $P2_1/a$ (C^5_{2h}) with four molecules in the cell. The intensities of nearly 200 *hol* reflexions were determined from Weissenberg photographs of both compounds. These intensities were used in the computation of Patterson projections along the *b*-axis, and for the dichloro compound it was possible to determine x and z co-ordinates for both of the chlorine atoms. Phases could then be assigned to a number of the terms used in a Fourier synthesis which gave a first approximation to the structure. The third approximation is illustrated in Fig. 1.

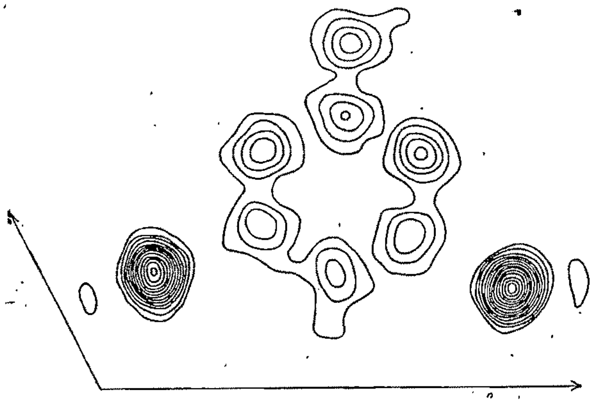


Fig. 1. 2-AMINO-4,6-DICHLOROPYRIMIDINE. ELECTRON DENSITY PROJECTED ON (010). CONTOURS DRAWN AT INTERVALS OF ·2·5 ELECTRONS PER $A.^2$

A similar procedure was adopted for the second compound, and the second Fourier projection is shown in Fig. 2. The approximate equality in height of the peaks in the 4- and 6-substituent positions is of considerable interest, as, of course, one of these should be a chlorine atom and the other a methyl group. The heights of the peaks correspond to a group the scattering power of which is the mean of that of chlorine and carbon atoms. This probably indicates that the chlorine atoms and methyl groups are distributed randomly through the structure in either the 4- or 6-positions, and this idea is supported by the Patterson projections. A similar phenomenon was reported for *p*-bromochlorobenzene by Hendricks[1], although in this case the space group ($P2_1/a$ with two molecules in the unit cell) requires a centro-symmetrical molecule.

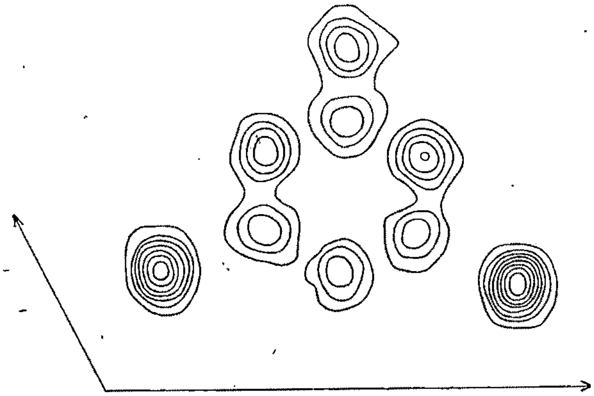

Fig. 2. 2-AMINO-4-METHYL-6 CHLOROPYRIMIDINE. ELECTRON DENSITY PROJECTED ON (010). CONTOURS DRAWN AT INTERVALS OF 2·5 ELECTRONS PER $A.^2$

Although the molecules lie almost in the plane of projection, it is not possible at this stage to give any useful data on bond-lengths and bond-angles. Further work is now in progress, from the results of which it is hoped to derive such information. The structures of *p*-dibromo- and *p*-bromochlorobenzene are also being re-examined with the view of more precise determination.

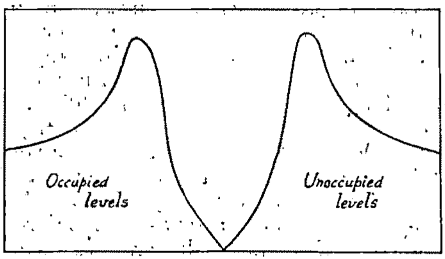
Energy Bands in Graphite

THE graphite crystal is known to consist of parallel planes of carbon atoms. The planes are about $3 \cdot 35$ A. apart, indicating[1] that the binding between them is of long-range, or Van der Waals, type. In each plane the atoms form a regular hexagonal pattern of side $1 \cdot 42$ A. The closeness of this value to that for aromatic systems such as benzene ($1 \cdot 39$ A.) or coronene[2] ($1 \cdot 41$ A.) makes it clear that in any one plane the binding consists of: (i) basic σ-type bonds resembling ordinary chemical single bonds, symmetrical around each C—C direction, and effectively localized in this region; and (ii) mobile (or conduction, or π-) electrons, which are not localized, and the symmetry of which relative to the basal plane is the same as that of a separate $2p_z$-atomic orbital, the z direction lying perpendicular to the plane. The existence of these second electrons gives the metallic character to graphite, and their behaviour may be studied by methods essentially similar to those used[2,3,4] for condensed hydrocarbons. These methods correspond, in usual metal theory, to the 'tight-binding approximation'.

Our first calculations consider the π-electrons in a single plane. These have energies which fall into a band. If we neglect overlap between adjacent $2p_z$-atomic orbitals, this band has symmetry around its mid-point. The accompanying figure shows the density $N(E)$ of energies E. The complete band accommodates two electrons per atom. As there is only one π-electron per atom available, the band is exactly half filled.

The most interesting point about this $N(E)$ curve is the fall to zero value in the middle. In fact, the curve resembles that for an insulator, but with a zero-energy gap between the allowed bands. It shows that, in its basal plane, graphite may be called a true electronic semi-conductor. At absolute zero of temperature, the lower half of the complete band is completely filled, and the upper half completely empty. As the temperature increases above zero,



electrons get into the upper half, but only in small numbers, and conduction is possible. Such conduction increases with temperature. All this is in agreement with known experimental behaviour.

Our calculations, which will be reported more fully elsewhere, have been extended to include the previously neglected overlap integral, and to take account of interaction between the separate graphite planes. The general results described above are not significantly altered.

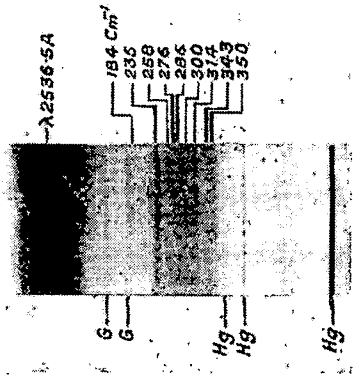
Raman Spectrum of Rock-Salt Under High Resolution

THE original investigation of Rasetti[1] as well as my later work[2] on the Raman effect in rock-salt were carried out using a Hilger medium-size quartz spectrograph for recording the faint second-order spectrum. In view of the fundamental importance of the case, it appeared desirable to re-investigate the subject, using the largest possible resolution and dispersion. Various improvements in experimental technique, including especially the efficient filtering of the exciting radiation before its entry into the spectrograph, steady running conditions of the arc and the temperature control of the spectrograph, have enabled me to work with the larger Hilger *E*1 quartz spectrograph for recording the Raman spectrum. Using a fine slit which necessitated an exposure of 160 hours, a record was obtained in which the details are not sensibly obscured by halation and which exhibits the true nature of the spectrum unambiguously.

It will be seen from the reproduction that the spectrum exhibits a set of discrete Raman lines clearly resolved from each other. The positions of the nine prominent lines with their frequency shifts in wave-numbers from the exciting line are indicated above the reproduction. The line with the frequency shift of 235 cm.$^{-1}$, to the sharpness of which Rasetti[1] directed attention in his original investigation, continues to be sharp even under high resolution. The width of this line does not exceed 3 wave-numbers if due allowance is made for the effect of instrumental and photographic factors. Its intensity is more than ten times that of the background on either side. On the longer wave-length side of this prominent line, there is an exceedingly fine line with the frequency shift of 258 cm.$^{-1}$ which is clearly discernible against the background. The intense lines with frequency shifts 300 and 314 cm.$^{-1}$ are also fairly sharp. The pairs of lines with frequency shifts 276, 286 cm.$^{-1}$ and 343, 350 cm.$^{-1}$ have a finite width, but small compared with the width of the peaks in the Born–Bradburn theoretical intensity distribution curve[3].



RAMAN SPECTRUM OF ROCK-SALT TAKEN WITH A HILGER *E*1 QUARTZ SPECTROGRAPH

It may be remarked that in many crystals, for example, diamond[4], quartz[5], calcite[6], etc., the Raman lines which appear extremely sharp at ordinary temperatures broaden to varying extents at higher temperatures. It may therefore be presumed that in the case of rock-salt as well, the observed differences in width of the various lines at room temperature are due to thermal agitation in the crystal. It appears also not unlikely that if the spectrum could be successfully recorded with the crystal held at liquid air temperature, all the lines would appear extremely sharp.

The main conclusion that emerges from the present investigation is that the vibration spectrum of the rock-salt lattice in the infra-red region of frequencies as manifested in the second-order Raman effect is a discrete one, and is different in its nature from that deduced from the lattice dynamics of Born. In view of the results of the present experimental investigation, it does not appear necessary for me to offer any further comments on the points raised by Born[7] in his recent communication in *Nature*.

THE new photograph of the Raman spectrum of rock-salt seems to me no improvement on previous work, either on that of Rasetti or of Krishnan himself. The dispersion appears to be larger, but not the resolution, so far as it is possible to judge from the reproduction. As no photometric curve is given, Krishnan's contentions about the breadth of the 'lines' are without foundation.

A complete account of the theory by Miss Bradburn and myself has meanwhile appeared[1]. It does not claim to explain all details of the spectrum, because of the simplifications and approximations which were necessary to make the problem tractable. For example, we have replaced the thirty-six branches of the rigorous formula by eighteen, omitting some and merging others. Further, we have neglected factors depending on the frequency, which may easily shift a maximum by 10 per cent of its wave-number, and we have chosen a few intensity factors in such a way that the aspect of the spectrum as a whole is correct, without considering detailed agreement. Thus the 'line' 235 cm. which Krishnan finds particularly sharp could be easily accounted for by giving our branch 9 a different amplitude.

If Krishnan would attack our method of approximation and our wholesale simplifications, I should raise no objection apart from asking him to make it better. But his conclusion that "the second-order Raman effect is a discrete one, and is different in its nature from that deduced from the lattice dynamics of Born", shows that he does not understand the theory, which is a straightforward application of quantum mechanics.

I do not intend to continue this discussion.

Diffraction of Light by High-Frequency Ultrasonic Waves

Recently diffraction patterns have been produced in this laboratory[1] by using ultrasonic waves of frequencies higher than 100 Mc./sec. At such high frequencies, the patterns show some interesting features. Progressive waves of frequency 102·6 Mc./sec. and maintained in water have been employed. When the sound wave is exactly normal to the incident light, the diffraction pattern disappears altogether. On tilting the crystal holder to one side or the other, so that the light rays meet the sound wave-front at an angle of 52′, the first-order diffraction line alone on the appropriate side is obtained. This angle agrees closely with the value derived from the equation $\lambda/\lambda^* = 2\,\mu \sin\,\theta$, where λ and λ^* are the wave-lengths employed and μ is the refractive index of water. In no position of the sound wave-front has it been possible to get the first-order line on both sides at the same time. The value of the above angle for which the first-order line attains the maximum intensity is quite critical. Even a slight variation of about 2′ has been found to reduce its intensity to half. Thus the diffraction effect at such high frequencies ($\lambda^* = 0{\cdot}00148$ cm.) appears to be very much like reflexion in the Bragg sense.

Contrary to the above results, we have found that patterns at 50 Mc./sec. show the presence of both the first-order lines for normal incidence. For oblique incidence, the first-order line on the appropriate side increases in intensity as the wave-front is tilted and attains a maximum at the corresponding reflexion angle. The first-order line on the opposite side decreases in intensity but does not vanish altogether, showing that the range of reflexion is not so sharp as in the previous case.

Bär[2], Parthasarathy[3] and others have shown that similar phenomena make their appearance, but in a less pronounced manner, at ordinary frequencies such as about 20 Mc./sec. Our investigations show that when 100 Mc./sec. is reached, the well-known features of diffraction are suppressed and the effect simulates reflexion very closely. It may be mentioned here that Nath[4] had shown that the first order would be dominant over the higher ones in the very high frequency region. Our observations are in conformity with this view.

Dimensional Changes Accompanying Capillary Condensation

Banks and Barkas[1] have recently directed attention to the mechanical interaction between capillary condensed liquid and the walls of the pores containing it, and they deduce that under certain conditions the pores may collapse when the vapour pressure over the system is lowered. However, when capillary condensation occurs, the liquid condenses on an adsorbed film—not on a bare surface—and it is to be expected that when the vapour pressure is sufficient to cause condensation of liquid, there will always be present an adsorbed film which is *mobile*. A mobile film exerts a pressure[2] numerically equal to the free-energy lowering per unit surface due to its adsorption, and in a capillary tube this pressure opposes the tension of the condensed liquid. Effects due to the pressure of a surface film have been neglected by Banks and Barkas in their calculations.

The role of the film pressure in this kind of problem may be seen by considering the dimensional changes accompanying adsorption and capillary condensation in a cylindrical cavity with very thin elastic walls. If the cavity is originally *in vacuo*, on adsorption of a vapour the film pressure φ stretches the walls of the cylinder. Changes in radius may be examined by considering the forces acting across a plane containing the axis of the cylinder. At equilibrium there is no net force acting over any imaginary plane cutting an isolated system, so that after adsorption the circumferential tension in the wall of the cylinder is equal and opposite to the film pressure φ, or $k\frac{(r_1-r_0)}{r_0} = \varphi$, where r_1, r_0 are the new and original radii and k is related to the elastic constants of the material. (When the expansion is large k may depend on the expansion; for present purposes it is treated as a constant.) Similarly, the cylinder will increase in length until the total longitudinal tension in the walls balances the longitudinal force ($2\pi r_1\varphi$) of the adsorbed film.

When capillary condensation occurs, the wall of the cavity becomes wetted by liquid and the surface pressure increases to $\varphi + \gamma \cos\theta$, where γ is the surface tension of the liquid and θ is the contact angle.

(*a*) *Changes in Radius.* Supposing the radius to remain constant at r_1, the forces acting over the plane containing the axis of the cylinder would be (i) the tension in the walls $k\frac{(r_1-r_0)}{r_0}$, (ii) the film pressure $(\varphi + \gamma\cos\theta)$, and (iii) the tension in the condensed liquid. This last quantity is $\frac{2\,\gamma\cos\theta}{r_1} \times 2\,r_1 \times 1 = 4\,\gamma\cos\theta$ per unit length, and the total expansive force per unit length acting across the plane would be

$$-\,2k\,\frac{(r_1-r_0)}{r_0} + 2\,(\varphi + \gamma\cos\theta) - 4\,\gamma\cos\theta,$$

which is not zero. Therefore, at constant vapour pressure, the cylinder would *shrink* to a new radius r determined by

$$-2k\frac{(r-r_0)}{r_0}+2(\varphi+\gamma\cos\theta)-2r\cdot\frac{2\gamma\cos\theta}{r_1}=0,$$

or, since $\varphi = k\frac{(r_1-r_0)}{r_0}$, then $\frac{\gamma\cos\theta}{\varphi}=\frac{r_1(r_1-r)}{(r_1-r_0)(2r-r_1)}$.

(*b*) *Changes in Length.* On condensation at the radius r_1, the longitudinal expansive force due to the film pressure would increase by $2\pi r_1\gamma\cos\theta$, but the tensile force of the liquid would be $\frac{2\gamma\cos\theta}{r_1}\times\pi r_1^2$, that is, it would be equal and opposite the increased expansive force of the adsorbed film. Therefore, if the radius remained constant on capillary condensation, there would be no tendency for the length of the cavity to alter. It follows that there would be no dimensional change accompanying condensation in a *spherical* cavity.

However, due to the radial shrinkage from r_1 to r, the longitudinal expansive force is reduced from

$$2\pi r_1(\varphi+\gamma\cos\theta) \text{ to } 2\pi r(\varphi+\gamma\cos\theta);$$

while the longitudinal tensile force of the liquid is reduced by

$$\pi(r_1^2-r^2)\frac{2\gamma\cos\theta}{r_1}.$$

The net decrease in the expansive force is then

$$2\pi(\varphi+\gamma\cos\theta)(r_1-r)-\frac{2\pi\gamma\cos\theta}{r_1}\cdot(r_1^2-r^2),$$

which reduces to

$$\frac{2\pi(r_1-r)}{r_1}\{r_1\varphi-r\gamma\cos\theta\}.$$

Consequently, on capillary condensation, the length of the cavity will decrease, remain constant, or increase according as $r_1\varphi$ is greater than, equal to, or less than $r\gamma\cos\theta$.

These examples illustrate the primary role of the film pressure φ as an influence on the dimensional changes accompanying adsorption. Moreover, the difference between the longitudinal and transverse effects emphasizes the importance attaching to the geometry of the deformable system. The difference between the *form* of the above equations for the radial changes and the equations of Banks and Barkas arises merely from the supposition made above that the wall of the capillary is very thin. For a wall of finite thickness, more complicated equations analogous to those of Banks and Barkas but containing an additional term due to the film pressure would be obtained. It will be noted that on slightly lowering the pressure after capillary condensation has occurred, the reduced radius will cause the liquid to remain in the capillary, that is, the radial shrinkage leads to a hysteresis in the adsorption isotherm.

Binocular Colour Combinations

INTEREST centres round the possibility that a good yellow might be made from a binocular combination of red and green, one colour presented to each eye. According to Walls, "There is no color-sensation which can be produced by mixing two lights in one eye, that cannot be duplicated by supplying two lights, independently, one to each eye"[1]. He also puts forward an interesting theory that all colour syntheses, whether monocular or binocular, take place in a single locus, believed to be the lateral geniculate nucleus (whereas fusion of binocular stereoscopic patterns may take place in the laminæ of the striate area of the visual cortex)[2].

Two colours, one supplied to each eye, may be combined by means of a simple stereoscope fitted with a colour-filter holder in place of the usual stereoscopic double picture. One colour will stimulate each eye independently.

In experiments of this kind, carried out on eleven subjects with normal colour vision, the eight Ilford monochromatic filters were used, together with Ilford Micro No. 6—a suitable purple. The nine colours were combined binocularly in pairs, starting with red on the left and taking each other colour in turn on the right; then placing orange on the left, and taking each colour except red on the right, and so on, until finally purple was combined with violet. In order to compensate for the effect of the dominant eye, whichever it was, the experiment was then repeated with the sides reversed.

The degree of combination was estimated on a ten-point scale, 0 being complete absence of combination and 1·0 being perfect fusion. Five intermediate points were used: 0·1, 0·3, 0·5, 0·7 and 0·9, in order to simplify the task and also because no colour pair completely failed to fuse or gave perfect combination. The estimates were entered in order in a 9 × 9 table, like a correlation table, and the diagonal cells were then filled with 1·0's, because they represent fusion of each colour with itself, which is always perfect.

Such a table may be factorized by the simple summation method of Burt[3], and the following factor loadings were obtained from an experiment with an experienced observer with normal colour vision.

Colours combined	General factor	First bipolar	Second bipolar
Purple	0·648	−0·247	+0·723
Red	0·735	−0·589	+0·197
Orange	0·765	−0·580	−0·076
Yellow	0·867	−0·402	−0·349
Yellow-green	0·839	−0·089	−0·676
Green	0·765	+0·145	−0·641
Blue-green	0·854	+0·638	−0·158
Blue	0·706	+0·551	+0·399
Violet	0·618	+0·573	+0·599

The general factor shows that all colours have a strong combining tendency when presented independently one to each eye in pairs. The bipolar factors show that there are decided limitations in the ways these combinations can be made. Both bipolars show that complementaries are very difficult to combine, and the second bipolar shows clearly that bright colours are difficult to combine with dark.

Red and green can be combined to a certain extent, under the conditions described, but only with considerable difficulty, and little or no support for the Young–Helmholtz theory will be found in this experiment. It clearly supports a four-colour theory of the Hering or Houstoun type, in which opposite colours would be expected to combine by a 'neutralizing' process in one eye, but not when presented separately to the two eyes, whereas neighbouring colours would be expected to combine readily in either way, which they do.

The fact that complementary colours are extremely difficult to combine when presented separately one to each eye, but very easy to combine in one eye alone, also throws doubt on the theory that all colour combinations take place in a single locus of the brain, and not in the retina. It is more likely that complementaries combine in the eye, though neighbouring colours may combine in the brain.

Social Science in the Gap between the Royal Society and the British Academy

To which of the two above-named august institutions should research workers in social science look up for recognition, guidance, grants-in-aid, expert criticism, and publication? The recent Clapham Report[1], on the Provision for Social and Economic Research, was drawn up by a committee of nine whose qualifications included three F.B.A., three Litt.D., two Ll.D., one D.Sc., but no F.R.S. This literary preponderance suggests that the appropriate body is the British Academy. But a surer guide is a comparison of publications. Those of the British Academy, though full of literary grace and social interest, scarcely contain any quantitative analysis. I doubt if a correlation coefficient could be found anywhere among them. An article in celebration of Leibniz[2] does not contain any mathematical symbols. On the other hand, the publications of the Royal Society, though full of quantitative analysis, scarcely contain any direct mention of human social relations. To which body should a quantitative analysis of a social problem, therefore, be offered for publication? Apparently to neither. There is thus an awkward gap at the highest level of authority. No such gap was intended when the British Academy was formed[3] in 1902. One of its presidents, Sir Frederic Kenyon, in his presidential address on July 4, 1918, said of academies of learning: "Their normal formation is in two classes, one comprising what we now commonly call humanistic studies, i.e., history, philosophy and philology (in the widest sense of the latter term), the other mathematics and natural science. . . . In this country the Royal Society corresponds to one of these classes. The British Academy was founded to play the other part." Since 1902 social science, like other sciences before it, has become more statistical, more quantitative, more mathematical. To give only one example: there are now many published researches on the intelligence of school-children, and on its correlations with their parentage and other social conditions. The results are important for planning, and their discussion involves matrix algebra[4]. So a gap, unsuspected in 1902, has now opened wide. Fortunately the gap is bridged by a number of specialized societies and journals publishing severally statistics, psychology and economics. In the history of science some of the papers printed in specialized journals have turned out to be quite as important as those printed by the Royal Society; for example, Karl Pearson's χ^2 test appeared in the *Philosophical Magazine* for 1900. Nevertheless, a gap remains, because the specialized societies lack the breadth and the general authority of the senior bodies.

I have here emphasized only one of the aspects of a problem which has been explored in general by a Committee[5] on Scientific Research on Human Institutions appointed by the British Association. Reference should also be made to the review[6] of the Clapham Report by Prof. P. Sargant Florence.

Relationships between the Assemblages of Plants Fed Upon by Different Insects, and between the Assemblages of Insects that Feed Upon Different Plants

In the course of a recent investigation of the food-plants of the Chrysomelidæ, a family of about 27,000 species of phytophagous beetles, I have tabulated all available records in relation to the systematic groups simultaneously of the beetles and of the food-plants concerned. The results of this investigation have not yet been published, but they lead me to consider that it would be of interest to investigate the extent to which the following propositions are true for insects in general:

If insects of any given species can feed on plants of more than one species, then insects of any other species that can feed on any of these plant species can feed on all these plant species.

If plants of any given species are fed upon by insects of more than one species, then plants of any other species that can be fed upon by any of these insect species can be fed upon by all these insect species.

A priori, these propositions are suggested by analogy. It is at once apparent that they cannot be true without exception, if only because it is known that changes in food-habit are possible in Nature. Moreover, it is an empirical fact that exceptions are observed. Nevertheless, my work on the food-plants of the Chrysomelidæ indicates that these propositions contain a sufficiently large element of truth to be of service in this family as standards for comparison, as bases for prediction, and as indications of possible directions for further observation.

I should welcome the comments of other workers on the extent to which these generalizations are found to be valid and useful in other groups of insects.

Allometry of the Vertebrate Brain

Fifty years ago, Dubois[1] investigated the relationship between the brain and body-weights of certain mammals. Unaware of the work of Snell[2], he adopted an expression of the form

$$y = bx^{\alpha} \qquad (1)$$

to describe this relationship, where x is body weight, y is brain weight and α and b are parameters to be determined from the observations; α was termed the phylogenetic constant and b the cephalization constant.

Similar results were obtained by Lapicque[3], and the investigation was continued by Girard[4], by Dubois himself[5], and later by Brummelkamp[6]. A considerable number of papers has appeared, and summaries of the results have been given by Ariens Kappers[7] and de Beer[8].

The conclusions of Dubois and his successors may be briefly stated: (1) The phylogenetic constant, α, is invariable for groups of adult animals of different species within a genus or family and has the value 0·56. (2) When adult animals of different sizes but belonging to the same species are considered, the value of α is 0·26. This intra-specific coefficient is known as the ontogenetic constant. (3) The cephalization coefficient, b, is always an integral multiple of $\sqrt{2}$ (Brummelkamp).

Dubois transformed his formula into the form

$$\log y = \log b + \alpha \log x, \qquad (2)$$

and writing

$$\alpha_{ij} = \frac{\log y_i - \log y_j}{\log x_i - \log x_j} \quad \begin{matrix} (i,j = 1, 2 \ldots n) \\ (i > j) \end{matrix}$$
$$= \alpha_q$$

he then selected 'suitable' pairs of values, say k $(k < n)$, calculated the α_q for each pair $(q = 1, 2, 3 \ldots k)$, and finally put

$$\alpha = \frac{1}{k} \sum_{q=1}^{k} \alpha_q.$$

He found that the value of α was approximately 0·56.

This method was ultimately used for a number of groups of animals in order to find both the phylogenetic and ontogenetic constants. Afterwards, the value 0·56 was substituted back into the equation and treated as a kind of universal constant; given y and x, b could then be readily calculated. Various hypotheses as to the magnitude and relationships of the cephalization coefficients were then elaborated.

There is little need to point out the inadequacy of such a method of estimating parameters, and von Bonin[9] saw clearly that such a choice of 'suitable' values begged the whole question of cephalization and the development of higher mental qualities. Moreover, it is obvious that it is impossible to make any comparisons between different values of the parameters since no significance tests could be derived.

During the course of an investigation into the growth and organisation of the vertebrate brain, I have had occasion to consider this allometric formula. The values of the parameters and their standard errors may be estimated by maximum likelihood methods from either of the two forms of the equation (1) and (2). If the logarithmic form is used, the normal equations should be suitably weighted, which, so far as I am aware, has not been adequately recognized up to now. I have, in fact, considered the regression of $\log y$ on $\log x$ and used y^2 as a weighting factor. The justification for the use of this factor will be discussed elsewhere. I have applied this method to the data available to the authors cited—usually to the figures quoted in their papers. It is a little difficult always to decide upon what principle the data were chosen from Hrdlička and Weber, but I have made use of these data with the addition of some observations from Spitzka[10] for the *Macaca* species. It may be noted that frequently mean values of an unspecified number of observations have been used by previous authors as if they had the validity of the observations themselves.

My results are summarized in the accompanying table.

Group of animals	Number in group	Value of $\alpha \pm$ standard error	Value of $b \pm$ standard error
Reptiles	20	0·58±0·13	0·014± 0·05
Birds	25	0·37±0·004	0·69 ± 0·02
Primates	40	0·38±0·0002	5·3 ± 0·02
Rodents	32	0·62±0·005	0·12 ± 0·002
Between Sciuridæ	35	0·60±0·006	0·20 ± 0·005
Between Muridæ	9	0·51±0·04	0·10 ± 0·02
Within Sciuridæ:			
S. rufiventer	5	Not significantly different from zero	8·96 ± 0·28
S. carolin	17		7·60 ± 0·84
S. hudson	7		4·10 ± 0·17
Sciuropt. volans	6		1·96 ± 0·08
Between *Macaca* spp.	75	0·18±0·0001	21 ± 0·001
Within *Macaca* spp.:			
M. cynomolgus	5	Not significantly different from zero	58·5 ± 5·8
M. nemestrinus	8		112·9 ±11·2
M. pileatus	9		63·7 ± 5·1
M. rhesus	53		80·0 ±10·5

It will be seen that the value of the inter-specific (phylogenetic) constant, α, varies widely from the value 0·56. Even in such closely related animals as the Sciuridæ and Muridæ, it can be shown that the values are significantly different.

For all those species which I have considered, the intra-specific (ontogenetic) constant differs from 0·26 and, in fact, does not differ significantly from zero. This implies that if we are justified in fitting an equation of this form, the brains of adult animals of the same species have weights which only vary by random amounts.

In view of these results it would appear that Brummelkamp's hypothesis as to the relationship between cephalization coefficients is untenable.

I must emphasize that I do not consider these data to be adequate for the foundation of hypotheses concerning the quantitative organisation of the brain and the appearance of the higher mental activities in phylogeny or ontogeny. I am inclined to think that the values of parameters estimated from large groups of very different genera, for example, rodents, are of very little interest.

Dart of an Extinct Mollusc

THE dart in most Belogona is a fragile structure, and although no more perishable than other small calcareous bodies it does not seem to have been found with any frequency as a fossil.

The portion of dart illustrated here is that of the extinct sub-fossil form of *Cepæa nemoralis* L. which occurred in sand dunes at Dog's Bay, Co. Galway, prior to the erosion of the deposit. The mollusc has been referred to the var. *pura* Westerlund (= *ponderosa* Malm.), and a close relative still exists in the Dartry Mountains, Co. Sligo. The fragment, comprising the tip and about a third of the shaft, was

DART OF *C. nemoralis pura* WEST. × *c.* 6

found by sifting material scraped out of a batch of sub-fossil shells sent me by A. W. Stelfox, collected in 1909. It is interesting, in view of the suggested relationship of this form to *C. tonnensis* Sandberger, to notice that the dart is closely similar to that of the living typical *nemoralis*, although it is rather larger.

I can find no previous record of any dart recovered from sub-fossil material. It might be worth searching for more, and it seems possible that careful X-ray examination of palæontological specimens might provide some evidence of the nature of the dart in other extinct forms.

Detoxicating Effect of Verdoperoxidase on Toxins

A GREEN ferment with peroxidase activity named 'verdoperoxidase' was isolated from leucocytes in 1941, the amount present in cells being estimated as 1–2 per cent[1]. Verdoperoxidase seems to be located in the eosinophile granules, for Neumann[2] showed that eosinophile granules prepared by tryptic digestion of leucocytes were greyish-green in colour and had peroxidase activity.

The localization of verdoperoxidase and the remarkably high content of the ferment in the leucocytes have led me to undertake investigations to ascertain whether it has a special function in combating infectious diseases. Such an assumption is supported by several earlier observations. In severe infectious diseases, the oxidase granules in the polymorphnuclear leucocytes disappear. Injections of oxone (oxidases and peroxidases) from leucocytes and bone-marrow[3] prolonged by a day or so the life of animals infected with *Ty. mur.*, *B. antrax* and *B. recurrens.* According to Kojima[4], phenol is oxidized by peroxidase and hydrogen peroxide to form a substance with bactericidal action. Petherick and Singer[5] studied the detoxication of bactericidal toxins by metal catalysts. In cases of infectious diseases, Möllerström[6] found an increase in the peroxidase content of the blood-plasma. This increase he considered to be due to a release of peroxidases from leucocytes upon their disintegration.

Experiments have now been performed in order to ascertain whether bacterial toxins could be detoxicated by verdoperoxidase in the presence of peroxides. The most suitable peroxide concentration for the verdoperoxidase action is not yet known. At that concentration, 0·0015 *N*, which is used in the determination of the purpurogalline number of the verdoperoxidase, the ferment is gradually inactivated. The experiments described below were therefore arranged in such a way that the hydrogen peroxide content in a mixture of toxin and verdoperoxidase was gradually increased by dialysis up to the concentration 0·001 *N*. In these preliminary experiments dialysis continued for 24 hours; inactivated verdoperoxidase was replaced by additional amounts of fresh ferment after 6, 12 and 18 hours.

Ten ml. of diphtheria toxin were mixed with 0·35 mgm. verdoperoxidase in a 'Cellophane' bag and dialysed for 24 hours against a solution containing NaCl 0·7 per cent, Na_2HPO_4/KH_2PO_4 *m*/150 *p*H 7·4, and H_2O_2 *N*/1,000. Temp. 20° C. After 6, 12 and 18 hours 0·20 mgm. verdoperoxidase was added.

From experiments on animals it appears that toxin treated in this way was detoxicated (see Table 1). In order to make sure that this detoxication was due to the peroxidase effect of the ferment, the following control experiments were carried out:

(1) Diphtheria toxin mixed with 0·20 mgm. crystalline horse radish peroxidase and diphtheria toxin alone were dialysed as described above.

TABLE 1. TIME OF DEATH IN HOURS. THE ANIMALS WERE OBSERVED EVERY THIRD HOUR DURING THE FIRST TWO DAYS AND THEN TWICE A DAY

Toxin concentration	Diphtheria toxin + verdoperoxidase + hydrogen peroxide	Diphtheria toxin + peroxidase + hydrogen peroxide	Diphtheria toxin + hydrogen peroxide	Diphtheria toxin + verdoperoxidase	Diphtheria toxin + peroxidase	Diphtheria toxin

(2) Toxin + verdoperoxidase, toxin + horse radish peroxidase, and toxin alone were dialysed against a solution of the composition described above, but without any hydrogen peroxide. Peroxidase has a purpurogalline number 10–20 times higher than that for verdoperoxidase, and the amount of the former used, 0·20 mgm., was thus somewhat greater than the equivalent of the latter; but it was not necessary to make any further addition of the peroxidase during the experiments.

The dialysed solutions were diluted 10, 30, 10^2, 3×10^2, 10^3 and 3×10^3 times, and 2 ml. of these diluted preparations were injected subcutaneously into guinea pigs. Two animals were used for every dilution. Table 1 shows how long the animals lived after the injections.

Experiments with tetanus toxin have been carried out in the same way as those described above for diphtheria toxin. The toxin was diluted 30, 10^2, 3×10^2, 10^3, 3×10^3 and 10^4 times. 0·5 ml. of the diluted preparations were injected in the caudal veins of mice weighing 14–15 gm. Three animals were used for every dilution. The results are shown in Table 2.

These experiments show that, together with hydrogen peroxide, peroxidases detoxicate diphtheria and tetanus toxins. This is probably one of the functions of verdoperoxidase in the organism. The toxin preparations were not purified, so it is possible that the preparations contain substances which after oxidation inhibit the action of the toxin. It is, however, more probable that the toxin itself contains an oxidizable group responsible for the toxicity.

Experiments are being carried out to ascertain whether the immunizing effect persists for the toxins treated in the manner described above, whether verdoperoxidase can inhibit the toxic effects in animals injected with active toxins, and whether also other toxins may be detoxicated.

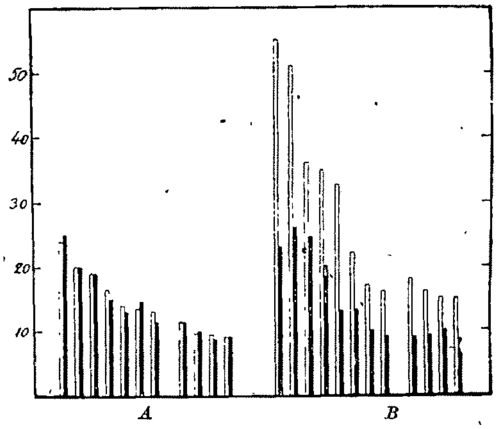
Curative Effects of a Complex Choline Compound on the Impaired Metabolism of Choline-deficient Rats

IN a previous note in *Nature*[1] we have reported experiments showing that impairment of the oxidative metabolism is a very early symptom in choline deficiency; and we concluded that choline is essential for intermediary metabolism, by being used in the formation of an unknown bio-catalyst or coenzyme. Later experiments have emphasized the specificity of choline; the curative effect cannot be produced by injections of methionine or methionine + ethanol amine.

In a series of communications[2-6] we have shown the presence of a new choline compound, the acetylcholine percursor, which is not only the immediate source of liberated acetylcholine, but most probably necessary also for purely muscular functions. We therefore tested the effects of an impure preparation of this substance on the metabolism of minced muscles from choline-deficient rats.

Ox spleen was extracted with ethyl alcohol, which was then concentrated *in vacuo*, washed with ether or petroleum ether, dissolved in water, and precipitated with acetone, as described in an earlier communication[7]. For the experiments we used albino rats, 28 days old, which were placed on the choline-deficient diet already described[1]. They were used for metabolism experiments on the fifth to seventh day on the test diet. Animals with renal hæmorrhages were not used, as uræmia itself slows[4] down the decolorization of methylene blue, and is not influenced by injections of choline. This effect was checked by using normal animals after nephrectomy.



TIME (MIN.) REQUIRED FOR DECOLORIZATION OF METHYLENE BLUE *in vacuo*

A, CONTROLS; *B*, CHOLINE-DEFICIENT RATS

White columns represent the mean of two values on muscles only; black columns adjacent represent the mean of two values from the same muscles with addition of spleen extract corresponding to about 1 gm. of fresh spleen. In each Thunberg tube: 1·250 γ methylene blue, dissolved in 2·5 ml. of m./15 Sörensen phosphate buffer *p*H 7·15, and 0·2 gm. of minced muscles of hind limbs

As seen from the graph, addition of the spleen extract to the Thunberg tubes normalizes the impaired metabolism of minced muscles from choline-deficient rats, but it has practically no effect on muscles from control animals on the same diet plus 0·6 per cent of choline chloride. Thus, the disturbances in metabolism are prevented or cured by choline in the food or in injections, but choline has no effect *in vitro*; it must pass through the organism to be transformed into a bio-catalyst; the extract is effective *in vitro* and probably contains the complete catalyst.

It is not yet possible to decide if the active principle of the extract is identical with the acetylcholine precursor. We know that the precursor decreases in muscles of choline-deficient rats[6]; we know that the metabolic factor probably is a complex choline compound and that this factor and the precursor have the following characters in common: both are soluble in alcohol and in water but insoluble in ether and petroleum ether, both are precipitated from aqueous solution with acetone and barium salts, and both are destroyed when boiled with strong acids but are more stable in slightly acid solutions.

Barium salts added to a watery solution of the acetone powder produce a precipitate; after centrifugation the clear solution is inactive. We have, however, not been able to regain the metabolic factor from the barium precipitate. If a solution of the acetone powder in 2 N hydrochloric acid or in 1 N sodium hydroxide is boiled for 15 minutes, cooled, neutralized and again precipitated with acetone, the precipitate has lost its metabolic activity. At pH 4 it can be boiled for 30 minutes without losing its activity.

Full reports are being published in *Acta Pharmacologica et Toxicologica*.

A New Unit in Photo-electric Colorimetry

The quantity $E_{1\,\text{cm.}}^{1\,\text{per cent}}$ does not always lend itself to be used in photo-electric colorimetry. As absorption is generally determined where strong bands occur, a 1 per cent solution in a layer of 1 cm. gives in most cases a reading far below the range of sensitivity of the instrument. Furthermore, it will be found that in many cases the Beer–Lambert law cannot be used for extrapolating from $E_{1\,\text{cm.}}^{1\,\text{per cent}}$ values those concentrations which cover the useful parts of the scale.

The use is, therefore, suggested in practical work of the 'half-value' of the substance, that is, the weight (in grams) of a substance which has to be contained in one ml. solvent in order to reduce the transmitted light by a half, the length of path being 1 cm., and the light transmitted by the solvent alone being unity. The proposed symbol for this quantity is $W_{1\,\text{cm.}}^{50}$.

Several advantages are claimed for this suggestion. First it should facilitate the reproduction of data obtained from a different instrument, as it refers to the most sensitive part of the scale; secondly, if, for example, in medical biochemistry, a test has been worked out so as to have its mean at a colorimeter reading of 50 per cent transmission, readings above and below this mean are, over a wide range, practically equally reliable. Often no allowance is made for the fact that the measured transmission depends on extraneous factors as well, such as colour-temperature of the filament, monochromaticity of the filter, and characteristics of the photo-cell. Thus it can be easily shown on a filter-colorimeter that the apparent transmission of a coloured fluid varies when the colour-temperature of the lamp is altered, as the filters are not strictly monochromatic. The steeper the slope of the absorption curve of a fluid, the greater this error will be. For example, solutions of potassium dichromate which exhibit strong absorption in the violet but pass red freely show this phenomenon for blue and green. The use of $W_{1\,\text{cm.}}^{50}$ can overcome part of these difficulties.

In practical work the half-value of a substance is quickly arrived at by taking two concentrations yielding transmissions above and below the half-value. From either concentration $W_{1\,\text{cm.}}^{50}$ is calculated, assuming that the solution obeys the Beer–Lambert law. Both estimates are now pooled. Then two new solutions are prepared, containing slightly more/less than the expected half-value; whence $W_{1\,\text{cm.}}^{50}$ is accurately found.

A worked example of this principle is set out below. Standardized hæmin (for which we wish to thank Prof. E. J. King) is treated with alkali[1]. Its $W_{1\,\text{cm.}}^{50}$ is found to be 0·000 039 4 gm./ml., when determined in a 'Lumetron' photo-electric colorimeter, using a monochromatic Corning glass filter with a peak at 515 mμ. The practical usefulness of such a statement may be greatly enhanced by stating $W_{1\,\text{cm.}}^{50}$ for potassium dichromate under identical conditions (in our case 0·00285 gm./ml.); for in the absence of the original material, the potassium dichromate may serve as a handy secondary standard. When both are available an additional check is afforded.

Digestibility of Cow's and Buffalo's Milk

The cow is the main animal for milk production in the world. In Africa, Asia and some parts of Europe, the buffalo is used as well as the cow to provide milk for human consumption. In Egypt, the statistics of the Ministry of Agriculture in 1937 record 956,036 buffaloes compared with 983,219 cows. The average composition of cow's and buffalo's milk in Egypt, as a result of a series of analyses of milk given by the Faculty of Agriculture herd for two consecutive years, was found to be as follows:

	Density at 15° C.	Moisture %	Dried subst.	Proteins %	Fats %	Ash %	Lactose %
Cow's milk	1·0325	85·90	14·10	3·75	4·91	0·80	4·66
Buffalo's milk	1·0316	83·01	16·99	4·39	7·30	0·83	4·47

The composition differed mainly in the percentage amount of fat; whereas in cow's milk it was 4·91, it was 7·30 in buffalo's milk. This variation in the amount of fat raised the question whether the high amount of fat in buffalo's milk decreased the digestibility of the other constituents of milk. In Egypt, physicians, under the influence of this notion, have prescribed cow's milk in artificial lactation and clinical dietetics, as it was thought to be more digestible than buffalo's milk. It was therefore thought worth while to test the digestibility of cow's and buffalo's milk.

For this purpose, three sheep, one less and two more than one year old, were selected at the Experimental Station of Animal Nutrition of the Faculty. They were kept separately, each in a metabolism box. Before determining the digestibility of milk, a separate experiment was performed first on the same sheep to measure the digestibility of hay which would be given to supplement the milk. The same sheep then received a measured amount of milk supplemented with a weighed amount of hay. The experiment was divided into two periods: seven days as preliminary period and ten days as original one. The amount of hay and of milk given was just sufficient for maintenance. Cow's milk was used first, and then the experiment was repeated using buffalo's milk. The sample of milk given daily was prepared from the daily mixture of cow's or buffalo's milk collected from the Faculty's herd. A sample of milk as given to the sheep was taken daily, and its density and the percentage of dried matter, fats, proteins and lactose determined. Fæces were collected daily and dried in an oven at 70° C., and then ground at the end of the experiment and kept for analysis.

The final figures for the digestibility of the different constituents of both types of milk from the average figures obtained from the three sheep, with the exception of lactose (means of two sheep only), were as follows:

Coefficient of digestibility of	Dry matter	Proteins	Fats	Lactose
	%	%	%	%
Cow's milk	79·21	83·18	97·07	75·27
Buffalo's milk	77·04	83·87	97·62	74·78

From these results, it can be concluded that the digestibility coefficients of the different constituents of buffalo's milk are practically equal to those of cow's milk. As regards protein digestibility, we have verified this result in a separate experiment using pepsin and hydrochloric acid, when it was found to be 95·01 for cow's milk and 95·47 per cent for buffalo's milk. It seems, therefore, that the relative high amount of fat in buffalo's milk did not affect the digestibility of proteins and fats. The figures of the digestibility coefficients of lactose obtained in our experiment were low, although it is known that the digestibility is very high; this may be attributed to the bacteria present in the stomach of the ruminants. The idea of medical men that cow's milk is preferable to buffalo's milk, in our opinion, has no physiological basis.

Rancidity in Indian Butter Fat (Ghee)

CHANGES in analytical characteristics following upon the onset of rancidity in butters and butterfats have been widely studied[1-6], with somewhat discrepant results. This is scarcely surprising in view of the number of variables involved, within the material itself and in the conditions of its spoilage. In the work here reported, the samples of ghee were prepared with some care and represent genuine products in good condition; the specimens examined were not chosen at random but belonged to three definite types—one, from Kirkee, of high Reichert value (30–40) and low iodine value (*c.* 28) typical of well-kept dairy buffaloes, another of normal Reichert value (*c.* 25) and iodine value (*c.* 38) from dairy cows, and the third of low Reichert value (14–22) and high iodine value (33–40) derived from buffaloes fed mainly on cotton-seed. The samples had all been stored in similar conditions, namely, in glass bottles with fairly loose-fitting wooden corks placed in a laboratory cupboard for periods of three to four years at a temperature range of 15–25° C. The analytical characteristics of the samples were determined before and after storage, and the average changes in each group were as below.

CHANGES IN THE ANALYTICAL CHARACTERISTICS OF GHEES ON STORAGE

	A. High Reichert value, low iodine value. (11 samples)	*B*. Normal Reichert value, normal iodine value. (12 samples)	*C*. Low Reichert value, high iodine value. (10 samples)
Acid value	+24·9	+10·0	+ 18·2
Peroxide ,,	+69·4	+64·9	+107·8
Reichert ,,	+ 4·3	+ 4·1	+ 3·9
Polenske ,,	+ 1·19	+ 0·93	+ 0·76
Iodine ,,	−10·8	− 8·3	− 16·4
Saponification value	+14·7	+11·1	+ 13·6

In the three groups, changes in individual samples were all very similar to the average changes listed in the above table; while the parallelisms between the alterations in each characteristic suggest that they all proceed from a single general cause. Large increases in acid value (usually also associated with large increases in peroxide values) were almost invariably accompanied by large increases in Reichert, Polenske and saponification value, and, most significantly, by big falls in iodine value. The inverse relation between rise in acidity and loss in iodine value indicated oxidative rancidity as the dominant factor in the normal spoilage of butter-fat in the tropics; this inverse relationship is strikingly evident in the smooth curves obtained when acid values are plotted against iodine value losses.

In a further effort to investigate the course of spoilage, the individual specimens in each of the three groups were mixed and the free fatty acids separated, the characteristics of the rancid product and its neutral and acidic constituent fatty acids being then determined. The free acids from each group had high Reichert and Polenske and saponification values and very low iodine values (14–20). Lower acids had presumably been produced by oxidation of unsaturated acids, mainly oleic, rather than by lipolysis from lower fatty acid glycerides, since the Reichert and Polenske values of the de-acidified ghees closely resembled those of the original specimens when fresh (showing that these glycerides had largely remained intact). The low iodine values contrasted with the high figures obtained for the free fatty acids from rancid butter by Davies[7], and again pointed to a mainly oxidative mechanism producing free acidity in butter-fat as opposed to a lipolytic one (somewhat selective towards oleic glycerides) in butter.

Work is in progress here on the more exact nature of the free fatty acids, an account of which will be published later. The work above reported was carried out at the Department of Biochemistry, Indian Institute of Science, Bangalore, India, and grateful acknowledgment to Mr. B. N. Banerjee and Prof. V. Subrahmanyam is made for their interest in its progress.

RESPIRATION OF DEVELOPING ANTHERS

By Dr. RALPH O. ERICKSON

Department of Botany, University of Rochester, New York

UNDER greenhouse conditions the growth in length of flower buds of *Lilium longiflorum* is exponential over the period of about five weeks preceding anthesis, during which they elongate from about 10 mm. to about 155 mm. Blackman's[1] formula can be fitted satisfactorily to the growth curves, if length is substituted for weight ($L_t = L_0e^{rt}$). Hence, the length of a bud may be taken as an index of its age, and logarithms of bud-lengths may be used in lieu of time in describing the development of the bud. For example, the average value of r, in the terms of this formula, for twenty-six buds the lengths of which were recorded each day from February 11 to April 8, 1946, at greenhouse temperatures fluctuating between average daily limits of 16° C. and 27° C., is 0·0765. At this daily 'interest' rate, a bud would grow in length from 10 mm. to 100 mm. in 30·1 days. Dividing the distance from 10 mm. to 100 mm. on a logarithmic scale of bud-lengths into thirty equal parts produces a linear scale of days.

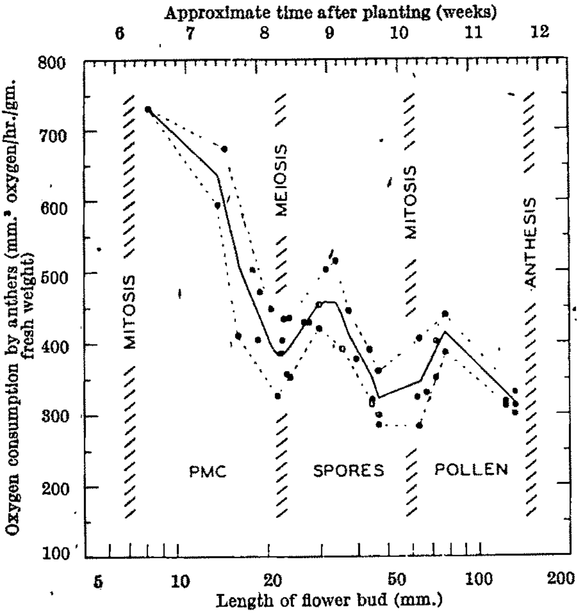
In the development of pollen within the anther, four significant events are: (1) mitotic division of the archesporial cells, which yields sporogenous cells, later microsporocytes; (2) the meiotic divisions of the microsporocytes (pollen mother cells), which yield quartets of microspores; (3) mitosis of the microspore nuclei, which yields binucleate pollen grains; and (4) anthesis, which leads to dehiscence of the anthers and release of the pollen. These four events have been located at the appropriate points on the accompanying figure, on the basis of microscopic examinations of the contents of anthers from buds of known length. The time interval, when $r = 0{\cdot}0765$, between (1) and (2) is about fifteen days; between (2) and (3), about thirteen days; and between (3) and (4), about twelve days. Detailed data supporting these statements will be presented elsewhere.

For all the microsporocytes, microspores or pollen grains within the six anthers of a bud, these nuclear events are much more closely synchronized than in the case of the cells of most other growing organs; for example, a root tip. Since the anther presents at a given time a large number of cells in the same phase of mitotic or meiotic division, it is a favourable object for investigating possible correlations between cytological and physiological processes. Preliminary evidence of one such correlation is reported below.

The respiratory rates of excised whole anthers of *Lilium longiflorum*, from flower buds of various lengths, have been determined at 25° C., in Fenn[2] microrespirometers. Each respirometer vessel contained from one to six anthers, depending on their weight. The anthers were not submerged, nor were the vessels shaken. Readings of oxygen uptake were continued, in most cases, for three hours after dissection of the buds. Determinations of the rate in oxygen, nitrogen, and mixtures of these gases showed that respiration of the anthers was not limited by oxygen tension at tensions greater than one fifth of that in the atmosphere. Rates in air were reasonably constant during the three hours over which most of the determinations extended.

The respiratory rate in air for each sample of one or more anthers, usually during the first hour after dissection, has been plotted in the figure against the length of the bud. A time-scale of days and weeks has been superimposed on that of bud-lengths. The limits within which all the data lie are indicated by broken lines, and the solid line has been drawn midway between these extremes.

The youngest anthers, from a bud 8·1 mm. long, were essentially meristematic in character and respired at the rate of 731 mm.^{3} of oxygen/hr./gm. fresh weight. As the anther differentiates and approaches maturity, there is a general decline in its respiration to less than one half of the original rate. The three oldest anthers studied, from a bud 132·4 mm. long, about two days before anthesis, respired at the average rate of 314 mm.^{3} of oxygen/hr./gm. fresh weight. Such a decline in respiratory intensity is a usual concomitant of development and maturation of plant organs. But superimposed on this decline are two fluctuations which coincide with the meiotic divisions of the microsporocytes, and with mitosis of the microspore nuclei, respectively. Each of these fluctuations consists of a fall below the prevailing respiratory level, and a subsequent recovery. The presumption is that the two fluctuations reflect temporary diminutions, or even cessations, of respiration of the microsporocytes and microspores as they divide. One would expect fluctuations in the respiration of these cells to be damped by the presence of the anther wall and tapetum. It would be desirable, therefore, to determine the respiratory rates of isolated microsporocytes, microspores and pollen.



H. Stern[3] has observed a pronounced increase in permeability of microsporocytes of *Trillium* during meiosis. There is evidence in his data and in those presented here that the division of a cell entails a profound departure from its metabolism during the interphase. Since most studies of the metabolism of growing tissues necessarily integrate the behaviour of many cells at various stages of division, a disturbance of the physiology of single cells during division would not ordinarily be apparent. Further exploration of the possibilities inherent in this study of the physiology of developing anthers may prove to be a profitable means of increasing our understanding of the mechanism of cell division in general, and of the unusual character of the meiotic divisions in particular.

NATIONAL RESEARCH COUNCIL OF CANADA

ANNUAL REPORT

THE twenty-ninth annual report of the National Research Council of Canada, 1945–46 (Pp. 65. From the offices of the Council, Ottawa), includes the report of the President, together with reports of the Directors of Divisions, the financial statement and details of scholarships awarded. Among the outstanding developments in 1945–46 mentioned in the President's report are the investigations relating to atomic energy, the release of information on radar research, the design and construction of a plywood tailless aircraft and the development to the pilot-plant stage of a process for butylene glycol from wheat. Gauge inspection work was brought to a close in September 1945, and a building research conference laid plans for co-ordinating studies and initiating practical schemes for the improvement of housing in all its branches, including construction, plumbing, heating, ventilation, lighting and the planning of housing projects with regard to their economic and social aspects. Much work undertaken for the Services as a war measure will be continued in peace-time, but with industrial and commercial applications; for example, applications of radar as aids to air and sea navigation, medical researches on the control of infectious diseases, studies on shock and blood substitutes, the development of plastic prostheses for artificial limbs, studies on heat-retaining properties of textiles used in clothing, shrink resistance of woollens, particularly socks, and wearing qualities of leathers and leather substitutes used in boots.

In the laboratories at Ottawa, the reconversion to peace-time applications of war research and the initiation of new problems are proceeding rapidly; the staff now numbers about 1,400, of whom one half are of professional grade. Through pilot-plant operations, the Structures Laboratory has gained much valuable experience in the use of synthetic resin adhesives, plywood moulding techniques, the application of glueing pressures to complicated assemblies and on the advantages and deficiencies of various glue-lime heating methods and similar problems. A recent inquiry concerning the Kingsville Harbour on Lake Erie handled by the Hydrodynamics Laboratory, in which an alternative was sought to the annual dredging necessary to maintain the navigational channel between the parallel piers protecting the harbour, involved construction of a miniature replica of the harbour and simulation of the conditions affecting the formation of the sand-bar before proposals for the extension of the longer pier could be formulated. Work is also in progress on another model dealing with the formation of sand-bars in the Fraser River.

In the Physics Laboratory, a main objective of work in radiology has been to develop new and improved instruments for the location of radioactive ores and the measurement of such ores and their products. New techniques have been developed for X-ray and radium radiography, and other investigations have dealt with the use of X-ray diffraction and electron microscopy in the examination of catalysts, pigments, rubber-compounding ingredients and other industrial materials. High-voltage research is being continued, and studies are being made of recently developed insulating materials, as well as of improved safety codes, new methods of house wiring and problems of rural electrification. Special electrical problems of the Chalk River atomic energy project are now demanding the attention of the Laboratory, while the Chemical Engineering Section of the Applied Chemistry Branch of the Division of Chemistry is giving attention to the design of the water-treatment plant for the same project as well as to the design of pilot-plant and full-scale plant for the extraction of fissile materials. The echo method of submarine detection is being investigated for its possible use in prospecting and in the detection of flaws in solid structures, while possible industrial uses of high-intensity and high-frequency sound are also being considered. Special investigations in physical oceanography initiated during the War are being continued in collaboration with other Government departments and the Canadian marine industry. A new method of heating houses by floor or ceiling radiant heat panels is being developed, and the effect of window ventilation in severe weather if floors are heated is under examination. Part of the investigation is concerned with the measurement of moisture in wheat and the speed of transference of this moisture from one part of the stored wheat to another, a problem which bears directly on the preservation of wheat from mites.

The Division of Chemistry has now been divided into a Fundamental Branch and an Applied Chemistry Branch; when the new chemical engineering building in the latter Branch has been completed there will be provision for at least three pilot-plants. Industrial researches in progress include work on laundering and cleaning, and interesting results have been obtained on the use and action of detergents and on soil-removal problems. The preservation of fabrics against rot, use of organic rust inhibitors in metal priming paints, silver catalysts for the oxidation of ethylene to ethylene oxide, synthesis of organic compounds containing heavy hydrogen, the chemistry of acetylene, use of acetylene black in rubber compounding, the testing of leather products and plastics and a study of methods for determining carbon monoxide in low concentrations are among other investigations of the Applied Chemistry Branch. About a third of the work of the Division has been concerned with fundamental problems in organic chemistry, including alkaloid studies and synthesis, the kinetics of polymerization and the synthesis of methoxybutadiene, photochemistry, including mercury-photosensitized and other reactions of unsaturated compounds, surface chemistry, such as the electrical resistance and length-changes of activated carbon rods, and studies on macromolecules, and colloid chemistry, including the development of a new and simple film balance which is being used to investigate the properties of gaseous films of fatty acids.

In the Division of Applied Biology, the utilization of agricultural surpluses and wastes, and food investigations have been the two main fields of activity. Two new fermentations studied in the laboratory capable of giving high yields of butylene glycol, with glycerol or formic acid as secondary products, are ready for pilot-plant study. Cyclic methyl ethyl ketal, derived from butylene glycol, shows promise as a blending agent for motor fuels, and aqueous solutions of *l*-butylene glycol appear to be satisfactory anti-freeze substances. A method of separating starch from gluten has been developed, and investigations commenced on the manufacture of wheat syrup. Food investigations during the War were directed almost entirely to the problems involved in the transport of perishable goods to Great Britain, work on egg products being particularly important. Quality-testing methods for use on canned poultry were revised, and it is expected that a plant based on the investigations on Irish moss as a substitute for the agar used in canned meats will shortly come into operation. Many nutritional problems were studied during the War at the request of the Armed Services. Co-operative studies with the Ontario Research Foundation and the Associate Committee on Grain Research were continued on the processing and treatment of domestic oils for edible purposes, and it was found that isolinoleic acid is not the only cause of flavour reversion in linseed oil shortenings. These studies are being continued in an effort to find means of preventing such reversion.

ARTIFICIAL CULTURES IN THE CHICK EMBRYO

"CULTIVATION of Viruses and Rickettsiæ in the Chick Embryo", by W. I. B. Beveridge and F. M. Burnet (*Med. Res. Coun. Spec. Rep. Ser.*, No. 256, 1946. H.M. Stationery Office, 2s. net), is a successor to a previous monograph by Dr. F. M. Burnet published in 1936. The method of growing viruses in the chorioallantoic membranes of the fertile hen's egg was at that time only just beginning. The pioneers of this method have been Burnet in Australia, where so much of this kind of work has been done, and Goodpasture in the United States. The development of the method has been so remarkable that the original technique of inoculating the chorioallantoic membrane is now supplemented by inoculation of the allantoic or amniotic cavities, of the yolk sac, of the veins of the membranes and even of some organs of the embryo itself.

In the present report these techniques are described and the particular difficulties of each are discussed. Important, too, are the notes on appearances in the egg which may be mistaken for lesions produced by viruses, and on bacterial contaminants which occur in some eggs. Useful also are the photographs and diagrams. The advantages of this technique for certain purposes include avoidance of the expense and time involved in the maintenance of small animals, the virtual elimination of cross-infection and the fact that the method gives greater yields of some viruses than can be obtained from any other source. Hen's egg is used, for example, for the production of typhus vaccines, and it can provide enormous yields of influenza virus. The method is also used for the preparation of vaccines against yellow fever and equine encephalomyelitis. A bacteriologically sterile vaccine against smallpox can be made using hen's eggs, but this method has not been widely used. Fertile eggs are also used as sources of certain diagnostic agents, such as Frei antigen, and the reagents needed for Hirst's hæmagglutinin reactions which can be used for the quantitative study of influenza viruses and their antisera.

Dr. Burnet is now director of the Walter and Eliza Hall Institute, Melbourne, where he has worked with Dr. Beveridge and others. This is surely a striking instance of the value in this field of collaboration of a medical man and a veterinarian. Everyone who works with viruses will find this report indispensable. Its thirteen pages of references to work on every aspect of this technique and its uses are by themselves worth more than the very moderate price charged for the whole monograph.

UNIVERSITY LIBRARY SERVICE IN SOUTH AFRICA

THE inaugural address "The University Library, its Function and Potentialities", delivered by Dr. H. Coblans, librarian of Natal University College, Durban, on September 2, 1946 (Pp. 16. Durban: Natal University College), surveys the university library rather from the technical point of view of the librarian himself than from the wider angle of Bruce Truscot in "Red Brick University", and as he is also largely concerned with conditions in South Africa his address may disappoint some whom its title attracts. Dr. Coblans emphasizes the necessity of co-operation and co-ordination in scientific bibliographic service, and looks to the United Nations Educational, Scientific and Cultural Organisation for developments in that direction, urging incidentally the establishment in South Africa of at least one national centre corresponding with the Science Library in London. He recognizes that inclusive documentation may involve radical changes in existing bibliographical methods; but for the research worker, the technologist and the administrator, he considers the key tool should still be the abstract journal.

Dr. Coblans urges the development in South Africa of an inter-library loan system on the lines of that of the National Central Library in Britain, and the development of the essential Union Catalogue as well as the completion of Freer's "Catalogue of Union Periodicals". Directories of library resources, including special collections in industrial laboratories, a greater measure of co-operation at the level of uniform library techniques and standardization, the allocation of subject fields for intensive specialization by particular libraries, the use of microfilm to eliminate some of the huge gaps in South African holdings of scientific and technical periodicals, and to rescue important Africana in a state of rapid deterioration are among his concrete suggestions for improving bibliographic conditions in South Africa. Government support or subsidy and central organisation are also needed. The Council for Education, Sociological and Humanistic Research formed early last year has among its objects the promotion of library services and the provision of information services as well as assistance in the publication of results and other materials likely to be valuable for research.

Dr. Coblans then proceeds to discuss the informative rather than the distributive functions of the university, its work not merely in providing research materials for the scholar but also in bringing knowledge to the service of industry, municipal planning, health and social services. He regards it as the university librarian's task to provide the bibliographies needed, to guide inquirers to the best sources, to integrate and correlate the material. The librarian must know where and how to look, and much higher standards of education and of subject-specialization are accordingly demanded in library staff, while provision of the specialized information equally demands adequate provision of library tools in the way of catalogues, classification schemes and the like. Dr. Coblans sees, too, the library as an integrating influence, seeking to overcome departmental exclusiveness and over-specialization; and in recognizing the educational value of the new mediums such as films, he refers pointedly to factors which have obstructed the use of educational films in South Africa.

In conclusion, returning to the gaps in South African records and bibliographical tools, Dr. Coblans pleads for more comprehensive subject indexes to South African periodicals, newspapers and Government publications, for regular abstracts of research papers published in South Africa, for a register of all South African learned and technical societies and a directory of special collections; and he suggests that the four libraries in Natal University College should form a unit for bibliographical and information service to the province of Natal and the eastern seaboard and ultimately develop a university press.

FUNDAMENTALS OF INCREASED PRODUCTIVITY

THE "Statement on the Economic Considerations Affecting Relations between Employers and Workers", which was issued as a White Paper in January (Cmd. 7018. H.M. Stationery Office. 2*d.* net), followed hard on a *Planning* broadsheet, "Men, Management and Machines", which hammered out the same imperative need for a higher output from each man and woman. Whereas, however, the White Paper gives no hint as to how this increase in productivity is to be secured, the broadsheet makes some concrete suggestions, and presses implications of the present man-power situation on which Lord Beveridge touched nearly three years ago in a chapter of his book, "Full Employment in a Free Society". The White Paper, in fact, derives its importance from the open admission by the Government, endorsed by both sides of the National Joint Advisory Council, of the extremely serious economic position of Great Britain. It is a clear and forcefully written statement of facts that neither the Government nor the trade unions have hitherto cared to admit.

The gist of the White Paper is easily summarized. Most of its arguments, in fact, have been pressed by every impartial commentator for the last eighteen months. We have for the last seven years "deliberately distorted and unbalanced our economic system, suffered the loss and permitted the depreciation of our capital resources, sold at least half of our external capital assets and gone into debt abroad. . . . This country is still running into debt abroad. Each month our balance of overseas payments is still unfavourable. Nevertheless, since the end of the war this country has proceeded rapidly to establish schemes of social improvements in the way of a housing programme and improved educational system, comprehensive old age, unemployment and health insurance systems and medical and other services". Moreover, the output of consumer goods from domestic industries is still inadequate, and until the output of British industry is considerably increased there is bound to be some fear of our ability to maintain the stability of prices and the orderliness within our industrial system which have characterized Great Britain throughout all the difficulties of the War.

The over-riding factor is the shortage of man-power. The fourteen industries specified, including coal-mining, all the textile industries, several metal-working, the clothing, footwear, furniture, paper and printing industries, needed in November 1946 a further 657,000 workers, or an increase of twenty-two per cent, to regain their total of mid-1939. There is no source from which all this additional labour can be drawn ; on the contrary, the impending raising of the school-leaving age will reduce the total labour force by 370,000 juveniles. Furthermore, while our total working population was about 20,324,000 in November 1946, or about 570,000 more than at mid-1939, this includes 4,985,000 in the Forces and Auxiliary Services, Government services, fire and police services, the professions, entertainment and sport, leaving a balance of 241,000 smaller than in 1939; and the total is expected to fall to the pre-war level by 1948 owing to the fall in birth-rate and the further raising of the school-leaving age. Thus only an increase in output per head can provide an increased supply of goods from home industry and prevent a fall in the flow of imports as soon as the dollar loans are spent. The threat of inflation will remain while only £6,000 million of consumer goods and services face £7,000 million of incomes.

There is clear warning that without high production full employment itself is endangered, and that whether the standard of living can be improved depends on the output and efficiency of all our industries and essential services. The Government affirms its intention of maintaining control and ensuring that no unregulated increase occurs in the prices of essential goods and services; but it places fairly on the shoulders of both sides of industry the responsibility for steadying the costs of production, manning the essential industries and stepping up production until we have struck a balance between total demand and total supply.

In effect, the White Paper is an appeal, issued by the Government, and endorsed both by employers and by the trades unions. The *Planning* broadsheet shows a much clearer grasp of the magnitude and implications of the problem, and indicates some of the lines which Government policy must take, even at the cost of a break with past practice. It indicates rather more precisely the magnitude of our task in the production of capital goods and consumers' durable goods in quantities sufficient to meet arrears due to six years of war and replacements of material destroyed, including, for example, the provision of 750,000 new dwellings to meet immediate requirements, before starting on the extra three millions needed in the next ten or twelve years. Furthermore, the broadsheet directs attention to our commitments in Germany, where our joint responsibility in effect involves subsidizing for some time to come an additional population of about twenty-two millions.

On the labour force, *Planning* makes some pertinent comments. Our working population has increased since 1939 by about 3·3 per cent, solely in the number of women workers, and since the total population has increased by about the same proportion, the increase is not of itself likely to raise real income per head of population. Moreover, changes impending in our age-structure are likely to make for lower, rather than higher, total output. Hours of work are often shorter than before the War; and the increase in the number of paid workers not only necessitates, and may help to produce, an increase in output, but also increases the demand for labour in the transport, catering and entertainments industries.

On this question of deployment of the labour and mobility, *Planning* is much more realistic than the White Paper; and in the face of the arguments put forward it will be difficult to justify claims for shorter working hours as in the public interest. The corollary to the forty-hour week of an even greater increase in output per man-hour is driven home; and in view of some conflicting evidence it might be well worth while for some objective inquiry to be put in hand on that point, as was suggested by the Chief Inspector of Factories when he observed in his 1944 report that much research was still needed before the relation of output to hours of work was fully known, and that close scientific study of these and kindred problems would amply repay the time and effort involved. Even more realistically, the *Planning* broadsheet proceeds to inquire into actual performance and, to say the least, there is little evidence to be adduced that the productivity of industry has increased at all since before the War. Data in some industries are admittedly scanty; but the broadsheet states that in the coal, cotton, iron and steel and even the building industries, output per man-hour is appreciably lower than before the War.

The most valuable section of the broadsheet is the analysis of some of the causes which follows the discussion of performance. Except for coal-mining, where absenteeism may account for nearly half the drop in output per worker since 1939, the proportion said to be attributable to absenteeism and reduced physical effort is probably much less than half. Some of the causes may indeed well be temporary. Staleness, resentment at loss of high war-time earnings, lack of goods in the shops, housing and other family troubles precipitated by the end of the War, and taxation of wages under the 'pay-as-you-earn' system are obvious factors militating against regular attendance and maximum physical effort. Other causes of low productivity, which may also be temporary apart from those obvious difficulties of production planning, lay-out, training and re-tooling involved in re-conversion, may be seen in the shifting of the labour force, more than one third of which has changed jobs since the War, the acquisition of new peace-time skills, the poor condition of plant in many factories, and the difficulty under present conditions of planning production so that output is high and steady.

While, apparently, these are temporary factors which should gradually disappear, they are too interlocked to warrant excessive optimism; and some at least can be eliminated more by Government policy than by any other means. That is true of taxation and to some extent of raw materials and components, which are probably the greatest single cause of low productivity in manufacturing industry. The broadsheet quotes from a pointed article in the *Board of Trade Journal* of November 23, 1946, which shows that there is scarcely a major industry which is not, directly or indirectly, a consumer of raw materials listed as likely to be insufficient to meet demand during the next twelve months. The position is confirmed by the *Monthly Digest of Statistics* for November, and on top of all this there is the problem of fuel, the importance of which has recently been suddenly—and unnecessarily suddenly—brought home to everyone in the British Isles.

Taking a long view and ignoring short-term adjustments, industry itself could increase output per worker in three ways which are to some extent interdependent: by more regular attendance and increased industry on the part of workers; by increased mechanization and more efficient machines and tools; and by better organisation and management. The first of these is essentially a question of improved morale, which usually will depend on a better understanding brought about by improvements in working conditions, involving the persuasion by the actions and attitude of management, rather than by official propaganda, that production is indeed a common task. It is here that contributions such as those of Dr. Mayo in his "The Social Problems of an Industrial Civilisation" are so important; for as *Planning* points out, concrete improvements in working conditions in themselves are not enough—and indeed amenities can be provided at too great a cost both in money and labour.

As *Planning* observes, the essence of management is getting people to do things, and for this it is necessary to understand people and to treat them properly. Special stress is laid in this broadsheet on two particular qualities: a sense of partnership with labour and a sense of service to the community; and, in referring to the value of joint consultation, the importance of giving the worker adequate information is stressed. That is endorsed by all the experience cited by Dr. Mayo, and the broadsheet once again emphasizes the vital responsibility of management in this field of human relations, and also that industrial management has its own contribution to make towards improving the relations between industry and Government.

Such considerations alone would emphasize the importance of the British Institute of Management, the composition of the Council of which has recently been announced. The association with this new enterprise of such men as Sir Clive Baillieu, Mr. C. G. Renold, Dr. J. E. Myers, Lieut.-Colonel L. Urwick, Sir Archibald McKinstry, Sir George Schuster and Mr. T. G. Rose gives every reason for confidence that the Institute will indeed raise the standard of management by helping to provide the right men with the right training and ideas. But as *Planning* pertinently observes, first-class recruits will not be found, nor will our present industrial leaders give of their best, while every manager is liable to indiscriminate political denigration—to be stigmatized by one side as a mercenary exploiter if he works for private enterprise, and by the other as an incompetent bureaucrat if he works in a nationalized industry.

Even from this brief survey, it is clear that there are several directions in which Government policy and action should and must reinforce the exhortations of the White Paper and whatever industry itself can do on either side. In the first place, it is primarily by Government action that the total labour force can be increased. The broadsheet refers to the importance of large-scale selective immigration, and powerful pleas have already been voiced for a deliberate policy of recruiting foreign workers for agriculture and for the mines. In particular, Prof. L. Robbins has argued convincingly for the use of an extra 100,000 such workers in the coal mines of Britain.

Nor is this the only way in which Government action could help. Taxation policy could be revised so as to invite the return of married women to industry, and intelligently administered pension schemes would encourage the able-bodied to continue at work even if only part-time. Taxation policy might also play a big part in increasing incentives to work; indeed, the desperate need for more production is sufficient reason for a critical review of the whole direct taxation system, and particularly that of 'pay-as-you-earn', from the point of view of incentives. Closely akin is the formulation of a consistent wage policy in which payment by results has an effective place, while finally the Government could, and should, overhaul the whole apparatus of economic control through one authority above the departmental level and competent to abolish those controls the usefulness of which is outweighed by the resources of time and labour they absorb, and to co-ordinate and simplify those that remain.

Such a review could undoubtedly make a direct contribution to the efficiency and pace of production, and would also be of value indirectly for its psychological effect on incentives. Equally, however, it is incumbent on the Government to review closely its whole use of man-power in the Services and to see that Great Britain's commitments are in keeping with her resources. That point was well raised in a House of Lords debate on January 29, which not only questioned whether we had the resources to maintain indefinitely a strong navy as well as a standing army of approaching a million, particularly in view of the declining numbers of young men reaching the age of eighteen each year, but also directed attention to the possibility of the Colonial territories supplying man-power necessary for overseas stations.

Both Prof. H. J. Laski and Lord Beveridge have pointed to the new functions which the trade unions and other professional organisations have to perform in conditions of full employment, and recent unofficial strikes emphasize the necessity for early and close attention to such matters as incentives, public relations, education and training, and the whole internal structure and organisation of the trade unions; this is necessary to enable the trade unions to make the great contribution which with wise leaders in close touch with the membership they undoubtedly could give to the well-being of a free society. As their defensive role diminishes in importance, so their constructive, positive contribution becomes potentially greater and more important. Prof. J. Jewkes has pointed out that acceptance of the policy of full employment will necessitate hard thinking by the trade unions regarding their future policy, and he suggests that such thinking might well start with a purely objective analysis of their past procedure. Indeed, if wage differentials are to be used to effect redistribution of labour, an examination of past practice is the basis for a decision as to the extent and speed at which such redistribution is possible.

No matter how wise and sound may be the Government policy and proposals for increasing productivity, a high degree of courage and skill will be demanded of the Government in bringing the public to understand and accept measures which, in some quarters and at some times, are bound to be unpalatable. For this reason, the White Paper is a call to every unprejudiced citizen to help the creation of a sound and informed public opinion on the matter, and to see that criticism of Government policy is both fair and responsible. That is essential if fresh incentives are to be found and industrial discipline maintained in the new conditions of full employment by a further change in the status of the work-people and by their assumption of a larger share in industrial management. Full employment, as Lord Beveridge has pointed out, ultimately depends on how private citizens use their liberties.

THE BRONZE ART OF ANCIENT CHINA

A Descriptive and Illustrative Catalogue of Chinese Bronzes acquired during the Administration of John Ellerton Lodge

Compiled by the Staff of the Freer Gallery of Art. (Smithsonian Institution Publication 3805: Freer Gallery of Art Oriental Studies No. 3.) Pp. v+108+50 plates. (Washington, D.C.: Government Printing Office, 1946.)

IT is probable that anyone who came in contact with John Ellerton Lodge will be left with a strong impression of a man with a great sense of quality—quality of conception as well as of execution—as is suggested in the preface to the volume descriptive of Chinese bronzes added to the collection of the Freer Gallery during the twenty-two years that he was director, from its first year as a public institution until his death in 1942. This volume is designed as a memorial to the man and a record of his work; it contains a few notes from his hand, but these were not written for publication and are little more than memoranda. It is the collections themselves and in particular the fifty-six archaic Chinese bronzes here reproduced in large-scale photographs which are the true monument; but even they will be touched by a finer light for those who can recall Lodge and his appreciation. They will value the portrait included in this catalogue.

A brief introduction of four pages is prefixed to the volume by Mr. A. E. Wenley, surveying the present state of the study of Chinese bronzes and taking a cautious view of the position reached in interpreting the historical inscriptions as material for dating and also of the stylistic sequences proposed by such authorities as Karlgren and Jung Keng. While recognizing that the work done by these scholars in the classification of the decoration "is most important and contains much of the truth", he adds justly that our present knowledge of the subject is still inconclusive, and the bulk of the scientific archæological work is still to be done. He and his collaborator, J. A. Pope, have, therefore, only attempted a division of the Pre-Han Bronzes into Shang, Chou, and late Chou, and have regarded their task as "telling something about individual pieces"; but this, of course, does involve some general principles, though the self-denying method adopted prevents the authors from explaining what these are. What, for example, in the general quality and treatment of the Kuei on Plate XXVIII do they hold must strongly suggest a date later than Shang?

The notes given beneath the descriptions of the pieces are for the most part concerned with the inscriptions; but parallels for the decoration are sometimes adduced and declared to be characteristic of this or that period. This dry objective treatment is rather characteristic of the Chinese approach to the subject; but some of Lodge's own notes treat more of the structure and form of the vessels, as of Nos. 13 and 14, and show a confident sense of style as a criterion of period. But they are equally notable for their careful observation of significant detail. The long and important inscription on the covered vessel fang-i (Plates XXI and XXII) is discussed at some length by Mr. Wenley, with reference also to Sir Neil Malcolm's well-known inscribed Kuei and to Chinese controversialists; but the important fact about both vessels is that these inscriptions are generally agreed to refer them to the eleventh century B.C., early in the Chou Dynasty. They show a baroque profile, and it is noticeable that the vessels assigned by the authors to earlier dates show less relief. Though this fang-i does not bear the name Ch'en Ch'en included in the inscription, it is associated with a group which does, and is said to have formed part of a find of about thirty-five ritual vessels at Lo-yang in Honan. Mr. Wenley points out that if the whole group is to be assigned to the same period (which must be the eleventh century B.C.), then "a considerable change must be forthcoming in methods of dating on stylistic grounds alone"; for the variations are great. But this does not altogether vitiate a stylistic basis for the chronology of each type of vessel, which alone seems a scholarly line to follow. There is, however, much value in the remark made by Mr. Wenley, that geographical factors are likely to differentiate styles as well as the time element.

Several of the vessels here published are of very rare, or in our present knowledge unique, shapes, such as the Huo with cover in the form of a human face with bottle-shaped horns, and the pair of tigers said to have been found in Shensi, apparently some kind of incense burners. Heading the mirrors is an interesting late Chou example with bird decoration from J. H. Cox's excavations at Ch'ang-sha in Hunan. The type is recognized as of Shou-chow, and though this is almost four hundred miles away, Mr. Pope points out that both places were within the confines of the great 'extra-China' State of Ch'u in the third century B.C. Another very interesting mirror, Plate XXXVII, is extensively inlaid with a gold and silver design of entwined dragons, characteristic of the Warring States period. The technical difficulty involved in this kind of decoration on a mirror has been overcome by setting the true mirror of speculum metal in a case of ordinary bronze. Various types of inscribed Han mirrors are represented by examples in remarkable preservation, the rarest being No. 39.38, which is decorated with alternate masks of dragons and tigers, and dated A.D. 174.

The ritual weapons illustrated are a remarkable group, there being no less than five inlaid with turquoise, and of these three have jade blades. The ceremonial 'Sickle' is the most extraordinary of all. It measures nearly 14 in. in length and may well originally have had a wooden handle inserted between the butt and the haft. The position of the blade seems scarcely to justify the name assigned to it, and it seems better to regard it as an example of ritual Ko similar to a number of others of which the jade blades only have survived, though admittedly not exactly of the form here found. Eleven of the weapons illustrated come from a group of twelve acquired with a romantic story of their discovery at Hsun-hsien, Honan, in 1931. Whatever the truth of the story, the fact remains that one here reproduced on Plate XLVII is inscribed with the name Marquis K'ang, which may well be the same name as that occurring on General Malcolm's Kuei which, as noted above, can be assigned to the eleventh century B.C. A feature of these weapons is the presence on three of them of figures or heads of monsters which in two cases are engulfing human figures. This would connect them with the well-known pair of bronze vessels with a similar motif in the round which were exhibited together at Burlington House in 1935–36. Its true significance has still to be explained.

The volume contains a bibliography of ninety-four publications, mainly recent, several of which do not seem to have yet reached Great Britain. It provides just the material which is required at the present stage of the study of archaic Chinese bronzes, and the authors can feel that it will stand the test of time and so be a lasting memorial to J. E. Lodge. It is to be hoped that it may be followed by similar volumes dealing with the other principal acquisitions which he made in the Departments of Persian and Chinese Painting, and Indian and Chinese Sculpture, including jade, of the Freer Galleries. They should be sure of a warm welcome not only from scholars, but also from all lovers of the art of the East, of which Lodge was such a discriminating judge.

BASIL GRAY

A MERRILL FESTSCHRIFT

Merrilleana

A Selection from the General Writings of Prof. Elmer Drew Merrill. (Chronica Botanica, Vol. 10, No. 3–4.) Pp. 127+394. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1946.) 4 dollars.

DR. E. D. MERRILL was born at East Auburn, a suburb in Auburn, Maine, on October 15, 1876. In the seventy years of his life he has made such contributions to the study of botany that the editor of *Chronica Botanica* records his being introduced, to Swedish botanists visiting Harvard, as the American Linnæus. His first botanical paper appeared in 1899, and the mere list of his publications (the vast majority strictly botanical, and including some still in the press) occupies thirteen and a half octavo pages.

The present work is a happy gesture of friendship to Dr. Merrill in the year of his seventieth birthday and of his retirement from the directorship of the Arnold Arboretum. In addition to a chronological list of important events in his life and another of his publications, there is reprinted a selection from the more generally interesting of his works, mainly on taxonomy, phytogeography, and economic botany.

Merrill's main researches have been connected with the flora of Malaysia and especially with that of the Philippines. His earliest botanical papers dealt with North American plants. With his appointment in 1902 as botanist to the Bureau of Agriculture and Forestry, Manila, began his connexion with the flora of the Philippine Islands. Among many other activities, he initiated the herbarium of the Bureau of Science, Manila, the first specimens being those collected by him in 1902. Twenty years later the herbarium contained 275,000 mounted specimens. It is one of the tragedies of the Second World War that this fine collection was entirely destroyed in 1945 during the re-occupation of Manila in the final phases of the Japanese defeat. All taxonomists must sympathize with Dr. Merrill in his feelings of personal loss. It is no doubt some consolation to him, and to taxonomists generally, that thanks to his methods, and to his generosity, so much material was collected for duplicate sets which were distributed to other botanical institutions. Typification and the settling of other botanical problems necessitating re-examination of specimens is thus going to be a much easier task than it might otherwise have been. In this, as in other respects, taxonomists might well follow Dr. Merrill's example.

On the whole, a judicious selection has been made of papers, or extracts, for reprinting. One misses an example of Merrill's more strictly taxonomic work and would have welcomed at least one paper to illustrate his precise, lucid and well-balanced style in preparing descriptions. Of the twenty-three reprints, those likely to be of widest interest are the ones connected with the plant geography of Malaysia and with the distribution of economic plants. It is obvious in reading or re-reading these contributions how Merrill avoids accepting any hypothesis, more or less newly put forward, as an explanation of all problems connected with the distribution of plants. Again and again he shows his caution by reminding his readers how incomplete is our knowledge of the flora and vegetation of these wide-flung tropical lands. In dealing with cultivated plants he adversely criticizes the extreme diffusionist hypothesis that civilization, and with it all important methods in agriculture and many crop plants, arose only once, and then in the Nile Valley. He is strongly against any belief in such supposed lost continental lands as Atlantis and Mu, and his arguments that all such conceptions should be subjected to the acid test of biological facts are typical of his well-reasoned outlook on major problems of plant history.

W. B. TURRILL

EXPERIMENTAL PHYSICS

Analytical Experimental Physics

By Prof. Harvey Brace Lemon and Assoc. Prof. Michael Ference, Jr. Revised edition. Pp. xvi+588. (Chicago: University of Chicago Press; London: Cambridge University Press, 1946.) 33*s*.

IN revising their work for its second edition, Profs. Lemon and Ference have added some eighteen pages of new material, including many of the more recent developments in electronics and nuclear physics. The betatron, the cavity magnetron, the general principles of radar, and nuclear fission, are among the new topics mentioned. The treatment of the triode has been expanded, though the only hint as to its rectifying action is contained in an artist's design at the head of Chapter 33, which looks like one of the relevant graphs.

It is stated that the first edition of the book was selected as one of the sixty best-designed text-books of 1943 by the American Institute of Graphic Arts.

It must be unusual to find a physics book appraised by this standard, but it is an unusually well-illustrated book. Sequences of photographs are used to follow the progress of demonstration experiments; these contain in themselves material for detailed study and some interesting work with pencil and paper. Only one sequence fails to deliver its message; plate 54 shows a series of cinematograph frames of progressive waves, numbered at irregular intervals, and when the key to the arrangement has been found it appears that the period of the waves is twice that stated in the captions.

The general excellence of the book was commended in these columns when it first appeared, and the upper limit of its possible usefulness to university students in Great Britain was then considered. The present reviewer, thinking of its adaptability for use in schools, finds that some two-thirds of the work covers the ground of the usual advanced courses in secondary schools, and that the remainder, while beyond this standard, is presented so clearly that a good pupil interested in reading beyond the limits of his syllabus could readily follow it. Some parts of the 'syllabus' work are done in less detail than is customary in Britain, but this is amply compensated by the full and careful treatment of experimental dynamics, physical optics, and wave motion. It can be recommended as a valuable addition to the school science library, and the paper and binding are such as to stand up to the constant hard use it would sustain in this capacity. G. R. NOAKES

PIEZOELECTRICITY

Piezoelectricity

An Introduction to the Theory and Applications of Electromechanical Phenomena in Crystals. By Prof. Walter Guyton Cady. (International Series in Pure and Applied Physics.) Pp. xxiii+806. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 9 dollars.

THE production of electric charges on certain crystals by the application of pressure was discovered by the brothers Curie in 1880. Until the First World War the phenomena were of scientific interest only, but with the researches of Langevin and Rutherford the use of ultrasonic waves became important in warfare at sea. Between the two Wars piezoelectricity became of great importance to radio in the control of frequency. During the Second World War millions of piezoelectric crystals were made for use in communications both by radio and by telephone. Corresponding to this intense industrial activity there has been a great development of the theoretical aspects of the subject.

The present volume has appeared at the end of one of the periods of most rapid development of the subject of piezoelectricity, and it is written by one who has contributed personally in large measure to that development. In its 806 pages it gives a comprehensive, detailed and reliable account of the subject, and it is at the same time a reference work and a text-book. It is mainly theoretical in treatment; few descriptions of apparatus occur, and the practical details of measurement are scanty. A few electrical circuits are given, but in general only the main features of these are mentioned.

The first seven chapters are concerned with fundamental theory of crystal elasticity, including vibrations in crystals, and the dielectric properties of crystals. One important feature of these chapters is the explicit formulation of the various elastic and dielectric properties for plates and bars of any arbitrary orientation. For those who have occasion to work in this field, these detailed tables will be of great help. Chapters 8–12 deal with fundamental piezoelectric theory. This is one of the most valuable parts of the book, for it compares in a most lucid manner the various theories which have been advanced. Coming, as it does, just after the recent intensive study of the Rochelle salt group of crystals, this section of the book is most welcome, as it puts into proper perspective the relation between the piezoelectric properties of the Seignette-electric and the quartz-like groups of crystals. Chapters 13–18 discuss piezoelectric resonators—the theory, an outline of the methods of manufacture, the influences of air-gaps, electrodes and special cuts both for quartz and other crystals. Chapter 19 is devoted to the piezoelectric oscillator. The next 140 pages, Chapters 20–27, are concerned with the Seignette-electric crystals. The properties of Rochelle salt are exhaustively described on the basis of a critical survey of the literature. This is a most involved subject, largely because so much of the original work was done without a full appreciation of all the factors which affect the results, and the new reader will be grateful for this clear analysis. The last five chapters deal with certain applications of the phenomena of piezoelectricity, pyroelectricity, certain optical effects in crystals, a sketch of the atomic theory of piezoelectricity and a brief account of ferromagnetism designed to show its relation to the properties of the Seignette-electric crystals.

In the introductory chapter on crystallography there are a few points which might have been better expressed. On p. 15 a polar axis is defined as one "having at its two ends faces of different forms, with different numerical indices". This unqualified definition would not be accepted by crystallographers. Similarly, the statement "such vectorial effects as pyro- and piezoelectricity are found only with crystals having polar axes" is scarcely consistent with the piezoelectric character of class (222). It is also unfortunate that although the Hermann-Mauguin notation is mentioned in the introduction, it is not used in the text. Giving numbers to the crystal classes instead of the now accepted international symbols is a retrograde step. On p. 16 the statement "Two opposite vertices of a rhombohedron lie on the trigonal axis, thus forming a three-sided pyramid at each end of the crystal" will be confusing to the student who has been taught to distinguish between rhombohedra and pyramids as separate forms. On p. 34 the definition of a stereographic projection appears to exclude the possibility of points occurring outside the primitive circle. Crystallographers will also be surprised to learn on p. 36, "If the stereographic projection is desired for a face belonging to a hexagonal or trigonal crystal, for which the indices are given according to the Miller or the Bravais system, it is necessary first to calculate the relative intercepts of the face on the three orthogonal axes".

These relatively trivial criticisms would be inappropriate in reviewing such a great work were it not that a second edition will almost certainly be called for soon. In conclusion, it would be fair to say that this book does for the subject of piezoelectricity what Voigt's "Lehrbuch" did for the whole subject of crystal physics. W. A. WOOSTER

WHAT CHEMISTRY OWES TO X-RAYS*

By Dr. KATHLEEN LONSDALE, F.R.S.

In the nineteenth century, the table of atomic weights and the periodic classification of the elements were obtained by classical chemical methods. In the twentieth century, X-ray methods have added to these, atomic numbers and atomic radii. The twin sciences of X-ray spectroscopy and X-ray crystallography were founded in 1912 by the famous von Laue experiment. By measuring the X-ray spectra of all the known elements from aluminium to gold, Moseley, in 1913, was able to show that each element could be assigned a number (not always in the order of the known atomic weights) which was later identified with the charge on the nucleus in the Rutherford–Bohr atom, or the number of extra-nuclear electrons in the neutral atom. But while the ideas of integral nuclear charge and of the *K*, *L*, *M*, etc., orbits of electrons were primarily due to investigations of X-ray spectra, the study of X-ray scattering by the rare gases has shown that the Bohr orbital model is inadequate, and has demonstrated the superiority of the Sommerfeld wave-mechanical model of the atom, with its statistical electron-density distribution and its range of energy states. Atomic structure is fundamental to chemistry.

X-ray spectroscopy and X-ray scattering combined have also given by far the most accurate value to date of Avogadro's number, $6{\cdot}0228 \pm 0{\cdot}0011 \times 10^{23}$, obtained by equating the wave-length of X-rays as measured with a ruled grating and with a crystal of known density and structure.

X-ray spectroscopy has provided analytical chemistry with a tool of great sensitiveness for the identification of individual elements, since each element gives a spectrum almost (although not quite) independent of its state of aggregation or of chemical combination, but in any case quite distinguishable from that of other elements. As little as 10^{-9} gm. of uranium can be detected by its X-ray spectrum. This X-ray method has led to the discovery and identification of new elements; some, like hafnium and rhenium, now isolated and accepted; others, like the natural element 93 (isotope of neptunium), detected by Mlle. Cauchois and her colleagues in certain tantalites and monazites, but still awaiting confirmation by other methods. The development of sensitive curved-crystal focusing spectrographs has enormously increased the possibilities of X-ray spectroscopy, which is not used in Great Britain as much as it should be, either in science or in industry.

The chemical action of X-rays is small but not unimportant. It is almost entirely due to direct ionization and to the production of further ionization and activation through photo-electrons. This is the case, for example, in the photographic action of X-rays, in the production of very pure water through the decomposition of organic impurity by prolonged irradiation, and in the action of X-rays on living tissue.

But the greatest debt owed by chemistry to X-rays comes from the fact that by means of X-ray crystallography the study of the constitution of matter has been extended to the solid state. One of the most important properties of the solid state is cohesion. It is a remarkable thing, but so familiar that we have ceased to wonder at it, that if we lift one end of a poker, which is a conglomerate of crystals, the other end comes up too. Newton remarked that it was the business of the philosopher to explain this property, which is not found in ordinary liquids or in gases, though liquids have a non-directed cohesion. We think of these directed, permanent forces as physical, but they are surely chemical too, for they are an essential part of the composition of the solid substance and are related to the nature of the chemical bonds between the atoms. Since the atoms are continually vibrating, the chemical bond is not even a static one, but is a constantly changing balance of attractive and repulsive forces. Ordinary methods of chemistry cannot be applied to the solid state, since dissolving, melting or vaporizing a substance destroys its solid character, and may completely change the molecular configuration or the nature of the inter-atomic bonds. The first X-ray crystal analyses by W. L. and W. H. Bragg heralded a new era in structural chemistry, an era in which the importance of atomic radii was first realized, although even now insufficiently realized by most chemists. It soon also became apparent that the former classification of bonds as being ionic or homopolar was entirely inadequate. Metallic and van der Waals bonds are chemical bonds, and bonds of intermediate character also exist. Moreover, X-ray analysis has shown that for many purposes structural architecture is of foremost importance, and exact chemical constitution a secondary refinement. These points will be illustrated by examples, although it is not always possible to separate them.

Chemists had thought of compounds, such as sodium chloride, as being formed by the combination of atoms of different kinds, one of which had lost an electron, the other having gained it, and the two together forming an ionic molecule. They could prove that the ions Na^+ and Cl^- exist in solution, but could only conjecture that they also occurred as such in the solid state. X-ray methods proved it; but showed at the same time that no individual molecule exists. The Na^+ ion in solid sodium chloride is surrounded octahedrally by six Cl^-, to none of which does it stand in any unique relationship. In losing an electron, the sodium atom, so to speak, sheds a skin, and then proceeds to surround itself by as many neighbours of the opposite sign as it can conveniently attract, bearing in mind their relative sizes and the mutual repulsion of the surrounding anions. The number of anions a cation succeeds in holding (its co-ordination number) depends mainly upon the cation to anion *radius ratio*. If the radius ratio is greater than 0·73 (that is, $\sqrt{3}-1$), there will probably be eight-fold (cubic) co-ordination, as in caesium chloride (CsCl). If it is between 0·73 and 0·41 (that is, $\sqrt{2}-1$), there will be six-fold (octahedral) co-ordination, as in sodium chloride (NaCl) or magnesium oxide (MgO). If it is less than 0·41 there will be four-fold (tetrahedral) co-ordination, as in beryllium oxide (BeO). The same principle may be illustrated in AX_2 compounds by the series calcium fluoride (CaF_2), with an 8 : 4 co-ordination ratio; magnesium fluoride (MgF_2), 6 : 3, and beryllium fluoride (BeF_2), 4 : 2; with decreasing cation size. Finite complex ions, such as CO_3^{2-} and $PtCl_6^{2-}$ can of course exist, but they obey similar structural rules. The relative unimportance of valency is nowhere more strikingly illustrated than in the random structures, such as $LiFeO_2$, where Li^+ and Fe^{3+} randomly occupy the cation positions in a rock-salt type of structure; or in the spinels, which may be either of the type AB_2O_4 (where the valencies $A + 2B$ add up to 8), or of the type $B(A, B)O_4$, in which A and B metal ions of different valencies randomly occupy equivalent positions. The actual existence of some compounds is dependent upon this size factor; $NaPO_3$ and Na_3PO_4 can both exist because P^{5+} is big enough to hold four O^{2-} ions around it; but N^{5+} is not, and therefore although $NaNO_3$ exists, Na_3NO_4 does not. Solid solution of one salt in another with which it is not isomorphous, for example, $MgCl_2$ in $LiCl$, can sometimes take place with formation of a *defect* structure, a structure in which there are vacant places. Here there must be considerable local disturbance of valency conditions. The fact that (in spite of the Law of Definite Proportions!) FeS may contain up to 55·5 atomic per cent, of sulphur atoms is also due to a defect of cations in the structure.

---

* Summary of lectures delivered at the Royal Institution on December 5 and 12, 1946.

When atoms are joined together by covalent bonds, molecules do exist. In fact, they need not be finite, but may be infinite in one, two or three directions (for example, tellurium, antimony and diamond). Such infinite molecules were unknown before X-rays revealed them. The molecules are held together by van der Waals forces, or by hydrogen or hydroxyl bonds, or by a measure of polarization. Bonds of a kind intermediate between the extreme ionic and covalent types not only exist, but also are most common. In the silicates, for example, the Si—O bond has 50 per cent ionic character. The study of the silicates by W. L. Bragg and his colleagues has written a new chapter in chemical history; it has, as the president of the Royal Society said recently, "transformed a chemical riddle into a system of simple and elegant architecture". In cases such as aluminium fluoride (AlF_3) and silicon fluoride (SiF_4), where an abrupt change of melting-point has been taken to mean an abrupt change from ionic to covalent binding, what is really involved is a change from an infinite lattice (all similar bonds) to a lattice of finite molecules (with strong interatomic, but weak intermolecular, bonds), the change being governed entirely by considerations of size.

Definite intermetallic compounds exist, as well as solid solutions. Chemistry now has to cover the whole field of metals and alloys. Hume-Rothery has shown that structure type in many alloys depends not on valency or chemical formula, but on the ratio of the number of free electrons to the number of atoms. This rule may be only approximate, but there does seem to be a marked analogy between the structure of some metals and of some defect ionic-compounds. Sodium, for example, consists of a body-centred cubic arrangement of positive metal ions, with about an equal number of electrons, free or nearly free to move, giving high thermal and electrical conductivity. The α-form of silver iodide consists of a body-centred cubic arrangement of negative iodine ions, with an equal number of positive silver ions forming an interstitial liquid, and giving a high ionic conductivity. There seems no good reason why the bonds should be regarded as chemical in one structure and not in the other. Interstitial solid solutions of small atoms in metal structures (for example, hydrogen in zirconium, carbon in iron) are of great industrial importance. The difference between a mixture, a solid solution and a compound is easily observable by X-rays. Each element or compound gives its own X-ray patterns, by means of which it can be identified. (Note the difference between chemical analysis through X-ray spectroscopy, which identifies the elements in a substance; and X-ray crystallography, which identifies the substance itself by comparison with a set of standards.) A mixture gives the patterns of both constituents; a solid solution gives an intermediate pattern, from which the proportions of each constituent can be found with an accuracy of 1 or 2 per cent. A different type of chemical analysis was that in which, by measurement of the positions and intensities of the powder lines from long-chain ketones, Shearer in 1922 deduced the lengths of the chains and the positions of the ketonic oxygens.

In the field of organic chemistry, the size and shape of the molecule, the arrangement of atoms in it and the nature of the inter-atomic bonds have always been of particular interest to chemists. The diamond and graphite structures were among the first to be determined, but even now they are not fully understood. It is not certain whether there is a concentration or defect of electrons between neighbouring carbon atoms in diamond, and some X-ray reflexions from some diamonds are not accounted for. The usual graphite structure holds for about 80 per cent of all specimens, natural and artificial; but there are other ways in which the hexagonal layer molecules can be stacked together. Graphite-potassium 'alloys' can be formed by the holding of potassium atoms between the layers; another argument for regarding the van der Waals forces as essentially chemical in nature. X-rays can explain why charcoal can adsorb gases so easily as to act as a catalyst in bringing reacting gases together, and why its adsorption is much increased at low temperatures. The first property is a question of the increase of surface when graphite is in a colloidal state, the second is that of a reduction of atomic vibration which otherwise hinders the entry of foreign atoms. In graphite the valency bonds are intermediate between single and double bonds, having a bond order 4/3. The binding in the layer molecules may alternatively be described as metallic. Measurements of diamagnetic anisotropy confirm that the electron orbits in the layers have exceptionally large areas. The shape of the benzene nucleus and the nature of the aromatic bonds have also been determined unequivocally by X-ray methods, without the use of any assumptions. In fact X-ray analysis, and careful Fourier determinations of electron density contours in particular, have provided an immense amount of evidence for the theory of resonance, or mesomerism. In aromatic substances, such as coronene, and in conjugated systems, such as sorbic acid, the lengths of the C—C bonds have been related to the bond order; and improved methods of three-dimensional Fourier syntheses are enabling such measurements to be made in structures where atoms would not be properly resolved in an ordinary two-dimensional Fourier projection. In aliphatic long-chain compounds such as paraffins or fatty acids, the C—C bonds are similar to those in diamond, and the carbon atoms are arranged in a plane zigzag at nearly the tetrahedral angle; but investigation of the links of the chain in polythene (where the effect of end-groups can be neglected) has shown that besides a large thermal motion normal (but not parallel) to the chain-length, there is an actual sideways spreading of the electron cloud; an effect which is confirmed by diamagnetic measurements. X-rays can therefore provide evidence of electron-cloud distortion in molecule formation, as well as giving a measure of thermal vibration in different directions for the various atoms in a molecule.

Another important chemical problem upon which X-ray methods have given much information is that of hydrogen- and hydroxyl-bond formation. Although X-ray analysis cannot in general locate hydrogen atoms, because of their low scattering power, hydrogen bonds can be detected because of their reduced length as compared with van der Waals bonds. The effect of replacing hydrogen by deuterium has been studied, and also the configuration of water of crystallization and adsorbed water. Water layers, held in position by residual forces, can increase the layer spacing of clays from 10 to 20 A., and some protein structures also contain considerable amounts of water. Such structures form special cases of compounds in which two different molecules crystallize together. Picryl iodide (tetragonal) and hexamethylbenzene (triclinic) crystallize together to form an orthorhombic, pseudo-hexagonal layer structure. The suggestion, by Fraenkel and Rudall, that insect cuticles consist of alternating monolayers of protein and polysaccharide, promises a wide field of investigation.

Many natural fibres give good and characteristic X-ray patterns, from which the size and shape of the fundamental unit of structure (a link in a high-polymer chain) can be determined, and also the size, shape and arrangement of the fibre crystallites, or micelles. Cellulose and alginic acid, linear proteins such as the fibroin of silk and the keratin of birds and reptiles have been studied. Although the X-ray patterns are comparatively poor, it is a very striking fact that stretched and unstretched wool, hair and horn on one hand give patterns which, as Astbury has pointed out, are almost identical with those of stretched and unstretched myosin on the other. In spite of their very different chemical constitution, their structural architecture is similar (compare $NaCl$, MgO and Li_2TiO_3; or many of the silicates). The visibly crystalline proteins, such as insulin and hæmoglobin, also show definite similarities of intramolecular structure. X-rays have shown that some of the globular proteins are just polypeptide chains folded in different ways, and that when unfolded (denatured) they form linear fibrous proteins of about the same density. An artificial wool prepared from ground-nuts was the outcome of chemical research based on such deductions from X-ray data. The peculiar mechanical properties of rubber, which resemble those of animal tissues, are a consequence of its molecular configuration, and the differences between rubber (*cis*-) and gutta-percha (*trans*-), both high polymers of isoprene, are being studied by X-ray methods.

Bernal has summed up the different stages in X-ray investigation of complex substances as being (1) identification; (2) measurement of molecular weight; (3) measurement of molecular symmetry; (4) measurement of molecular size and shape; (5) determination of position of substituent groups; (6) of each atom; (7) and of the electron density distribution throughout the solid. One may add also the changes in atomic and electronic configuration that take place with change of pressure, temperature and time. In the analysis and synthesis of a complicated substance such as penicillin, X-rays can be, and have been, invaluable in identifying and checking up on degradation products and on synthetically produced material. Exact measurements of molecular weight (density multiplied by volume of unit cell multiplied by Avogadro's number divided by number of molecules in unit cell) by X-ray methods have been used to correct wrong chemical formulæ and to determine amounts of water of crystallization. Molecular symmetry can distinguish, for example, between *cis*- and *trans*-isomers. The study of sterol derivatives by Bernal showed that the size and shape found by X-rays was quite inconsistent with the then accepted stereochemical formula, and led directly to the present formula which has been confirmed by both chemical and X-ray measurements. Bernal was also able to suggest, even without a complete analysis, just where substituent groups must go in order to explain the double-layer formation in many sterols, and the single layers that occur in the sex hormones.

In order to determine atomic positions completely, it is necessary first to have sufficient X-ray measurements, and then to interpret them. The interpretation is sometimes simplified either by putting a heavy atom into the molecule, or by comparing isomorphous compounds, in one of which there is a fairly heavy atom. The first method gave the structure of platinum phthalocyanine and of $Fe(CNCH_3)_6.Cl_2.3H_2O$ very directly. It was also successfully used in the X-ray analysis of the two cholesteryl iodide structures by Carlyle and Crowfoot, although these were much more difficult because the heavy iodine atoms were not in special positions. The analysis of the structure of penicillin (Crowfoot and Rogers-Low; Bunn and Turner-Jones; to be published) was achieved by comparing the two isomorphous potassium and rubidium salts with the related, but not isomorphous, sodium salt. It represents the technique of X-ray analysis used at its fullest power, both in regard to difficulty of experimental manipulation and of reasoned interpretation. In the case of complex chemical substances such as these, X-ray and chemical methods go hand in hand, each owing much to the other.

Finally, it is possible, by means of X-rays, to study the thermal vibrations of atoms and molecules, movements which are influenced by, and which throw light upon, the nature of the chemical bond. The partial breakdown of crystalline forces that occurs when atomic groups begin to rotate, or when statistical structures are formed in which groups, by assuming random orientations, simulate a higher symmetry than they actually possess, must correspond to very peculiar conditions in the chemical bond. There are also crystals which, although regular enough to give good X-ray diffraction, behave in many respects like liquids. A study of these may help to bridge the difficult gap between relatively simple chemical compounds and the complex substances that constitute living matter.

THE TOTAL SOLAR ECLIPSE OF MAY 20, 1947

By Prof. F. J. M. STRATTON, O.B.E.

THE first total eclipse of the sun after the conclusion of the recent World War will take place on May 20 next. The belt of totality passes from Santiago in Chile, where the sun will rise in eclipse, across the Argentine, with Cordoba close to the edge of the belt, Paraguay and Brazil, leaving South

America at Salvador; it then crosses the Atlantic without touching any islands, enters West Africa just south of Monrovia in Liberia, runs through the Ivory and Gold Coasts, Nigeria, the Cameroons, French Equatorial Africa, the Belgian Congo, Uganda and Kenya, passes just south of Nairobi, and leaves the East African coast just north of Mombasa, the sun setting in eclipse. The width of the track varies from about 80 miles at sunset and sunrise to about 110 miles in Brazil and West Africa.

The Atlantic coastal regions crossed by the belt of totality are both very cloudy, wet areas in May, and the best chances of success for astronomical observations would seem to be provided by the high lands of Brazil, which can be reached by rail and air, north and north-west of Rio de Janeiro. One British expedition, under the leadership of Dr. J. A. Carroll, is going to Araxa; the other members of the party are Dr. Alan Hunter and Dr. Alan Baxter. Their programme consists of observations of chromospheric line-widths by means of an echelon spectrograph, a study by means of an objective interferometer of possible motions in and of the corona, and an examination of the darkening towards the sun's limb in the infra-red. It is expected that a party consisting of Mr. Michie and Mr. Ivan Thomsen, sent by the New Zealand Government, will join the British party; also a party of Australian radio-physicists, who will carry out a radio-noise programme.

The possibility of securing observations from the air in the West African zone has been carefully considered; but in view of the type of aircraft available and the heavily cloudy conditions expected, it was felt that there was no chance of improving on the spectrographic results obtained from the air in Canada in 1945.

Not much information has yet been received of other expeditions. The Saltsjöbaden Observatory in Sweden is sending two parties under the general supervision of Dr. Öhman, one to Brazil and one to West Africa. The main object of the double expedition is geodetic, to gain information on the shape of the earth by comparing carefully timed observations at the two stations. But it may be taken for granted that Dr. Öhman's presence indicates that part of the programme will be connected with the problems of the polarization of the coronal light.

It may be assumed that the Cordoba Observatory will organise an expedition, but no details have yet been received. The National Geographic Society and the U.S. Army Air Force are sending a joint expedition to Bocayuva in the State of Minas Geraes, about 400 miles north of Rio de Janeiro. The altitude of the sun will be about 40°, the duration of totality 3 min. 50 sec. The programme comprises coronal photographs, including colour photographs, polarization of coronal light, spectra of the flash and corona; the temperature of the corona near the limb will be studied and the Einstein relativity effect will be looked for, though the field of stars is not favourable for this purpose. Changes in the ionosphere at successive contacts will be watched, and during the eclipse *radio-sondes* will be sent up and the Air Force will fly observation aeroplanes equipped with instruments. The most important instruments will be taken to South America by air. Dr. Lyman J. Briggs, recently director of the U.S. National Bureau of Standards and now chairman of the Research Committee of the National Geographic Society, will lead the party. Fifteen observers, including Dr. van Biesbroeck and Dr. Weaver, will form the eclipse party and will come from the U.S. Naval Research Laboratory, the National Bureau of Standards, Georgetown Observatory, Washington, Yerkes Observatory and Lick Observatory.

The eclipse will be invisible in Europe, save as a partial eclipse in the extreme south of Spain.

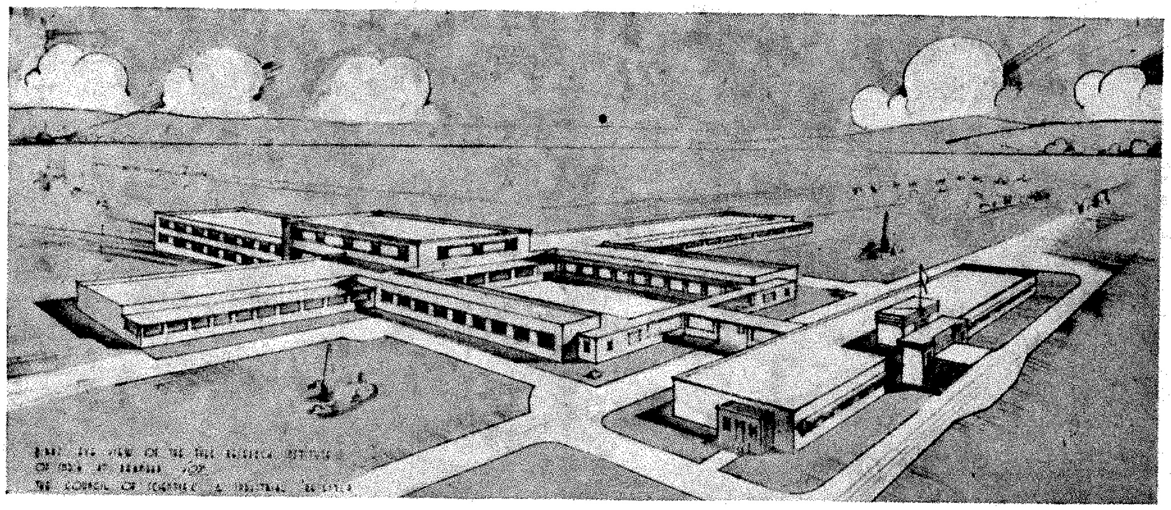
FUEL RESEARCH INSTITUTE OF INDIA

By Dr. J. W. WHITAKER
Director, Fuel Research Institute

THE Fuel Research Institute for India is being built in the Jharia Coalfield at Digwadih, some ten miles south of Dhanbad, and 170 miles north-west of Calcutta. The area of the site is 150 acres.

The work of the Institute will comprise technical investigations and research into the sampling, analysis and testing of fuels; combustion and furnaces; heat transference; coal carbonization; coal purification; briquetting; gasification; hydrocarbon synthesis and hydrogenation; tars and plastics; liquid fuels and internal combustion engine performance; smoke and atmospheric pollution. Fundamental research will not be neglected. Fuel technology, broadly speaking, is chemical engineering; it meets with the same problems in its field of action. Pure science is imperative: engineering technology is equally imperative, and economics must not be underrated.

India produces yearly about 25 million tons of coal valued at Rs. 30 crores at the pit-head. Her coal reserves have been estimated at some 65,000 million tons, but many seams are difficult to utilize economically. It is the main function of the Fuel Research Institute to ensure that this valuable supply of material be employed to the best advantage. At the same time, the properties and uses of all types of fuel will be studied, including petroleum, wood, charcoal, alcohol and gaseous fuels. There are, of course, a number of problems peculiar to Indian fuels. Thus in the coalfields of Bihar and Bengal, which are major coalfields, an important difference exists between Indian coals and those of Great Britain. In Britain most seams are relatively clean, or can be separated into clean and refuse bands. With Indian coals, however, the line of demarcation is seldom sharp. Frequently the clean coal has an ash content of 12–15 per cent or more—a feature attributable to the drift origin of the seams. These coals are difficult to purify by ordinary washing methods, a difficulty to be expected as the coal and foreign matter were originally deposited simultaneously as sediment from water. The coals in question are of the bituminous type, and many of the seams yield excellent coke with low sulphur content, in spite of the comparatively high content of ash. On the other hand, certain seams remain unworked because of still greater contamination with foreign matter. In other coalfields, for example, Assam, unusual difficulties are experienced because of abnormally high sulphur, present largely as organic sulphur and as sulphate. The ash content of these coals is low, the calorific value high; sulphur alone is the handicap.



ARCHITECT'S DRAWING OF THE FUEL RESEARCH INSTITUTE, INDIA

The problems of coal purification and processing are thus particularly important and require special attention.

Scope of Work

All departments of the Institute will co-operate in the conduct of schemes of research, but at the outset the following divisions are proposed: (1) Physical and Chemical Survey of coal resources (including field laboratories); (2) Carbonization and by-products (including colloids and rheology sections, tars and plastics); (3) Liquid Fuel Division (including hydrogenation, synthetic fuels, petroleum, alcohol, etc.); (4) Physics Division (including pyrometry, calorimetry, heat transference, X-ray and spectroscopy); (5) Gaseous Fuels Division (including combustion control); (6) Engineering Division (including preparation of coal for the market, boiler plant, etc.); (7) Library and Intelligence; (8) Administration and Office.

The present programme comprises a preliminary survey of the chief seams, including proximate and ultimate analyses, washability tests, ash analyses and tests, coking tests, carbonization assays, gasification tests, and investigations into tars. Subsequent work will include more detailed examination on the above lines and further researches into the utilization of the coals, either directly as fuels or indirectly as the products of carbonization, complete gasification, hydrogenation, and synthetic processes. Work will also be done on Indian oils and fuels not derived from coal, such as wood and alcohol. Pilot plant will be constructed as required.

Lay-out and Research Sections

It is expected that the construction and equipment of the laboratories and workshops will occupy two years. A third and fourth year will be devoted largely to the construction of plant. Broadly speaking, the lay-out is divisible into three main portions, namely, the administrative section, the laboratories and the technological block. Due to the climatic conditions, air-conditioning will be provided for the administrative and laboratory sections.

The General and Coal Survey Laboratories will include rooms for ash estimation, for ash fusion tests, and for research on refractories; inorganic chemical laboratories; rooms for high- and low-temperature assay, and coking and swelling tests; rooms for determination of moisture, volatile matter, carbon dioxide, etc., and for the ultimate analysis of coal; an inorganic analytical laboratory for determination of sulphur, phosphorus, arsenic, chlorine, etc.; calorimetry and balance rooms; preparation and solution rooms, and a small office.

For carbonization, by-products and liquid fuels the lay-out comprises a laboratory for special carbonization experiments; a routine laboratory for carbonization, blending and oxidation tests; an organic laboratory for work on liquid fuels; a physical chemistry laboratory for work on mineral oils and the like; preparation and balance rooms, and a small office.

In the Physical and Gas Research Subsections, rooms will be provided for X-ray control; pyrometer testing, ultra-violet and infra-red spectroscopy; gas analysis; combustion and gas research; a special gas research laboratory for fractionation of gases, thermal investigations, etc.; and a preparation room and office.

For special research, provision has been made for work in microscopy, coal petrography and related investigations; section-cutting and polishing; hydrogenation; rheological investigations and particle-size determination; research on colloidal fuels; electrical, magnetic and optical properties; chromatography and photo-chemical analysis; microanalysis, molecular research; hydrocarbon synthesis, and plastics research.

For coal preparation, equipment will be installed for making standard tests on the washability of coals. In addition, accommodation and apparatus will be provided for tests on commercial samples; and for special researches on methods of de-ashing of Indian coals, for example, by froth flotation. Rooms are also allocated for investigations into wetting and frothing and amalgamation agents with and without fine grinding, and for investigations into slurry problems in washeries, the stabilization and coal-cleaning media, etc. These laboratories will be near the technological block, within easy access of sampling, crushing and screening plants.

The Technological Block

The technological block will have the following facilities: (1) weighing, crushing, grinding, and sampling plant, and fine-grinding equipment; shatter test apparatus for coke; abrasion test apparatus for coke; screens; a room for the storage of samples for reference; (2) general stores; precision instrument shop; (3) general workshops; (4) room for electrical power distribution; (5) semi-technical carbonization ovens; (6) small gasification, hydrogenation and artificial oxidation plant; (7) boiler and pulverized fuel firing equipment; (8) vibrator screens for screen analysis on large-scale samples; and (9) small foundry.

Space is provided for boiler and other plant which may be required, for example, coke ovens, producer gas units, hydrogen generators, low-temperature carbonization plant, tar-hydrogenation plant, refineries, gas holders, Fischer–Tropsch units, and coal-washing plant.

A railway siding will be available for the technological block and the above plants in due course. Meanwhile, permission has been obtained to use the nearby railway siding of the Tata Iron and Steel Co.

Coal Survey Laboratories

To take stock of the basic supplies of fuel in India is but plain sense. Fuels provide the raw materials for heating and power generation and for numerous chemical industries, which in a planned economy require a degree of co-ordination. Fuels are essential to industries producing dyes, explosives, drugs, plastics, disinfectants and antiseptics; coal tars are of prime importance in highway construction; while in the manufacture of lime and cement, of bricks and refractories, of iron and steel, fuels are indispensable. Add to this that they provide usually the main source of power for all industries—generally through the medium of steam-raising plant—and their fundamental importance is unquestionable. Fuels, however, are a wasting or diminishing asset in contrast to water-power. Consequently reserves become of great significance. In India reserves of good coking coal are disconcertingly low, according to present statistics, reserves of iron ore of excellent quality being far in excess of the known available supplies of coal suitable for the manufacture of the requisite metallurgical coke. A policy of conservation for such coals may have to be adopted.

It is thus necessary at the outset to make a survey of the types of coal and the amounts available, and it is proposed to establish, as in Great Britain, coal survey laboratories in the major coalfields, staffed and equipped for the sampling and testing of fuels. Standard methods will be adopted wherever practicable. It is not the intention, however, to confine the functions of these laboratories to the assessment of resources, qualitative and quantitative. They will be encouraged to help in the numerous problems which arise in industry, whether fuel-producing or fuel-consuming. Moreover, should national policy so decide, these stations may also serve in the control of distribution and utilization of fuel. Meanwhile, their main function is the physical and chemical survey of the fuels available. Needless to say, in this work the Fuel Research Institute will co-operate closely with the Geological Survey and the Mines Department. The coal survey for the Jharia Coalfield will form part of the work of the Institute. The officers of the various survey stations will be trained at the Institute, and close liaison maintained between them and headquarters by such means as half-yearly conferences.

Staffing and Expenditure

The technical, administrative and artisan staff at the Institute will number between 100 and 200. The administrative staff will be of the order of 20–30; the technical staff will have 15–20 senior officers with 40–50 juniors, and an equal number of laboratory assistants and mechanics. Adequate unskilled labour has also been allowed for. Each of the field survey stations will carry a staff consisting of one or two senior officers, with 5–10 juniors, and a proportionate number of assistants for office and laboratory work. In some cases, unusually heavy charges have had to be anticipated for accommodation, transport, apparatus and chemicals, especially if the stations are remote from towns.

The annual expenditure of the Fuel Research Institute will be of the order of £100,000, excluding the expenditure on the field survey stations, which will vary with their number, but is expected to be of the order of £5,000 each. The capital cost of the central Institute and of the survey stations is of the same order as the annual expenditure, say £120,000 for the main Institute and £7,000 for a survey station.

The foundation stone of the Fuel Research Institute was laid by the Hon. Mr. C. H. Bhabha, Minister for Works, Mines and Power in the Interim National Government, on November 17, 1946.

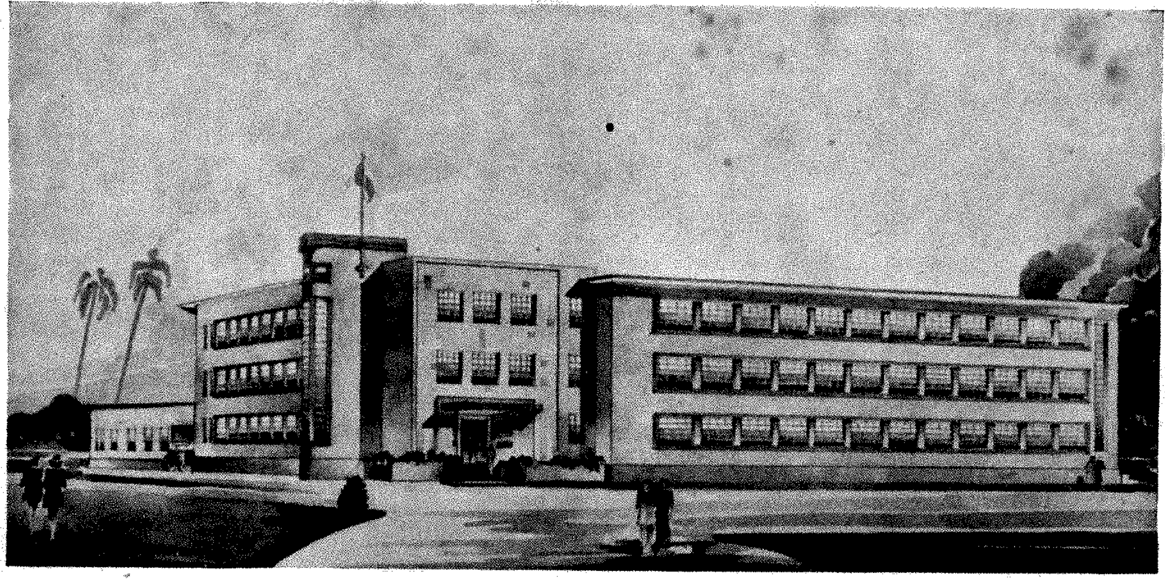
CENTRAL GLASS AND CERAMIC RESEARCH INSTITUTE, INDIA

By Y. P. VARSHNEY

Acting Officer-in-Charge, Central Glass and Ceramics Institute

THERE are few fields of industrial development in which scientific investigation has played, during the last twenty-five or thirty years, such a decisive part as in the glass and ceramic industries. Whereas in these industries spectacular developments have taken place in the industrially advanced countries of Europe and in America, conditions in India have remained comparatively static, although under the stress of war there has been some expansion.

Attention was directed to the unsatisfactory condition of the Indian glass industry and to the need for an Institute for training and research in glass technology by the Indian Industrial Commission so early as 1918, and this was further stressed in the report of the Indian Tariff Board on the glass industry in 1932. It was considered that the industry in India could not be expected to make satisfactory progress or make much headway without the aid of properly organised technological institutions, although the industry enjoys numerous advantages such as availability of raw materials, labour and a ready market within the country. The need for research was never felt so keenly both by the Government and the industry as during the War, when large and immediate supplies of glass and ceramic goods were required, and the Indian industry was hard put to meet the



ARCHITECT'S DRAWING OF THE CENTRAL GLASS AND CERAMIC RESEARCH INSTITUTE, INDIA

demand in respect of quantity and quality, as well as of variety. It was to fulfil this urgent need and to create an organisation for helping the glass and ceramic industries in the application of scientific methods that the Government of India, through the Council of Scientific and Industrial Research, decided to establish the Central Glass and Ceramic Research Institute.

The preliminary details for its establishment were worked out by a committee under the chairmanship of Sir S. S. Bhatnagar. A report embodying its proposals was submitted by the committee to the governing body of the Council in August 1944, and on the basis of its recommendations the Council decided (*a*) that the Institute be located at Calcutta, which is an important centre of glass and ceramic industries in India, and which offers many other advantages for the work and growth of an institution of this nature, and (*b*) that a sum of twelve lacs of rupees be provided for the capital expenditure of the Institute.

Site and Buildings

The site selected for the Institute is in one of the southern suburbs of Calcutta in comparatively quiet and open surroundings. It measures approximately 650 ft. × 440 ft., the shorter side on the west giving the road frontage; it is nearly seven acres in area. The major part of this plot is expected to be taken up by the Institute buildings, but a small portion may be utilized for building residential quarters for some of the senior staff, if this is considered necessary at a later stage.

The buildings of the Institute have been designed in an L-shaped plan and will consist of two sections, namely, a main building which is ultimately intended to be a three-storeyed structure, although only two storeys may be built at present; and the technological block, which is single-storeyed and has, for the greater part, a north-light roof.

Such a division was considered desirable in order that laboratories for precision work, library, museum, offices, etc., could be located in the main building, while furnaces, workshop, machines for raw material treatment, etc., and large testing units, the operation of which is of necessity attended by considerable vibrations and noise, could be placed in the technological block. However, these two sections, though distinct, are to be close together and connected so as not to hamper in any way the progress of co-ordinated operations being simultaneously carried out in both of them.

The main building, with a floor area of about 17,500 sq. ft. on each floor, will form the shorter arm of the L-design about 230 ft. long facing the roadway, as also the first 145 ft. of the longer arm which extends to a total length of nearly 325 ft. The remaining 180 ft. length of the longer arm is occupied by the technological block, which has a covered floor area of about 16,000 sq. ft. The main entrance will be on the outside of the corner of the L, facing the roadway.

On the ground floor of the main building, three spacious museum rooms will form the major part of the frontage. By the side of these will be a drawing office and blue-print room; while facing them across a central corridor which runs the whole length of the L will be the physical and physico-chemical laboratories, in which spectroscopic, spectrophotometric, X-ray and other equipment for the study of physical properties will be housed. Other rooms on the same floor will include a room for optical testing and instruments, electrical laboratories, laboratory for enamelling and decorative work, a constant-temperature room and a dark room for photographic and spectrographic work. On the first floor, directly above the museum rooms, will be the conference room, library and the lecture hall; there will be sitting-rooms for officers above the main entrance. Facing the library and lecture hall across the corridor will be the chemical laboratories, and in the other wing on this floor there will be a room for petrographic and microscopic work, and also three rooms for office, records and statistics.

The construction of the technological block was started in September 1945 and is now nearing completion. The installation of services is in progress. This block contains a maintenance workshop, a clay-working laboratory, refractories laboratory in which units for spalling tests, underload tests and P.C.E. values of refractory material will be accommodated; a room for treatment of raw materials such as crushing, grinding, grading, etc., and a large furnace room in which a number of experimental furnace units are to be housed.

In choosing the L-shaped design, particular consideration has been given to the possibility of future expansion, and both the main building and the technological block are capable of considerable expansion independently without detracting from the architectural harmony of the entire structure. Besides, due attention has been given to adequate lighting and ventilation, ease of movement and communication inside the building, as well as suitability to local weather conditions. It is proposed that the main building shall be air-conditioned.

In view of the developments in fittings and devices used in laboratory services and of the great importance of such services in a laboratory, much attention is being given to this feature. Besides an adequate water supply, the Institute laboratories will have town gas supply, A.C. and D.C. electric supply and service lines for compressed air and vacuum according to requirements.

Functions

The functions of institutions concerned with technological subjects are objective in character, namely, the improvement and development of the particular industry or industries with which they are connected. This forms the chief objective of the Institute, and in keeping with it greater emphasis will be laid on industrial research and development of glass and ceramic processes. However, it is to be borne in mind that fundamental research has also to be promoted and encouraged, as without advancement in fundamental knowledge, no new industrial work of importance will be possible. Thus the Institute will aim at fundamental research having a bearing on different branches of glass and ceramics.

To attain its objective of helping the growth and development of the glass and ceramic industries, the Institute must engage in activities of a diverse character. In a country like India, where the number of technically trained persons engaged in industries is very small, and knowledge about many of the methods of manufacture followed nowadays abroad is either completely lacking or scanty, an institution which can give technical assistance to the industry can serve a very useful purpose. To give such technical assistance will, therefore, be one of the immediate functions of the Institute. This will be directed largely towards improvement of the existing technique of manufacture followed in Indian factories, as well as helping in the adoption of manufacturing processes which have so far not been undertaken in India. Such technical assistance is expected to be largely confined to the early stages, until the progress of these industries encourages the growth of independent consulting technologists and agencies; and as these grow, the Institute will curtail this aspect of its activities. To promote the above aim, the Institute will also undertake the collection of data and dissemination of information by means of publications, discussions, lectures and visits of technical personnel to industrial works.

Training of technologists is another important function which the Institute will perform; but as there are other institutions in the country which have courses for training students in glass and ceramic technology, it is not intended to duplicate their work. The training given under the auspices of the Institute will therefore be confined to a few students who will be provided with facilities to acquire practical experience in the application of scientific methods to the solution of industrial problems, so that they may be able to take independent charge of technological duties in glass and ceramic factories.

Another function of the Institute will be to serve as a central organisation for the testing, grading and standardization of glass and ceramic raw materials and finished articles. This will include calibration of appliances and control instruments. As yet, there is no organisation in the country to carry out work of this nature. The Indian glass and ceramic industries have no specifications for raw materials or finished goods; and it is difficult to expect that specifications followed abroad can be strictly applied to present-day Indian conditions. It is felt that certain standards suitable to Indian conditions should be laid down, and the Institute will help in formulating them and revising them from time to time as the industry progresses.

In the majority of investigations undertaken at the Institute, it is expected that laboratory-scale experiments will suffice; but as the translation of laboratory results into commercial operations often involves aspects not covered by laboratory work, the Institute will carry out investigations on a pilot-plant scale. In this work it is expected that assistance from industrial concerns situated in Calcutta will be readily available.

To fulfil its purpose, it is scarcely necessary to stress the importance of the Institute maintaining the closest relations with the industries in India. Also, being a central organisation engaged in glass and ceramic technological work, it will keep in contact with similar organisations abroad.

Staff

The wide and exacting functions of the Institute demand that the directing staff, apart from possessing high scientific abilities, should be able to inspire a spirit of team-work and create an enthusiasm for it, and the Council is fully alive to these requirements. Although ultimately the Institute will have separate sections for glass, porcelain, enamels and refractories, during the period of organisation it will function largely on a composite basis; and it is rather early to say, at this stage, what will be the full complement of technical or other staff; but it is hoped that in the final stages the senior technical staff of the Institute will consist of a director in charge of the Institute with two assistant directors and three research officers specialized in different branches. To assist them there will be five junior research officers and a number of research assistants and research students. In the appointment of the staff, care will be taken to ensure that all branches of glass and ceramic technology are well represented, so that investigations on all aspects can be successfully conducted by those qualified for the work.

The foundation stone of the Central Glass and Ceramic Research Institute was laid by the Hon. Sir Ardeshir Dalal, Member for Planning and Development, Viceroy's Executive Council, on December 24, 1945.

SECRETION OF RED BLOOD CORPUSCLES

By Dr. FREDERIC DURAN-JORDA
Director of the Pathology Department, Ancoats Hospital, Manchester 4

STUDYING the problem of hæmopoiesis, we arrived at the conclusion that the red blood corpuscle was a product of secretion by a monoglandular cell, which, when present in the peripheral blood, has been classified as a polymorph eosinophil[1]. At that time, however, we were unable to demonstrate fully how this red blood corpuscle secretion could be seen objectively by research workers.

Since then, however, we have been able to see this red blood corpuscle secretion clearly in the hæmorrhagic cysts present in some thyroid glands, and also to appreciate its significance by using similar methods to those we have previously described in the study of fat secretion in milk and pus formation[2].

The process of hæmopoiesis in mammals takes place in two stages, which can both be studied objectively.

The first stage is the formation of the granules in the cytoplasm of the cell, which will become preformed red blood corpuscles. This phenomenon takes place in man in the stomach and intestines, and can be examined easily in the abomasum of the Herbivora, cattle and sheep[3].

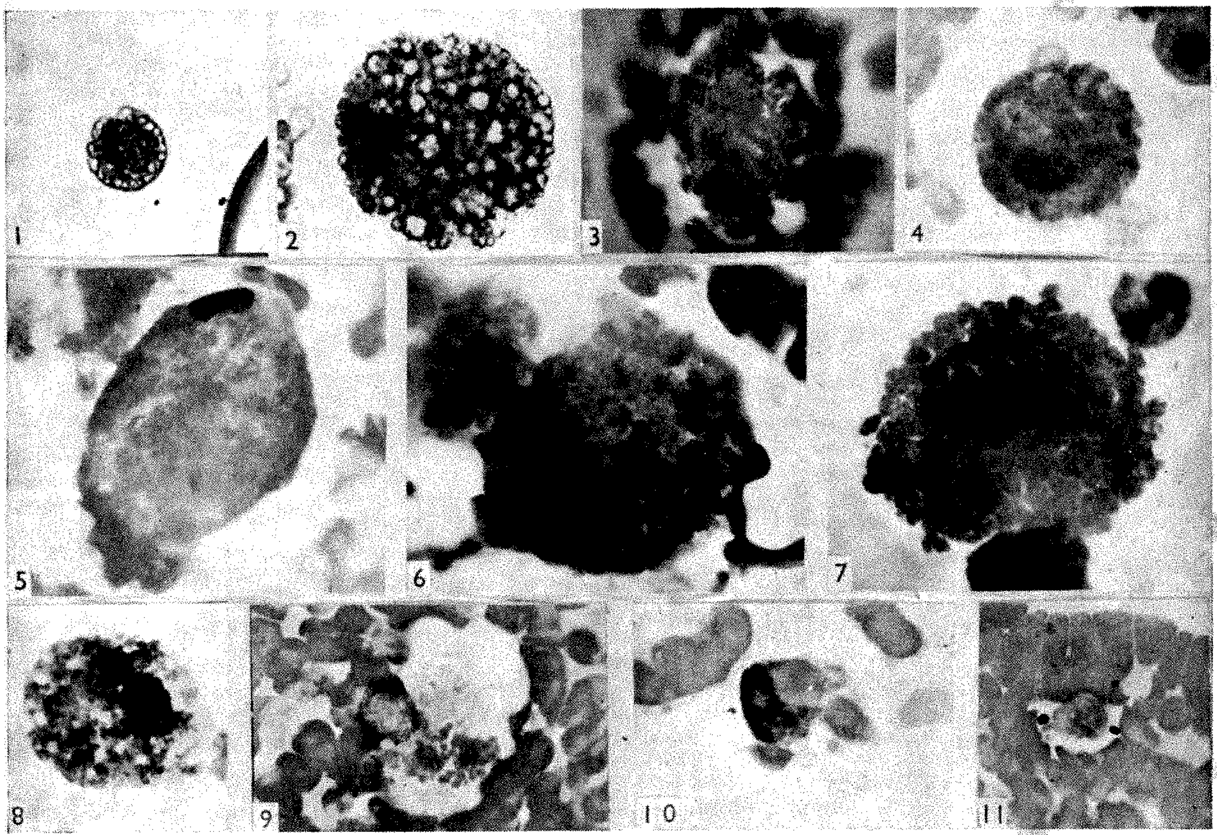
The second stage, the secretory one, is the stage by which the cell, from the aspect of a polymorph eosinophil, develops into a cell of a very large size, which eventually, after expelling the red blood corpuscles, shrinks and becomes a lymphocyte.

The hæmorrhagic cysts present in some thyroid glands were punctured immediately after thyroidectomy, using a capillary pipette which filled spontaneously with hæmorrhagic fluid. Part of this fluid was mixed with saline solution containing 1 per cent of 3·8 per cent sodium citrate solution, and added to the mixture were a few drops of methylene blue. The remainder of the contents of the capillary pipette were made into dry smears, which were stained with May–Grunwald Giemsa. In the wet films, we found that we could divide the cellular contents into three groups, as we had observed in the study of milk and pus.

(1) The first group was formed by what appeared to be polymorphonuclears which had a cytoplasm full of lipoid droplets with the same appearance as eosinophils in wet films (Fig. 1).

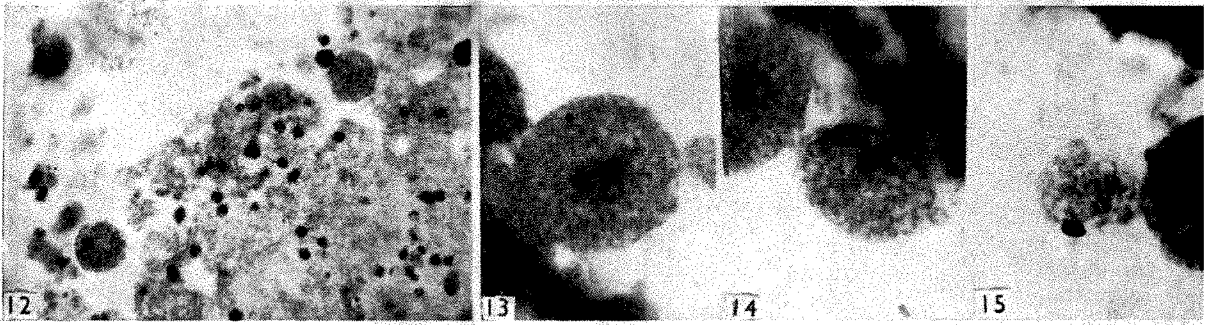
(2) The second group consisted of mononuclears which attained a tremendous size of more than 40 μ in diameter, and contained lipoid droplets in their cytoplasm, which were more homogeneous in size than those found in our previous studies of milk and pus cells, and reached a maximum size corresponding to a red blood corpuscle (Fig. 2).

(3) The third group consisted of smaller mononuclears which contained a fewer number of droplets



Smears stained with May–Grunwald Giemsa

1 and 2, Wet films of thyroid fluid, showing one cell with the aspect of a polymorph eosinophil, and another cell in full development; 3, polymorph eosinophil containing very large granules; 4, a mononuclear containing granules of eosin-like small red blood corpuscles; 5, a mononuclear with a nucleus compressed against the edge of the cell; 6 and 7, large cells filled with about 200 red blood corpuscles; 8 a cell in the process of shrinking and expelling red blood corpuscles; 9, a cell after shrinking which still contains granules of eosin; 10, lymphocyte showing a double feature—a lymphocytic nucleus and a fully developed red blood corpuscle (notice that the lymphocyte still contains some granules of eosin); 11 lymphocyte with one granule of eosin.



SECTIONS STAINED WITH HÆMATOXYLIN AND EOSIN

12, Section from intra-acinar hæmorrhage in a thyroid (notice cells of different sizes containing red blood corpuscles); 13 and 14, high magnification of two cells full of red blood corpuscles; 15, a cell in the process of expelling red blood corpuscles and shrinking.

and occasionally red blood corpuscles. Some of the cells were like a lymphocyte with a cytoplasm still containing a few lipoid granules.

Studying the dry, stained films, the evolution of the cells could be easily observed, as in this case the material which the cell contained was not dissolved by the alcohol used in the stain, and we could, therefore, follow the evolution of the cells easily in all the intermediary stages.

Again, our findings could be classified into three groups of cells.

(1) The group formed by different sizes of polymorph eosinophils which contained granules varying from normal eosinophil granules to very tiny red blood corpuscles (Fig. 3).

(2) In the second group, there was a range of mononuclears growing to a gigantic size, and, taking into consideration the normal size of one red blood corpuscle and the diameter of the large cells, which was approximately 40 μ, we could estimate roughly that the largest cells must contain about two hundred red blood corpuscles. All the space in the cytoplasm of the cell was occupied by red blood corpuscles, and in some cases it could be seen how the nucleus was pressed against the periphery of the cell (Figs. 4–8).

(3) This group consisted of small mononuclears, some of them having the typical appearance of a lymphocyte; in which case it could be seen that the lymphocyte still contained eosinophil granules in the cytoplasm, or occasionally a cell showed a double feature, namely, a lymphocytic nucleus together with a red blood corpuscle, all surrounded by a small halo of cytoplasm (Figs. 9–11).

These previous observations can be confirmed by studying some sections of thyroid which show intra-acinar hæmorrhage, in which case it is also possible to study these three different ranges of cells as found in the fluid from hæmorrhagic cysts (Figs. 12–15).

Studying the cells by micro-incineration, we could demonstrate that the lipoid droplets contained in the cytoplasm of the cells leave similar ash to the ash deposited by the red blood corpuscles.

If we accept that the red blood corpuscle is a product of secretion, the basis of hæmatology as it is at present understood will be changed, and there are some facts concerning this which should be discussed.

Biologists are able to study in different tissues cells which contain in their cytoplasm a small quantity of red blood corpuscles, and they have interpreted this as a phenomenon of phagocytosis; but if a cell contains about two hundred red blood corpuscles, which completely fill its cytoplasm, there is no room left for their digestion.

It is very surprising to find that our observations of red blood corpuscle formation and secretion by a monoglandular cell are similar to the observations made by Kolliker in 1854[4]; Kolliker describes how cells which contained in their cytoplasm a large quantity of red blood corpuscles shrunk until they became a small granulated cell (? eosinophil). Kolliker, therefore, saw the same thing we have described, but did not interpret it in the same way.

If the life of the red blood corpuscle is a hundred days, the daily development of approximately 250 polymorph eosinophils per cub. mm. will be enough to make good the wear and tear of the red blood corpuscles. This is more understandable than the actually accepted theory that the 5,000 normoblasts per cub. mm. present in a normal bone marrow, which is one third of the volume of the whole blood, should produce daily 150,000 red blood corpuscles, a rate of thirty mitotic divisions per cell in twenty-four hours. This fact in itself is quite extraordinary; but it becomes even more so when it is supported by a process of maturation and denucleation, this latter being so mysterious that it is still under discussion as to whether it takes place by a mechanism of nuclear expulsion or by one of karyorrhexis of the nucleus.

I should like to thank Prof. Wood Jones for his interesting and helpful discussions concerning this work. Also the surgeons of Ancoats Hospital for their kind co-operation with surgical specimens, and Mr. J. B. Dean for his assistance with the photomicrographs.

Conclusions

It is suggested that to study objectively the process of red blood corpuscle secretion in man, the hæmatic fluid from hæmorrhagic cysts present in some thyroids should be used, and the following conclusions have been arrived at.

(1) That the polymorph eosinophil is the carrier of pre-formed red blood corpuscles.

(2) That the polymorph eosinophil, by increasing its size and developing its granules, reaches the stage of a cell which has a cytoplasm containing about two hundred red blood corpuscles.

(3) The cell, after expelling the red blood corpuscles, shrinks and becomes a lymphocyte.

(4) This cycle of monoglandular red blood corpuscle secretion follows the same biological steps as the similar monoglandular processes which take place in the secretion of fat milk, and pus formation.

SCRUB TYPHUS AS A STUDY IN ECOLOGY*

By Lieut.-Colonel J. R. AUDY, R.A.M.C.

Scrub Typhus Research Laboratory, S.E.A.C., and London School of Hygiene and Tropical Medicine

MITE-BORNE scrub typhus (tsutsugamushi disease) was a serious military problem in the Japanese campaign, and units unlucky enough to strike endemic foci suffered heavily[1]. The epidemiology of the disease was investigated in North Burma by the U.S. Typhus Commission, and in the Imphal area (Manipur, Assam) by a team based on the Scrub Typhus Research Laboratory, which attempted to do complementary work, particularly on the ecology of the disease.

The general findings of this team are shortly to be published, but this present note concerns an interesting aspect of its investigations, namely, the way in which light may be thrown on the ecology and behaviour of small mammals by a study of their infestation by Trombiculid mites.

This is possible because the Trombiculid mites are partly soil-bound: the non-parasitic nymphal and adult stages spend their lives in the soil, while the larvæ alone parasitize warm-blooded animals. The larvæ feed but once before returning to the soil for metamorphosis, the feed lasting from four days to several weeks according to the species. These mites have actually to be introduced to suitable foci, and will continue to infest such foci only if hosts pick up larvæ and return a proportion to the same place, thus maintaining a mite–mammal–mite cycle related to a patch of ground which may be far from the actual nest of the mammal. These mites are not conspicuous within or around rat-burrows, but appear to be liberated and picked up around feeding-places. There is a close parallel between these mites and the jigger flea *Tunga penetrans*, the larvæ of which are soil-bound while the female adults attack man.

Even though the larvæ can move quickly when stimulated, the range of movement of both larvæ and adults appears to be greatly limited, so that a heavily infested spot may adjoin an almost mite-free area a yard or two away. It is clear that such a parasite can serve as an ecological label, especially if its distribution is restricted or if the non-parasitic phase makes ecological demands of its own on the soil, which appears to be the case to a varying degree with different species.

The species most closely studied was *Trombicula deliensis* Walch, the vector of scrub typhus, while, for numerical as well as other reasons, the most important host for this and most other Trombiculids was *Rattus rattus* in its local varieties. An investigation of the distribution, population, and rate of turnover (namely, the number of larvæ becoming attached to rats daily, related to the short time, 3–5 days, spent on the host) indicates with little doubt that this species is the most successful Trombiculid ectoparasite of rats in the whole of the Far East. It is very closely related to *T. akamushi*, which shares part of its distribution in Malaya, New Guinea and the Philippines, and is the classical vector of tsutsugamushi in Japan.

That Trombiculid mites occur in 'islands' related to a restricted range of the principal host was illustrated several times, but particularly while trapping in a series of plots 50 yd. × 50 yd. in a strip transecting a large expanse of scrub near Imphal during December–January 1946, when 109 rats were caught. For the first 400 yards, 32/50 of the infested rats (*Rattus rattus* var.) caught carried apparently pure cultures of *Ascoschöngastia mutabilis* Gater, 1932, while a few were infested by this species mixed with a congeneric but distinct species, *A. kohlsi* Philip and Woodward, 1946, and only one rat with *A. kohlsi* alone. For the next 200 yards, 27/36 (75 per cent) were infested by a mixture of both species, while for the last 150 yards to the end of the transect, 20/23 (87 per cent) were infested by pure cultures of *A. kohlsi*, and not one by *A. mutabilis* alone. The existence of two such 'islands' of infestation by these two species, overlapping for less than 200 yards, is in this particular instance explicable by the restricted range of the rats in the rank scrub. The two species concerned remain attached to rats for a week or more: they are picked up and, after that time, dropped on to the ground near by. This restriction of range was illustrated in this same area by the trapping on two occasions of a grey rat (at present unnamed) which could be distinguished from the common species: in one of the plots, six of the eight rats caught were grey, and were all trapped within a circle of 30 yd. diameter, while near by three rats of the same grey species were caught one day in three adjacent traps.

It will be understood that these two overlapping 'islands' of infestation are not a picture of a permanent state, but of a stage in a dynamic situation. The rate at which the zone of overlap expands in both directions depends particularly upon the range of movement of the rats.

There are many examples of differential infestation of rats in contiguous areas. Gater[2] noted that two common Malayan mites, *T. munda* and *Gahrliepia fletcheri*, appear to be more common in villages than elsewhere. We found an undescribed species of *Schöngastiella* to have a similar distribution. Rats (239 *R. rattus* var. in October–November 1945) were trapped in Mongjam village near Imphal, and 87 per cent were infested by this species, while of these 44 per cent were 'pure cultures', showing that nearly half the rats were exposed to fairly uncontaminated 'islands' of infestation by this species. The infestation of these village rats by *T. deliensis* was 40 per cent, only 17 per cent of these being pure cultures. This contrasted with the findings in rats of the same species trapped in hill-foot scrub a few hundred yards away across a belt of rice-fields, where only 30 per cent were infested by *Schöngastiella* (26 per cent pure cultures), and 90 per cent by *T. deliensis* (64 per cent pure cultures). It is likely that the considerable evacuation of the village by the natives, which coincided with the establishment of military camps in the hill-foot area in 1942–43, led to a migration of a number of rats from the village to the camps, and to the seeding out of many colonies of *Schöngastiella*. This species remains attached to its host for a month or more.

The influence on the mites of the high rat population which frequented the scrub immediately on the edge of a camp was investigated by laying down lines of rats in small cages and counting and identifying the mites which they picked up in twenty-four hours. It was found that there was a rapid and significant increase in mite population as the immediate perimeter of the camp was approached.

---

* Published by permission of the Army Medical Directorate, War Office.

A similar investigation transecting the junction between grassy scrub and a strip of forest following a water-course showed a significant and high population of mites in the narrow intermediate belt of dense vegetation between open scrub and forest. Such ecotones have repeatedly been associated with scrub typhus: we have been calling them 'fringe-habitats', and including hedgerows as a special case within this category.

The seasonal changes in vegetation were found to be considerable, to be related to seasonal variations in behaviour and population of the rats, and to be very intricate. Even so, some useful light was thrown on this complex picture by a study of the infestation of the rats, although the following discussion is intended to suggest ways in which this can be done and not to present a picture of what was actually happening in the Imphal area, where our investigations were very greatly limited and, in ignorance, not properly designed to this end.

T. deliensis, like *T. akamushi*, is a seasonal mite, in that the larvæ become very scanty during the dry season, whereas they appear in great numbers shortly after the onset of the rains. The 1945–46 inter-monsoon period in Imphal was unusually dry; but even so, at its height larvæ of *T. deliensis* could always be recovered from foci on seepages or by perennial streams which were kept moist by ground water, while they had almost completely disappeared from exposed dry sites. At such a time, it is possible to use this species in selected areas as an index of the host behaviour in relation to water-points, as well as an indicator of the behaviour of the hosts during the different seasons. This, however, needs very extensive collections: only one application appears to be worth while with the Imphal material, and that is to group the rats according to intensity of infestation (0, 0–10, 10–50, 50–100, 100–200, and more than 200 mites per rat), and to study the frequency of distribution of the rats within these groups month by month, in conjunction with the rate and average intensity of infestation. As this can be done only with pure cultures of the species, *T. deliensis*, being investigated, it is clear that we are dealing with a selected sample of rats exposed on fairly uncontaminated '*deliensis* islands'. This study shows that with the first flood of larvæ which appeared after the rains broke in May 1945 there was a very high rate of infestation (more than 70 per cent) but a relatively low intensity, most of the rats being in the 10–50 mites-per-rat group. Two or three months later, there was a distinct shift in distribution from the low-intensity groups to the highest. At the height of the following dry season, the rate of infestation fell from more than 60 per cent to less than 10 per cent, and particularly the lowest and the highest intensity groups were represented. This *suggests* either an initially dispersed appearance of larval mites, or a wide and variable range of movement of the rats, or more probably both, followed later probably by a second generation of larvæ in more compact conditions of association between mite and rat. Later still, the larvæ were scarce and a few rats remained heavily infested because they were in moist foci where the larval population was being maintained.

All these findings have a bearing on the ecology of scrub typhus itself. The disease is very sharply localized, and has an ecology of its own, which is related to vegetation and terrain but not directly to any specific plant, although most of the typhus appears to reside in rank grassy undergrowth, on waste-land or water-meadows, or in the fringe-habitats at the edge of such tracts.

It is considered that a planned study of the Trombiculids infesting rodents and shrews, as well as the other ectoparasites such as fleas and gamasid mites which appear to be related to the *domestic* habits of the hosts, is an economical method of investigation, because it throws as much light on the mammals as it does on a variety of ectoparasites. It is a synecological approach.

OBITUARY

Prof. A. A. Glagoleva-Arkadieva

A YEAR has passed since the death on October 30, 1945, of Alexandra Andreevna Glagoleva-Arkadieva, professor of physics at the University of Moscow. Prof. Glagoleva-Arkadieva was born in 1884. Upon leaving a secondary school in Tula, she worked as a country school-teacher during 1900–6. In 1910 she completed the Moscow Higher Courses for Women, where she studied physico-mathematics, attending lectures by Prof. A. A. Eichenwald and N. A. Umov, the physicists. Following her graduation she became an assistant in physics at the courses, which after the Revolution of 1917 were reorganised into the Second University of Moscow.

During the First World War, Glagoleva-Arkadieva organised an X-ray room at the war hospital belonging to the Higher Courses, where she designed and built an instrument called the roentgenostereometer for determining precisely the location of bullets or shell splinters in the human body. The fundamental theory of this instrument, which enabled an observer to make precise measurements of depth at any ocular distance, was worked out by the designer herself. After the War the instrument found application in midwifery. With her wealth of practical experience, Glagoleva-Arkadieva for a number of years gave a highly popular lecture course in X-rays for medical men and students.

In 1920, Glagoleva-Arkadieva initiated research in the J. C. Maxwell Laboratory at the University of Moscow on the generation of millimetre electric waves, which was necessary for the study of magnetic properties in the frequency range in which an abrupt drop in permeability of iron and nickel approaching unity had been detected in 1912. Already in 1922 she was able to report to the convention of Russian physicists on a mass radiator, on a new source of ultra-short electric waves. This source, which she described in 1924 in a communication in *Nature* (May 3, 1924, p. 640), made it possible to obtain wave-lengths from several centimetres to 82 microns. Her method consisted in passing electric sparks through a mixture of filings and viscous oil (vibrational mass). The new rays she obtained more than filled the gap between radio-waves and the long infra-red waves of Rubens that had remained in the wave scale since the time of O. Lodge and P. Lebedev. The ease of obtaining interference curves of the waves of the mass radiator pointed to the formation of undamped very short waves during spark discharges; this was corroborated by Leontieva in 1925, and more recently by H. G. Kelliher and E. T. S. Walton.

The distribution of the radiating power on the surface of the vibrational mass of the mass radiator—

the spectral composition of the radiation at its various points—was investigated by Glagoleva-Arkadieva in 1928. Simultaneously, with the aid of her wave detector thermo-element, she investigated the long-wave radiation of the mercury lamp. Since she employed a Boltzmann interferometer, she obtained a symmetrical interference curve, which was 2·5 times longer than that obtained by previous investigators; the curve gave a wave-length of 340 microns.

During 1932–33, A. A. Glagoleva-Arkadieva, employing an echelette grating, isolated from the mixed radiation of the mass radiator pure waves ranging from 9·9 mm. to 350 microns in length. In 1937 she developed a method of reticulate filters making it possible to isolate bands of definite width. The method is based on the utilization of Hertz gratings folded crosswise. The last ten years of her life found her studying the mechanism of the mass radiator and developing its theory of operation. She established that filings of irregular shape are more effective than spherical ones, and that the smallest particles still giving vibrations had a length of 0·02 mm. She showed that in the radiation of the mass radiator there are three principal waves: one conditioned by vibrations in individual grains (as in the sphere of the Lodge vibrator); another by the vibrations of a pair of grains (as in the Lebedev vibrator); while the third wave depends upon the design of the apparatus and arises from the vibrations in the chains of particles that form in the vibrational mass when sparks jump across. Her mass radiator has been applied to measurements in the field of millimetre waves, which other generators of electric vibrations do not produce.

A. A. Glagoleva-Arkadieva was able to combine her outstanding research with extensive teaching and other activity. Only in 1937, on medical advice, did she resign her position as head of a department at the Second Moscow Medical Institute, and in 1939, at the University of Moscow. She trained many teachers, medical radiographers and research workers, who have high praise for her power to imbue a love for science. By decision of the Academy of Sciences of the U.S.S.R. a collection of the papers of A. A. Glagoleva-Arkadieva is to be published.

A. IOFFÉ

NEWS and VIEWS

Alexander Graham Bell (1847–1922)

THE name of Alexander Graham Bell, who was born in Edinburgh on March 3, 1847, will always be associated with two memorable achievements: the invention of the telephone and the education of the deaf. His interest in the human voice was inspired by his father and grandfather, both authorities in phonetics and elocution. From his mother he inherited a remarkable appreciation of tone values. In 1868 he began to teach his father's system of 'visible speech' for the deaf at a school in Kensington. Two years later he accompanied his parents to Canada, and in 1873 he was appointed professor of vocal physiology at Boston University. It was his simultaneous study of the air waves in the ear during the utterance of voice sounds, and of a tuned system of multiple telegraphy, which led to the invention of the telephone. In June 1875 he made his first telephone at Boston, and on March 10, 1876, sent the first intelligible message: "Mr. Watson, come here; I want you". His novel machine was demonstrated before the American Academy of Arts and Sciences in Boston two months later, and was introduced to the world at the Philadelphia Centennial Exhibition. The Bell Telephone Company was inaugurated in the following year. With the Volta Prize of 50,000 francs awarded by the French Government in 1880, Bell financed the Volta Bureau in Washington for the increase and diffusion of knowledge relating to the deaf. Interested in the subject of marriage of the deaf, he took up the study of eugenics, while after 1895 aviation chiefly engaged his attention.

This issue of *Nature* (dated March 1) and also that dated February 22 were not printed until after the restrictions on the use of electric power were removed on March 3

National Research Council, Canada: Appointment of Dr. David A. Keys

DR. DAVID A. KEYS, Macdonald professor of physics at McGill University, has been appointed vice-president of the National Research Council, Canada, in charge of the atomic energy establishment at Chalk River, Ontario. The National Research Council has now taken complete responsibility for the operation of this undertaking. Hitherto, the National Research Council was responsible for the Research Division on Atomic Energy, of which Dr. W. B. Lewis is director, but Defence Industries Ltd. was in charge of the construction and operation of the industrial, pilot plant facilities and the village of Deep River. Dr. Keys has had a long and impressive experience in research, scientific education and administration. Born in Toronto, he attended Upper Canada College and had a brilliant record at the Universities of Toronto and Cambridge and Harvard University. He joined the staff of McGill University in 1922.

National Research Council for Natural Sciences in Sweden

IN addition to the already existing National Research Councils for Technology, for Medicine and for Agriculture, a new Research Council for Natural Sciences has recently been established in Sweden by a royal charter. The new Council will have as its most important task the distribution of funds for fundamental research in the natural sciences and mathematics and the granting of fellowships for scientific studies and expeditions abroad. The Council will also encourage and support work for the international relations of Swedish research workers and institutions. The Swedish Parliament has granted one million Swedish crowns to the Council for the present fiscal year. The president (Prof. Arne Tiselius, Uppsala) and two other members (Prof. T. Caspersson and Prof. Bo Kalling, Stockholm) are appointed by the King. The other four members of the Council are Prof. B. Lindblad, elected by the Royal Academy of Sciences, Prof. E. Melin, elected by the University of Uppsala, Prof. B. Edlén, elected by the University of Lund, and Prof. K. Myrbäck, elected by the University of Stockholm. The secretary is Dr. G. Funke, and the address is Statens Naturvetenskapliga Forskningsråd, Besmansvägen 10, Åkeslund (Stockholm). One of the first actions of the Council has been to extend an invitation to Prof. D. R. Hartree, of the Cavendish Laboratory, Cambridge, to visit Sweden and to lecture on modern calculating machines.

British Society for the History of Science

On November 22, 1946, a meeting of persons interested in the history of science was held at the Science Museum, South Kensington. The purpose of the meeting was primarily to consider how Great Britain could best associate itself with the International Academy for the History of Science, which is about to seek affiliation with the International Council of Scientific Unions. After some discussion, it was unanimously decided that a History of Science Society should be formed, which could act as a national group and so fulfil one of the conditions necessary for association with the International Council. A committee was thereupon appointed to draw up a draft constitution for such a society. This Committee reported its recommendations to a further meeting of the original body on February 12, and as a result a provisional constitution was adopted, of which the following are the chief points.

The society is to be known as the British Society for the History of Science, and its objects are to further the study of the history of science (*a*) by meetings for the reading and discussion of papers; (*b*) by facilitating the publication of relevant material; (*c*) by co-operation with other interested bodies; and (*d*) by any other means that the Council of the Society may consider desirable. Membership is to be open to all interested in the subject who satisfy certain formal conditions, on payment of a subscription which for the first year is to be one guinea. The committee which drafted the constitution is to remain in office until the first annual general meeting, which is to be held in May next, when officers and council are to be elected. The provisional honorary secretary is Mr. F. H. C. Butler, "Ravensmead", Keston, Kent. He will be glad to hear from any who wish to become members. Steps for making the existence of the Society known are under consideration, and a statement will be issued in due course.

A Biological News-Letter

Biologists will be interested in the new Monthly News Letter *Biologia* which Dr. Frans Verdoorn is publishing as a supplement to *Chronica Botanica*. The intention is that this News Letter should be kept small and informal, as previous experience has shown that more extensive news magazines tend not to be read and well used by those for whom they have been prepared. It is the intention in *Biologia* to print information relating to methodological and professional aspects of biology rather than to publish special articles or subjects for discussion. In the first issue, that for January 1947, biologists will find much contemporary information which they might otherwise, in a busy life, tend to overlook. It contains, for example, brief references to a wide range of current biological activities such as UNESCO's first general conference, notices of various scientific congresses and meetings, new editions of such books as "The International Rules of Botanical Nomenclature", the International Zoological Station at Naples, a list of research scholarships, fellowships and grants supported by industry in the United States, scientific institutions in the Ukraine, and so on. The biological world thus owes a further debt of gratitude to Dr. Verdoorn for his many activities in their interest.

A New Heat-absorbing and Heat-resisting Glass

The German name for the focus of a lens, *Brennpunkt*, records an observation that is only too well known to both professional and amateur cinema operators. All our ordinary sources of white light radiate a large amount of energy at 'infra-red' frequencies, and a material such as a film placed in the image of a strong source may readily absorb this energy even if it transmits most of the visible light, and be likely to burn unless the exposure is very short. Various efforts have been made to avoid this trouble by producing a filter which will remove the infra-red while transmitting the visible. Water-cells are sometimes employed, but they are inconvenient and not very efficient. The late Sir William Crookes experimented with various glasses. One which he produced had a good infra-red absorption, but had a strong green colour in any thickness more than about 2 mm.; it was said to contain iron in the ferrous condition. One of the troubles with glasses of this kind is that they are subject to marked heating; and unless the filter is uniformly illuminated and heated there must be unequal expansion. Unless the material has a low thermal expansion it may crack.

Messrs. Chance Bros., Ltd., have recently produced a new heat-absorbing glass, *ON* 19, which represents a considerable advance on one previously listed in their catalogue. If the source is an ordinary gas-filled lamp of the projection type, it is claimed that, at a thickness of 6·0 mm., a sheet of this glass will transmit 81 per cent of the visible light, but only 4·5 per cent of the heat; it is said to be virtually colourless, and of good durability, moreover, having good heat-resisting properties. For use in projection systems, it is suggested that it should normally be placed near the condensers, on the side of the lamp; some form of forced cooling is usually necessary. The filter can sometimes be cut into strips further to reduce the risk of fracture. The glass is stocked in rolled sheets, 5–6 mm. in thickness. It is likely to contain scattered fine bubbles and is not intended for optical use other than as a filter. It should find many useful technical and scientific applications.

Royal Astronomical Society: Officers

The following have been elected officers of the Royal Astronomical Society: *President*, Prof. W. M. H. Greaves, Astronomer Royal for Scotland and professor of astronomy in the University of Edinburgh; *Vice-Presidents*, Miss M. G. Adam, chief assistant (astronomy), University Observatory, Oxford; Dr. M. Davidson; Prof. H. H. Plaskett, Savilian professor of astronomy, University of Oxford; D. H. Sadler, superintendent of the Nautical Almanac; *Treasurer*, Sir Harold Spencer Jones, Astronomer Royal; *Secretaries*, Prof. W. H. McCrea, professor of mathematics, University of London (Royal Holloway College); Dr. A. D. Thackeray, assistant director, Solar Physics Observatory, Cambridge; *Foreign Secretary*, Prof. F. J. M.

Stratton, professor of astrophysics and director of the Observatories, University of Cambridge; *Council*, Dr. R. d'E. Atkinson, chief assistant, Royal Observatory, Greenwich; B. C. Browne, lecturer in geodesy, University of Cambridge; Dr. H. A. Brück, John Couch Adams astronomer, and assistant director of the Cambridge Observatory; D. L. Edwards, director of the Norman Lockyer Observatory, Sidmouth; Dr. M. A. Ellison; C. C. L. Gregory, director and Wilson observer, University of London Observatory; F. Hoyle, lecturer in mathematics, University of Cambridge; Dr. A. Hunter, assistant, Royal Observatory, Greenwich; Dr. E. H. Linfoot, lecturer in mathematics, University of Bristol; P. J. Melotte, assistant, Royal Observatory, Greenwich; Prof. E. A. Milne, Rouse Ball professor of mathematics, University of Oxford; Dr. W. H. Steavenson, Gresham professor in astronomy.

Institution of Electrical Engineers Scholarships

The Council of the Institution of Electrical Engineers is offering the following scholarships: *Research Scholarships:* Ferranti Scholarship (£250 a year for two years); Oliver Lodge Scholarship (£250 for one year); Swan Memorial Scholarship (£150 for one year); C. P. Sparks War Thanksgiving Fund (a grant not exceeding £100 for one year). *Student Scholarships:* Duddell Scholarship (£150 a year for three years); Manville Scholarship (£150 a year for three years); Silvanus Thompson Scholarship (£100 a year plus fees for two years); Salomons Scholarship (£100 for one year); David Hughes Scholarship (£100 for one year); Paul Scholarship (£50 a year for two years); Thorrowgood Scholarship (£25 a year for two years). Particulars and nomination forms, to be returned by April 15 (student scholarships) or June 1 (research scholarships), can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

University of Leeds: Appointments

The following appointments have been made in the University of Leeds: Dr. A. J. Brown, lately fellow of All Souls College, Oxford, to be professor of economics and head of the Department of Economics and Commerce; Dr. A. L. Roberts, senior lecturer in refractory materials, to be Livesey professor of coal, gas and fuel industries; Dr. G. S. Rushbrooke, Brotherton research lecturer in physical chemistry, to be lecturer in mathematical chemistry.

The Night Sky in March

Full moon occurs on March 7d. 03h. 15m. U.T. and new moon on March 22d. 16h. 34m. The following conjunctions with the moon take place: March 4d. 02h., Saturn 4° S.; March 12d. 15h., Jupiter 0·5° N.; March 19d. 01h., Venus 5° N.; March 20d. 20h., Mercury 7° N.; March 21d. 04h., Mars 4° N.; March 31d. 07h., Saturn 4° S. In addition to these conjunctions with the moon, Mercury is in conjunction with Mars on March 16d. 17h., Mercury being 7° N. Mercury, in inferior conjunction with the sun on March 8, is not favourably placed for observation in the early part of the month. On March 15 the planet rises at 5h. 42m., and on March 31 at 5h. 06m., and can be seen in the eastern sky; but is a difficult object although its stellar magnitude is less than 1 at the end of March, because sunrise takes place only 35 minutes and 45 minutes later on the above dates. Venus is conspicuous as a morning star, rising at 5h. 02m., 4h. 57m., and 4h. 40m., at the beginning, middle and end of the month, respectively. The surface of the illuminated disk varies from 0·643 to 0·736 and the stellar magnitude is about − 3·6 during the month. Mars is not well placed for observation. Jupiter can be seen close to β Scorpii, rising at 0h. 48m., 23h. 54m. and 22h. 49m. at the beginning, middle and end of the month, respectively. The mean stellar magnitude of Jupiter is − 1·8 during March, and the planet is stationary on March 14. Saturn is visible up to the early morning hours, setting at 5h. 37m., 4h. 39m. and 3h. 35m. at the beginning, middle and end of the month respectively. The planet is easily recognized a little west of γ and δ Cancris, its stellar magnitude being 0·2. Occultations of stars brighter than magnitude 6 are as follows: March 3d. 00h. 20·3m., 52 Gemi. (*D*); March 29d. 22h. 46·8m., 37 Gemi. (*D*). The latitude of Greenwich is assumed and *D* refers to disappearance. In addition to these occultations of stars, Uranus (mag. 6) is occulted on March 1d. 01h. 08·1m. Spring equinox occurs on March 21d. 11h.

Announcements

The annual Mather Lecture of the Textile Institute will be delivered by Sir Walter Haworth, professor of chemistry in the University of Birmingham, on the occasion of the annual general meeting of the Institute on April 23; his subject will be "The Chemistry of the Polysaccharides".

Dr. F. W. Haywood, who has been chief metallurgist of Wild-Barfield Electric Furnaces, Ltd., since 1938, has been appointed to the Board of the Company as technical director.

The Challenger Society is prepared to consider applications for small grants in aid of research in marine biology or oceanography at a recognized laboratory during the year April 1947–April 1948. Applications, accompanied by details of the proposed research, should reach the honorary secretary, Mr. Dilwyn John, British Museum (Natural History), London, S.W.7, before April 19.

A Radiocommunication Convention, dealing particularly with war-time activities and their possible influence on peace-time development, has been arranged by the Institution of Electrical Engineers, and will be held at the Institution during March 25–28. Sessions will be devoted to such topics as long-distance point-to-point communication; naval, military and aeronautical communication; pulse communication; short-distance communication; direction finding; and war-time broadcasting. Sir Stanley Angwin will deliver an address on "Telecommunication in War".

Erratum.—In the letter by Dr. G. Whittingham on "The Luminous Decomposition of Nitrous Oxide", in *Nature* of February 15, p. 232: (*a*) 4 lines from foot of the first column, for "due to nitrous oxide" read "due to nitrogen peroxide"; (*b*) last sentence should read "Both these reactions require a high energy of activation[10], and sufficient nitric oxide to give a visible glow with the atomic oxygen present is not produced until high temperatures are attained".

Gyro Interaction of Radio Waves

A THEORY of the interaction of radio waves in the ionosphere, first reported by Tellegen[1] in 1933 and afterwards observed by many others, was given by Bailey and Martyn[2]. According to this theory, the modulation M impressed by the interfering long-wave station on the medium wave-length transmission reflected from the ionosphere in the vicinity of the long-wave station is

$$M = \text{const.} \frac{PD}{\sqrt{1 + \left(\frac{n}{G\nu_0}\right)^2}}, \quad (1)$$

where P is the power, D the depth of modulation and $n/2\pi$ the modulation frequency of the long-wave station. ν_0 is the collision frequency of an electron in thermal equilibrium with the gas molecules in that portion of the E-layer traversed by the wave of medium wave-length. The quantity G is a constant which relates the mean fractional loss of energy of $\overline{\lambda}$ of an electron in collisions with molecules of the gas to the collision frequency ν in a state of motion where the mean energy of agitation of the electrons slightly exceeds that of the gas molecules.

According to Pidduck and Bailey,

$$\overline{\lambda} = G\left(1 - \frac{\nu_0^2}{\nu^2}\right). \quad (2)$$

The laboratory experiments of Townsend and Tizard[3] give $G = 2 \cdot 6 \times 10^{-3}$ for ordinary air, but G may well have a different value in the E-layer.

Expression (1) for the impressed modulation was found by Bailey and Martyn[4] to fit the quantitative observations of van der Pol and van der Mark, with $G\nu_0 = 780$.

According to the first formulation of the theory of Bailey and Martyn, the impressed modulation M, other factors remaining the same, should diminish with the wave-length of the interfering station and should be negligible in practice when the interfering station operates on a medium wave-length. Afterwards, Bailey published[5] a revised theory according to which strong interaction, still described by formula (1), is to be expected when the interfering station operates on or near the gyro-frequency $\omega_0/2\pi = Be/2\pi m$, where B is the total intensity of the earth's magnetic field in the E-layer. Although qualitative observations of this gyro-interaction have been reported[6], it was considered desirable, in view of the practical importance of the phenomenon, both in setting a possible upper limit to the power of a broadcast station operating near the gyro-frequency, and also as a tool for ionospheric research, to carry out some quantitative tests of the theory. The tests, the results of which are given below, were made possible through the courtesy of Mr. H. Bishop, controller of engineering, and of the Engineering Research Department of the British Broadcasting Corporation.

In both tests long-wave transmissions from Droitwich (200 kc./s.) were observed at Dundee after reflexion from the ionosphere to the south (as required by the theory) of the interfering station at Stagshaw (1,050 kc./s.), near Hexham in Northumberland. In the first test, carried out during 0000–0200 B.S.T. July 18, 1946, the existence of the phenomenon of gyro interaction was confirmed and was observed at Dundee using a commercial broadcast receiver, with transmissions from the low-power station at Stagshaw (10 kW. at 1,149 kc./s.)—the gyro-frequency being 1,170 kc./s. Much stronger interaction over the range of audible modulation tones 100–900 c./s. was observed with the higher-power transmitter at Stagshaw (120 kW. at 1,050 kc./s.).

The second series of tests, carried out early in November 1946, was designed to check the validity of formula (1), using the higher-power transmitter at Stagshaw, and Droitwich (200 kc./s.).

Formula (1) may be written,

$$n^2 = \frac{(\text{const.})^2 (G\nu_0)^2 P^2 D^2}{M^2} - (G\nu_0)^2. \quad (3)$$

Thus, if the theory be correct, a linear relation should exist between the square of the angular frequency and the square of the reciprocal of the depth of the impressed modulation.

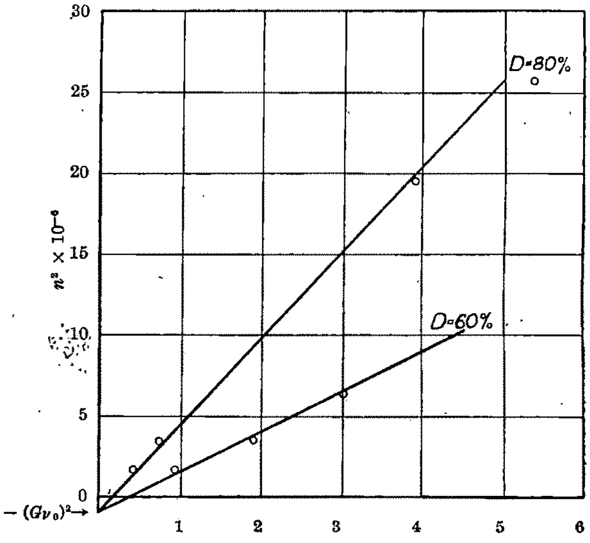

Fig. 1

Fig. 1 shows how the experimental observations accord with expression (3). It can be seen that the points corresponding to a power $P = 120$ kW. and depths of modulation $D = 80$ and 60 per cent lie near straight lines the common intercept of which with the n^2-axis is $-(G\nu_0)^2$. The value of $G\nu_0$ found from the intercept is $G\nu_0 = 950$.

Unfortunately, the accuracy of the measurements at the lower powers P and modulation depths D were poor owing to interference from a distant Russian station operating on the Droitwich wave-length. The points plotted in Fig. 1, however, represent trustworthy measurements.

A further test of the theory was also made. It is implicit in the theory, although not stressed by Bailey, that, accompanying the impressed modulation M given by (1), there is an impressed modulation at the octave frequency $(2n/2\pi)$ the depth of which, M_{oct}, is related to M as follows:

$$R = \frac{M_{\text{oct}}}{M} = \frac{D}{4}\left[\frac{n^2 + (G\nu_0)^2}{4n^2 + (G\nu_0)^2}\right]^{1/2}, \quad (4)$$

whence,
$$\frac{1}{n^2} = \frac{3}{(G\nu_0)^2\left[\left(\frac{D}{4R}\right)^2 - 1\right]} - \frac{1}{(G\nu_0)^2}. \qquad (5)$$

Fig. 2 gives the line representing $1/n^3$ as a function of $1/\left[\left(\frac{D}{4R}\right)^2 - 1\right]$ assuming $G\nu_0 = 950$, from the first measurements. The line is completely determined by $G\nu_0$ since it cuts the horizontal axis at a distance $\frac{1}{3}$ from the origin and the vertical axis at a distance $-1/(G\nu_0)^2$.

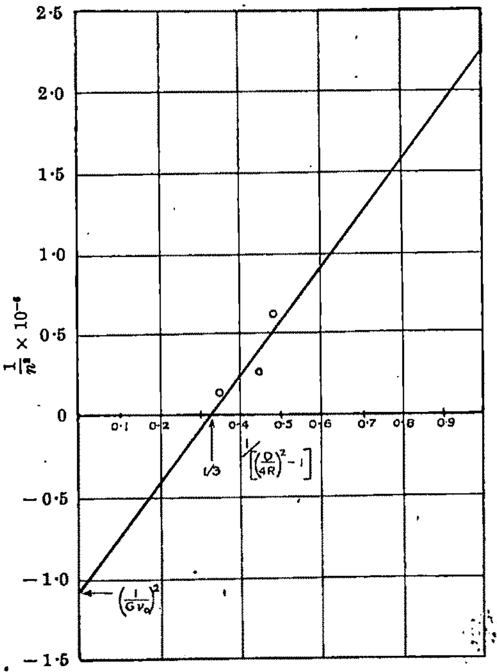

Fig. 2

Measurements of $R = M_{\text{oct}}/M$, with $P = 120$ kW. and $D = 60$ per cent, were made at $n/2\pi = 200$, 300 and 400 c./s., using a harmonic analyser.

Reference to Fig. 2 shows that the experimental points lie very near the line corresponding to $G\nu_0 = 950$; $\left(\frac{1}{(G\nu_0)^2} = 1\cdot1 \times 10^6\right)$. A third harmonic was also detected.

On the basis of these tests and of Bailey's theory, the modulation observed at Dundee is represented by the formula

$$M = 7\cdot8 \times 10^{-4} \frac{PD}{\sqrt{1 + \left(\frac{n}{950}\right)^2}},$$

where P is in kilowatts, M and D in percentages.

These investigations are of a preliminary character, and it is proposed to continue the work. From these results we estimate that if Stagshaw had operated on the gyro-frequency the impressed modulation at 100 c./s. would have been as great as 13 per cent with a transmitted power of 120 kilowatts. Such a station could, therefore, seriously interfere with other transmissions. We are indebted to Mr. J. A. Ratcliffe and Mr. S. J. Shaw, of the Cavendish Laboratory, for observing that the Droitwich transmissions were unmodulated before reaching Stagshaw.

We wish to express our appreciation of the assistance and co-operation we have received from Messrs. Kirke and Wilson, and in particular from Mr. R. A. Rowden, of the Engineering Research Department of the British Broadcasting Corporation.

Range-Energy Relation for Protons and α-Particles in the New Ilford 'Nuclear Research' Emulsions

WE have recently completed an investigation to determine the relation between the energy of protons, α-particles and other light nuclei and their range in the new Ilford 'Nuclear Research' emulsions[1]. A complete account of the experiments is now in the press[2], but in view of present delays in publication and for the convenience of other workers we wish to give a short account of the results.

The method employed was to determine the mean range in the emulsion of homogeneous groups of α-particles from the natural radioactive elements, and of protons from various well-known disintegration reactions. In the latter experiments, homogeneous beams of primary deuterons of known speed were employed, and the disintegration particles were observed in conditions of good geometry. It was thus possible to calculate the energy of the groups of particles, produced by various transmutations, from the known masses of the reacting nuclei. Experiments with targets of five of the light elements bombarded with 900 keV. deuterons enabled us to determine the range in the emulsion of twelve homogeneous groups of protons, of various energies in the interval from 2 to 13 MeV., and to construct a curve showing the relation between energy and range.

It is convenient to represent the results in terms of the mean stopping power of emulsion. This quantity, S, is defined as the ratio of the mean range in standard air of a group of particles of given energy to their mean range in the emulsion. In determining S from our observations, we used the values given by Livingston and Bethe for the ranges in standard air of protons of different energy.

In Fig. 1, Curve *a* shows the average stopping power of the B 1 type of emulsion for protons of different range. To determine the energy of a homogeneous group of protons of mean range, r, in the emulsion, the stopping power S_r corresponding to this range is found from the curve. The corresponding range in air, R, is given by the relation $R = S \times r$, and the energy, corresponding to this value of the range in air, can be deduced from the Livingston–Bethe curves. Curve *b* shows similar results for α-particles. In this case, in addition to the groups of α-particles emitted from samarium and from some of the heavy radioactive elements, we made use of the long-range α-particle group from the reaction Li$^6_3$ (d,α) He$^4_2$.

Although our observations are confined to the B 1 type of the 'Nuclear Research' emulsions, we believe

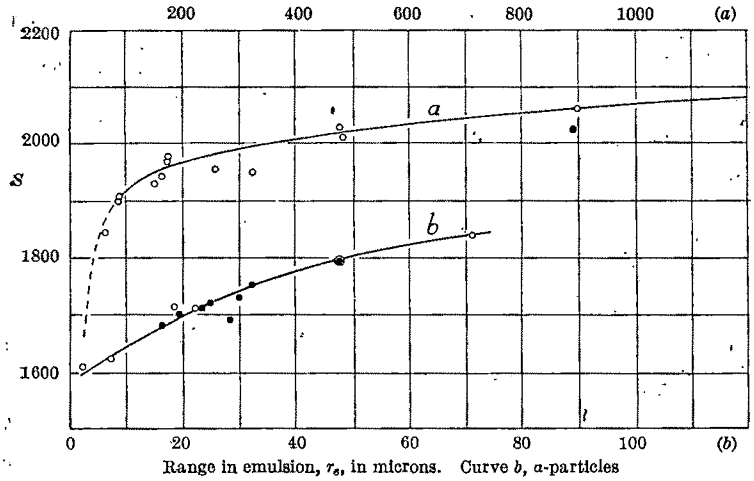

Fig. 1. ○, Present experiments; ●, Gibson, Green and Livesey's experiments

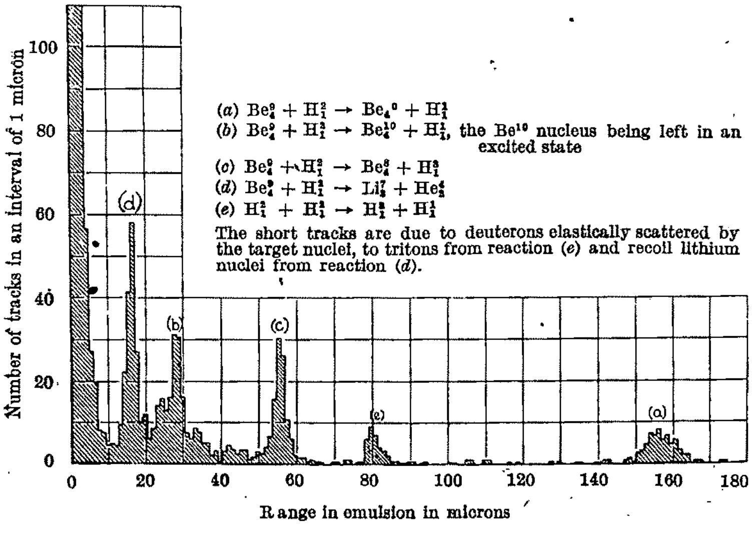
that the atomic composition of the other types, *C* 1, *C* 2, *E* 2, etc., is so nearly equal to that of *B* 1 that the present results may be generally applied without serious error. This view is strengthened by the results of experiments by Gibson, Green and Livesey with the *C* 2 emulsion, in which the ranges of α-particles from the heavy radioactive elements were determined. Points representing their observations are included in Curve *b*, and it will be seen that they are very close to those derived from the present experiments. According to the measurements of Tsien, Chastel, Faraggi and Vigneron[3], and to our own observations on the range of the α-particles of thorium *C′*, the *A* 1 emulsion has a slightly higher stopping power for α-particles than *B* 1 or *C* 2.

We may direct attention to two other features of the method in the conditions provided by the new emulsions.

First, as an example of its 'resolving power', Fig. 2 shows the distribution in range of 2,000 tracks, produced by the disintegration particles emitted from a thin evaporated film of beryllium bombarded by 900 keV. deuterons. The reactions giving rise to the particles composing the different peaks are indicated. The 'widths' of the peaks produced by the groups of protons are only a little greater than the value to be attributed to 'straggling', finite target thickness, etc. We may conclude that the precision with which the energy of a proton can be determined from the length of the track which it produces in the emulsion is now limited only by straggling.



(*a*) $Be^9_4 + H^2_1 \rightarrow Be_4{}^{10} + H^1_1$

(*b*) $Be^9_4 + H^2_1 \rightarrow Be^{10}_4 + H^1_1$, the Be^{10} nucleus being left in an excited state

(*c*) $Be^9_4 + H^2_1 \rightarrow Be^8_4 + H^3_1$

(*d*) $Be^9_4 + H^2_1 \rightarrow Li^7_3 + He^4_2$

(*e*) $H^2_1 + H^2_1 \rightarrow H^3_1 + H^1_1$

The short tracks are due to deuterons elastically scattered by the target nuclei, to tritons from reaction (*e*) and recoil lithium nuclei from reaction (*d*).

Secondly, the 'discriminating power' of the *B* 1 emulsion, although inferior to that of *C* 1 and *E* 1, is sufficiently great to allow us to distinguish the tracks of protons from those of α-particles of the same range. We are thus able to observe homogeneous groups of protons in the presence of α-particles, and to determine their mean range. As a result of the discriminating power of the emulsion we can show that peak (*b*) of Fig. 2 is due to protons. The mean range of the particles is such that they cannot have been produced by the disintegration of any of the light elements which might have been present as an impurity in the target. We therefore ascribe them to the reaction $Be^9_4 + H^2_1 \rightarrow Be^{10}_4 + H^1_1$, the Be^{10}_4 nuclei being formed in an excited state at 2·2 MeV.

We are indebted to Messrs. Gibson, Green and Livesey for permission to quote the results of the ranges of α-particles in the *C* 2 emulsion. We have pleasure in thanking Dr. Burcham and Mr. Livesey, who made it possible for us to obtain exposures to the beam of deuterons from the Cambridge high-tension generator.

Surface Formation of Lithium Negative Ions

Some years ago, Arnot[1] directed attention to the fact that bombardment of a surface with positive ions resulted in the liberation of negative ions of the same species. Shortly afterwards, Sloane and Press[2], using a double mass spectrometer and employing magnetic sorting of both the bombarding positive ion beam and the resulting negative ions, were able to prove that bombardment of a surface by positive ions of a given kind could result in the formation of a whole spectrum of negative ions.

We have recently bombarded a nickel surface with positive ions from a lithium thermionic source, and detected two peaks in the resulting negative ion spectrum due to ions with mass-to-charge ratios of 7 and 6 in atomic units. The ratio of the 7 and 6 peak heights in the spectrum is approximately 10 to 1, which is about what would be expected for the lithium isotopes. Both peaks contain ions with energies in excess of that imparted to them by the accelerating electric fields, a property which seems to be characteristic of negative ions produced by positive-ion bombardment of surfaces[1,2].

We also detected two negative ion peaks with mass-to-charge ratios 23 and 22, again with peak heights in approximately the ratio of the lithium isotopes. This ratio was maintained under different experimental conditions, although the relative intensities of neighbouring peaks at 24, 25 and 26 varied markedly. These observations suggest that 23 and 22 may be due to $Li_7O_{16}^-$ and $Li_6O_{16}^-$, an interesting possibility in view of the fact that 23, when reported before[3], has been attributed to Na^-. One of us (R. H. S.) and J. F. I. Cole recorded the 23 peak last year while bombarding a tantalum gauze with ions from a Kunsman sodium positive-ion source; but, because of its behaviour when experimental conditions were altered, hesitation was felt in attributing it to Na^-. It was always so small that the possible presence of 22 could not be checked.

These new results do not, of course, preclude the existence of a stable sodium negative ion; but they do appear to show that a negative ion peak at 23 can be due to a lithium compound, and that it is unwise to identify it as Na^- unless the peak due to 22 is simultaneously shown to be less intense than it would be if it were due to the compound containing the other lithium isotope.

In their important pioneer work on this subject K. S. Woodcock[4] and J. S. Thompson[5] bombarded surfaces with positive ions from a lithium source but did not record Li^-.

Uranium Not a Superconductor

It has recently been reported[1] that Justi has found uranium to become superconducting at 1·25° K. About a year ago, I looked for superconductivity in a very pure sample of uranium using the magnetic moment method. Below about 1·45° K. a slight diamagnetic effect appeared, as if about 0·5 per cent by volume of the metal had become superconducting; the critical field of this slight effect was about 210 gauss at the lowest temperature used (1·08° K.). Similar behaviour has previously been observed[2] for titanium and for a less pure sample of uranium, and it was then suggested that the slight superconducting effect is due to an impurity. The present results considered in conjunction with the chemical analysis of the sample suggest that the superconducting impurity may be uranium carbide, but I have not yet had an opportunity of testing this suggestion by direct investigation of a uranium carbide specimen.

It seems, then, that uranium is not a superconductor down to 1·08° K., and this illustrates the danger of drawing definite conclusions about possible superconductivity from resistance measurements alone (such as Justi used). A superconducting impurity, though only a small fraction of the volume, may shunt the bulk of the metal and cause the resistance to fall, but the magnetic moment provides a direct measure of the fraction which is superconducting.

Stabilizing Linear Particle Accelerators by Means of Grid Lenses

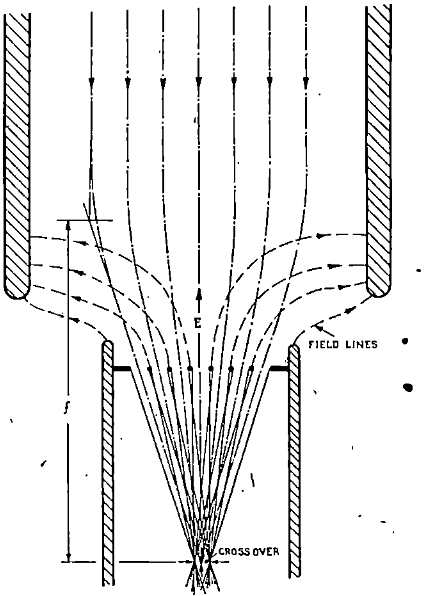
Though nothing appears to have been published, it is now fairly generally known that linear particle accelerators of the standing-wave type cannot be satisfactorily stabilized with electron lenses of conventional design for energies much exceeding about 10 MeV. I have confirmed this in an investigation starting from first principles, which showed also that lenses terminated at the exit end by a thin metal foil, such as the beryllium windows proposed by L. Alvarez of Berkeley University, promise satisfactory stability up to at least 1,000 MeV. On the suggestion of Prof. M. L. Oliphant, I extended the theory also to lenses in which the metal foil is replaced by a wire mesh grid or the like. 'Grid lenses' were investigated experimentally by Knoll and Ruska in the early days of electron optics, but they have largely fallen into oblivion. It appears now that they may well be revived for the concentration of the beam in linear accelerators, as they offer advantages equal if not superior to beryllium foils.

A gap open at one end and terminated at the other end by a conducting foil, with an electric field intensity E in the centre of the foil, acts as a condensing lens if E is accelerating. Introducing the foil produces an additional lens-power

$$\frac{1}{f} = \frac{1}{2}\frac{(1-\beta^2)^{1/2}}{\beta^2}\frac{eE}{m_0c^2},$$

where f is the focal length. As explained in the figure, this effect arises not at the foil, but by the divergence of the electric field at the other end. In the paraxial approximation it is independent of the shape of the foil.

If now the foil is replaced by a wire mesh grid or the like, with square or round holes, the beam is



FIELD AND ELECTRON TRAJECTORIES IN GRID LENS split up into a great number of fine pencils. In first approximation, each one of these pencils is collimated in itself; that is to say, within each mesh the lens effect produced by E is exactly compensated. But the global or macroscopic concentrating effect is by no means destroyed, as the central rays of the pencils suffer no deflexion. The effect of replacing the foil by a grid is merely that of replacing the point focus by a cross-over, which to a first approximation has the size and shape of a single grid hole. The next higher approximations (finite depth of the grid, lens effect quadratic in E, and spherical aberration) have all signs which point in a beneficial direction, that is to say, they tend to make the cross-over even smaller than a mesh hole.

With modern techniques it is possible to produce slat grids of a great variety of metals with clear areas of 98 and even 99 per cent, which can stand beam energies of several hundred watts per cm.^{2}. The danger of auto-electronic discharges starting from the sharp edges of the slats need not be very serious, as sufficient stability of operation can be obtained if the average field intensity E over the surface of the grid is only 10 per cent of the maximum or even less. Thus it appears that grid lenses may well compete with beryllium foils in the stabilization of linear accelerators for extreme energies.

I am indebted to Prof. Oliphant for his suggestion, and to the directors of the British Thomson-Houston Company for permission to publish this note.

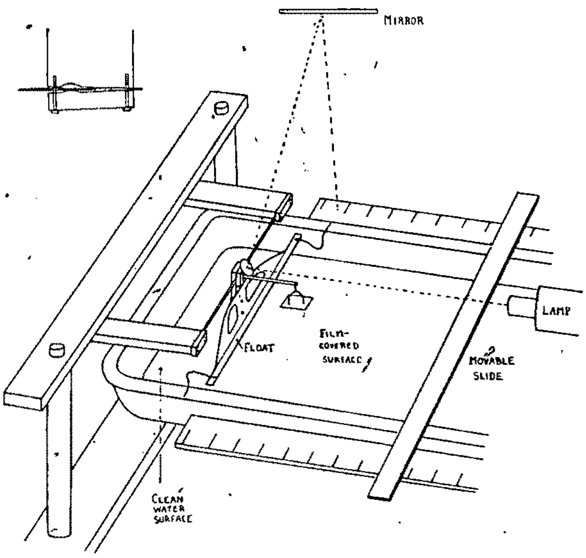
A Simple Film Balance for Demonstration and Research Purposes

The Langmuir–Adam film balance was developed to measure the lowering of surface tension (termed the surface pressure) produced by paraffin-chain compounds such as oleic acid when spread as monolayers on aqueous solutions. With substances giving condensed films (for example, stearic acid, cetyl alcohol) the sudden lowering of surface tension when the molecules are squeezed into close-packing provides a striking lecture demonstration, and many simple experiments illustrating molecular orientation, changes of phase and physical state in two-dimensions, etc., can be demonstrated by this means. In addition, the film balance has been widely applied for research purposes, particularly to problems of colloidal systems, such as foams, emulsions, proteins and polymers; to structure determination of complex organic molecules, and recently to surface-area determination of fine powders by adsorption of long-chain polar compounds from organic solvents.

To cater for the greatly increased interest in surface chemistry, the present type of film balance was devised. In addition to simplicity of construction it has some advantages over the usual type employing a torsion balance. The principle can be seen from the accompanying figure.



The monolayer is merely compressed by the usual waxed glass slide against a relatively stout torsion wire, or better, a thin metal strip (the use of a strip is preferred as it automatically brings the float to a fixed position), and the resulting deflexion of the float amplified optically as shown. The reflecting mirror shown at the top of the figure is located by means of a tall stand almost vertically above the far end of the torsion arm. A two-metre optical path has been found convenient for ordinary purposes. One of the horizontal scales used to indicate the position of the movable barrier also serves to measure the optical deflexions and hence the force on the float. Errors in film area due to the movement of the float are usually negligible (they can be allowed for if necessary), since this movement is deliberately kept very small. With a distance of 2 cm. between the torsion wire (strip) and the float, 1 mm. movement corresponds to 20 cm. deflexion at 2 metres. The torsion wire or strip is suitably chosen so that the float movement does not exceed c. 1 mm. for the maximum surface pressures encountered. Thin steel watch spring has been found very suitable for the usual film pressures, that is, of the order 10–50 dynes/cm. The torsion wire or strip can readily be changed merely by loosening the simple clips at its ends, and no difficulty in tightening it sufficiently has so far been encountered, but if necessary the device shown inset can be used.

The float consists of thin duralumin (or other metal) sheet, turned up at the edge and screwed to the vertical duralumin bar to which the torsion wire or strip is clamped. For research purposes a thin mica strip is attached by wax beneath the float to keep all metal out of contact with the solution. A rectangular 'Pyrex' baking-dish, or the glass dish used in 'Frigidaire' refrigerators, provides an excellent trough after the bevelled edges have been ground flat.

Calibration can be carried out in the usual way by adding weights to the small pan (a light wire ring and piece of paper) shown in the figure, or by spreading 'piston oils', such as castor oil or oleic acid, which give known surface pressures.

This apparatus appears to give an accuracy fully equal to that of the usual torsion balance, with the additional advantage that measurements can be carried out much more rapidly. It can also be used for automatic recording of force-area curves, and in addition can readily be adapted to measure surface or interfacial tensions.

Reflectivity of Steel

THE method briefly described in these columns[1] some time ago was employed in an investigation of the reflectivity of two kinds of steel at different temperatures. The two specimens were 'stainless' steel, and no special precautions were taken to ensure an oxide-free atmosphere. Their composition was as follows: *SF*11, 13 per cent chromium; *SF*20, 18 per cent chromium, 8 per cent nickel. The measurements were carried out for two wave-lengths, 0·55 and 0·65 μ, and extended over a range of more than 300° C. The room-temperature results are listed in Table 1.

TABLE 1. REFLECTIVITY IN %

λ	0·55μ	0·65μ
*SF*11	50·1	54·5
*SF*20	64·8	66·4

Those for *SF*20 belong to the highest found in the literature, being in fair agreement with the values obtained by Pfestorf[2] (on Krupp *V2a* Edelstahl). Generally, it is impossible to carry out any comparisons, since few authors give adequate data on the composition of their specimens. The temptation to ascribe the higher reflectivity of *SF*20 to its nickel content must be resisted: in some comprehensive work which covered the visible and ultra-violet parts of the spectrum, von Fragstein[3] has found it impossible to detect any systematic variation in the reflectivity with the composition of his steel specimens. Such a variation is only likely to be found in the far infra-red.

The temperature coefficient of reflectivity is defined by

$$\alpha_\lambda = \frac{1}{R_\lambda} \cdot \frac{dR_\lambda}{dT}.$$

The values obtained in the present investigation and given in Table 2 refer to room-temperature. Since dR/dT is less dependent on the manner in which the mirror has been prepared than α, the values for the gradient proper are also presented.

TABLE 2

	0·55 μ		0·65 μ	
	dR/dT	α	dR/dT	α
*SF*11	$+1{\cdot}43\times10^{-2}$	$+2{\cdot}8\times10^{-4}$	0	0
*SF*20	$+3{\cdot}75\times10^{-3}$	$+5{\cdot}78\times10^{-4}$	$+7{\cdot}5\times10^{-3}$	$+1{\cdot}13\times10^{-4}$

As might have been expected, the mirrors tarnished when high temperatures were employed. It was interesting to observe that the reflectivity on the short wave-length side of the spectrum decreased before that near the red end. A comparison with the work of Banning[4] and Sabine[5] shows that, in the case of aluminium, the ultra-violet reflectivity is greater for the specimen which had not been exposed to air before measurements were taken. Since the reflectivities of pure aluminium and its oxide are practically the same in the visible region, it is possible to assume that the oxide layer formed by the atmosphere on the aluminium is extremely thin. This has been accounted for theoretically by Mott[6]. It would then appear that the thickness of the film in the case of steel is such as to reduce the reflectivity in a manner analogous to that of aluminium, except that the diminution occurs in the visible region. It is likely that such a film is only a transitional phenomenon for, when the mirror was heated to a temperature of more than 500° C., it turned blue. It is assumed that the predominant reflectivity of the red in the early stages is due to the film being opaque to wave-lengths shorter than these, and that the blue appearance later is due to interference phenomena in the thicker film itself.

Lastly, it is seen that $\alpha_{0\cdot65\mu} = 0$ for *SF*11. Such a point has been termed an X-point by Price[7], and is said to be characteristic of each metal. While its significance from the point of view of pyrometry cannot be over-estimated, especially if this coefficient should be zero over large temperature ranges, it is not thought that it has any fundamental value. Its existence can be predicted at least qualitatively on the basis of classical electro-magnetic and electronic theory. A complete analysis of this fact will be given on another occasion.

The above work has been carried out under the auspices of the Pyrometry Sub-Committee of the British Iron and Steel Research Association. I am indebted to the Committee for permission to publish this account, and to Mr. W. C. Heselwood, of the United Steel Companies, Ltd., Sheffield, for the supply of the specimens.

Choice of a 'Reality Index' for Suspected Cyclic Variations

IN *Nature* of December 21, Dr. W. Gleissberg proposes an index R for estimating the reality of cyclic variations in a series of observations. This index involves the average length L of a 'run' and the standard deviation S, about this mean, as calculated by Kermack and McKendrick[1]. The object of this communication is not to discuss the arguments for or against the proposed index, but to point out an error of a somewhat subtle type which occurs in the example given by Dr. Gleissberg. Figures are given representing the heights of sunspot maxima for 18 consecutive periods. The mean length of the runs, L, is 2·4, which is very close to the theoretical mean, 2·5. Consequently the reality index, $R = D^2/D^2+S^2$, where $D = L - 2{\cdot}5$, is small. So far as this test goes, the fluctuations may well be random ones and not dependent on 'real' cyclic variations.

In order to eliminate accidental or experimental errors, Dr. Gleissberg proceeds to take running averages of the observations in groups of four, the first group consisting of the first four observations a, b, c and d, the second of b, c, d and e, the third of c, d, e and f, and so on. In this way he obtains fifteen averages each of four observations, and goes on to calculate the value of the reality index R for this derived set. The mean length L is found to be 3·8, which exceeds 2·5 by 1·3, a quantity very large in comparison with the standard deviation, and R comes out very nearly unity.

A little consideration shows that this calculation is quite inappropriate for a series derived, as above, by forming running averages. The mean length of a 'run' L is 2·5 in an infinite series, n_1, n_2 . . ., n_x . . ., of, say, random decimals between 0 and 1. But the numbers derived from such a random series by taking running averages of groups of t or, what for present purposes is essentially equivalent, taking the sums $\sum_{x=1}^{t} n_x$, $\sum_{x=2}^{+1} n_x$, . . . $\sum_{x=m}^{t+m-1} n_x$, no longer form a random series, and the average length of a 'run' is no longer 2·5. It is not difficult, in fact, to show that, whatever t may be, the average length of a 'run' is 3·0, except in the special case when $t = 1$. The following does not claim to be strictly rigorous.

First take the exceptional case $t = 1$. Any number in a series of random numbers is a 'maximum' when it is greater than the preceding and succeeding numbers. But by hypothesis these are three numbers taken at random, and the probability that of three such numbers the middle one should be the greatest is clearly $\frac{1}{3}$. Thus the probability that any number in the series should be a 'maximum' is $\frac{1}{3}$. Similarly, the probability that any number should be a 'minimum' is also one third. If we have a long series containing N numbers, there will be approximately $2N/3$ 'extrema' ('maxima' and 'minima'), and it follows at once that the average length of a 'run' is 2·5, the length as explained in Dr. Gleissberg's letter being the number of numbers in the 'run', including the first and the last.

Let us now take $t = 4$; it is easily seen that the argument holds when $t \geqslant 2$. If the original series is $a, b, c, d, e, f, \ldots$, the derived series is $(a+b+c+d)$, $(b+c+d+e)$, $(c+d+e+f)$ . . . Clearly the middle term will be a 'maximum' provided e is greater than a and b is greater than f. But there is a probability of each of these conditions being fulfilled of $\frac{1}{2}$, and the two events are independent as the original series is a random one, and so the probability of the two events occurring together is $\frac{1}{4}$. Thus in the derived series one quarter, and not one third, of all the numbers are 'maxima', and one quarter are similarly 'minima'; one half of all the numbers are 'extrema'. It readily follows that the average length of a 'run' is now 3 and not 2·5. The standard deviation of the lengths of 'runs' about the mean length would presumably differ from the special case where $t = 1$, but its calculation would be more involved.

To test these results, the first two hundred of Fisher and Yates' random numbers were taken from their tables (Statistical Tables for Biological, Agricultural and Medical Research). These numbers each contained only two digits, and this means in effect that we are limited to a hundred different numbers instead of an infinite population. However, the deviation from the theory occasioned by this limitation is but slight. Where two consecutive numbers are equal, they were counted as one 'extremum'.

It was found that the series of two hundred numbers contained 129 'extrema'. Taking $t = 2$, that is, the series $(a+b)$, $(b+c)$, $(c+d)$ . . ., etc., the number of 'extrema' was 96. Taking $t = 4$, that is, the series $(a+b+c+d)$, $(b+c+d+e)$ . . ., etc., the number of 'extrema' was 94. These results may be compared with the expected values of $\frac{2}{3}$ $(200-2) = 132$ in the case of the series of two hundred numbers (the first and last of the two hundred numbers are excluded in the calculation as they cannot figure in 'extrema'), 98·5 in the case of $t = 2$ and 97·5 in the case of $t = 4$. Clearly, for $t = 2$ and $t = 4$, the number of 'extrema' found agrees closely with that required by the above theory, but differs considerably from what would be expected in a really random series.

The above considerations do not disprove Dr. Gleissberg's final conclusion that there is an underlying cyclic variation in the sunspot maxima, obscured by some random effects; but they do suggest that this particular application of his reality index is not rigorously sound. If this, or any similar index, meets with general acceptance, it is important that the conditions under which it can be applied should be adhered to.

Spiral Cracks in Glass Tubes

I believe that the interesting experiments recently reported in *Nature*[1] cannot, for symmetry reasons, be explained on the ordinary theory of strength of homogeneous materials; but an attempt at a qualitative study of the spiral cracks according to Griffith's views on the phenomena of rupture[2] may be developed as follows.

If we assume that at normal temperature 'Pyrex' glass possesses some kind of porosity with a random distribution of small spherical cavities, the surface tensions acting along these inner boundaries oppose themselves to thermal dilatation and, consequently, in heated glass, many spherical cavities will be deformed into ellipsoids. Both eccentricity and stress concentration at the ends of the major axis will increase with temperature.

As in rapid breakings the hypothesis of fracture propagation in the direction of maximum strain seems quite admissible, we have to calculate the most unfavourable orientation of the major axes of the cavities from which the cracks will start. To a first approximation, we can consider a plane plate with elliptic holes of given average eccentricity undergoing a tensile stress, and keep the deductions valid for the external layer of the annealed tubes.

Denote by φ the angle between the direction of stress S (at infinity) and the major axis of the hole; then the extension L of the axis can be expressed in the well-known form: $L = S\,(A\cos^2\varphi + B\sin^2\varphi + 2C\sin\varphi\cos\varphi)$, where A, B are coefficients of elasticity for tensile stresses parallel to the axes of the ellipse, and C (the value of which is not strongly influenced by eccentricity) is the analogous coefficient for a pure shearing stress.

L is a maximum in the directions determined by the equation: $tg 2\varphi = 2C|(B - A)|$.

Now, the difference $|(B - A)|$ depends upon eccentricity and increases with temperature: hence φ and the helix pitch decrease; moreover, L, too, increases with temperature, and so does its derivative with respect to φ; $L_{\text{max.}}$ is more sharply defined, and this explains why at high temperature the cracks are more regular; their finer structure may be caused by the rapidity of formation, as for dynamical compression tests on paraffin at normal temperature[3].

At still higher temperature, φ becomes very small and possibly less than the limits determining the phenomenon; in this case the crack is closed and we have segmentation.

Finally, at low temperature, φ should approach 45°; but during the same time, the variations of L with respect to φ greatly diminish, rupture is no longer very rapid and it occurs statically (along a generatrix) rather than dynamically (at 45°); so we only have straight or steep wavy lines.

Electrogenic Properties of Acetylcholine

FOLLOWING the classical work of Dale on acetylcholine, numerous investigators have demonstrated the important part played by this quaternary amine in the nervous system[1]. A neglected property of acetylcholine is its extraordinary electrogenic action at the phase boundary between oils and aqueous solutions[2]. This negative phase boundary potential provides a possible explanation of the electrical component of the nerve impulse in cholinergic nerves[3]. It seems reasonable to suppose that the action potential[4] might arise from the contact of acetylcholine with the lipoid layer of the nerve fibre according to the theory of phase-boundary potentials[5]. Moreover, it has been shown that acetylcholine produces a negative electrical potential on living frog skin[6].

The penetration of acetylcholine into an oil layer can be determined by measurements of the fall in resistance of oil in contact with solutions of acetylcholine in physiological saline. For E.M.F. studies, equal parts of cholesterol are added to the oil, but for conductivity measurements more uniform results are obtained with a pure solvent. Guaiacol[7] has several properties found in protoplasm, such as its conductivity, and the property of distinguishing between potassium and sodium and, above all, absorbing lipoid-soluble substances. 20 c.c. samples of guaiacol were shaken for five hours with 100 c.c. samples of the aqueous solutions. In a typical experiment (at 25° C.) the oil had a specific resistance of 140×10^4 ohms after shaking with saline; 25×10^4 ohms after shaking with 50 mgm. per cent acetylcholine in saline; 19×10^4 ohms after shaking with 100 mgm. per cent acetylcholine in saline; 10×10^4 ohms after shaking with 200 mgm. per cent acetylcholine in saline.

The measured phase-boundary potential of 50 mgm. per cent acetylcholine in saline in contact with guaiacol was 35 mV. (negativity), which is close to the value of 45 mV. calculated from the above data. According to the Nernst equation, the potential can be calculated as the logarithm of the difference in concentration of the common ion (difference in conductivity of oil in contact with sodium chloride and in contact with acetylcholine chloride—a seven-fold difference) multiplied by the factor 0·058 for room temperature.

The fall in resistance of nerve during activity might be explained as the fall in resistance of the nerve lipoid layer produced by the penetration of acetylcholine. There is no longer need to postulate the breakdown of an imaginary Bernstein membrane[8].

If an electroencephalograph is employed instead of the usual potentiometer to measure the electrical change produced by adding acetylcholine to an oil layer, it is found that the negativity rises very rapidly, resembling the upstroke of the spike potential in nerve. The downstroke of the spike potential in nerve might be produced by the acetylcholine reaching the opposite side of the extremely thin oil layer at the surface of the nerve fibre. There is also the possibility that the enzyme choline esterase[9] destroys the acetylcholine potential, thus forming the downstroke of the spike potential in nerve. Acetylcholine solutions were shaken with esterase preparations and the potentials measured at an oil boundary. In a typical experiment, two 200 c.c. samples of saline containing 50 mgm. per cent acetylcholine with 100 mgm. per cent bicarbonate and 6 gm. of minced fresh cat brain (cortex) gave phase boundary potentials of 7 and 3 mV. negative in contact with 10 per cent cholesterol in guaiacol, compared with 32 and 29 mV. negative given by two control solutions of identical composition but containing no brain substance. 200 c.c. of saline with 100 mgm. per cent bicarbonate but no acetylcholine or brain and shaken for the same time (5 hr.) gave a potential of 7 mV. positive. 1 mgm. per cent eserine and also 0·05 per cent di-isopropyl fluorophosphate preserved the electrogenic properties of acetylcholine solutions in the presence of esterase; but other workers[10] have found that these anti-esterase agents fail to prolong the spike potential in nerve, showing that esterase is not essential for the formation of the electrical nerve impulse. In living cholinergic nerve, esterase probably has a minor function of removing excess acetylcholine.

Partition-Chromatography and Living Cells

CHROMATOGRAPHY appears likely to play an important part in future work on protein analysis. The partition method[1,2], whereby amino-acids can be separated and identified on a cellulose strip, is sensitive to extremely small amounts of material. For example, 1 μgm. of an amino-acid gives a clearly visible colour reaction with ninhydrin. The method may ultimately, therefore, prove valuable for the protein analysis of the chromosomes and their products. With suitable solvents and developers, it should be possible to separate and determine the nucleic acids, as well as amino-acids. In our preliminary experiments, the method has been used to survey the presence of free amino-acids in plant and animal tissues at different stages of nuclear activity.

The following tissues have been tested: salivary glands of *Drosophila*, root tips of *Trillium*, anthers of *Tradescantia* at various stages of meiosis and pollen formation, and the white and yolk of a hen's egg.

Small amounts of the tissues and separated egg were smeared direct on to filter-paper strips; the crushed root tips being attached by means of a starch support. As a check on the possibility of protein degradation after death, a duplicate smear of each cell type was fixed by flooding with ethyl alcohol; but no difference in results was found. The paper strips were run in one dimension only, using water-saturated phenol as the solvent. The air-tight chamber in which separations were carried out contained a two-phase solution of water and phenol at the bottom. After 24 hours treatment, the filter-paper strips were dried in a water-oven at 98° C., sprayed with ninhydrin and dried again in the oven to allow the colour spots to develop. Only two kinds of result were obtained: (1) no coloration (that is, no free amino-acids): salivary glands and white of egg; (2) two or more colour bands indicating the presence of two or more free amino-acids: all the plant cells and yolk of egg.

The nature and exact location of the free amino-acids is at the moment a matter for speculation. Previous work by the use of other methods has already shown them to be present in plant tissues[3]. Whether their absence in salivary glands can be attributed to the absence of mitosis remains to be shown.

Metabolism of Fatty Livers

Earlier work on the metabolism of fatty livers by Ennor[1] showed that the oxygen consumption and the acetoacetic acid production of liver slices from guinea pigs poisoned with carbon tetrachloride is considerably in excess of normal. Since adenosinetriphosphate is essential for the oxidation of fatty acids[2], it was considered of interest to determine a possible correlation between high-energy phosphate content and the increased metabolism of such livers.

0·1 ml. of carbon tetrachloride in arachis oil was given by subcutaneous injection to well-fed guinea pigs of approximately 300 gm. body-weight. Two to four doses were given at 24–48 hour intervals, and both control and treated animals were starved for 24 hours before killing. The major portion of the liver was dropped into liquid air within 30 sec. of the death of the animal; the remainder of the liver was taken for fat, nitrogen and total phosphorus determinations. Duplicate samples of the powdered, frozen liver were extracted twice with trichloracetic acid and, after removal of the protein, aliquots were taken for an analysis of the barium-insoluble fraction precipitable at pH 8·2. Determinations were made of the inorganic phosphorus originally present and that released on heating at 100° C. in *N* sulphuric acid for varying time intervals up to three hours. All figures are calculated on the basis of the nitrogen content of the original liver.

From the accompanying table it will be seen that the readily hydrolysable phosphorus (7 min.) is higher in the livers of the treated animals than in the control series. The relative amounts of adenosine di- and tri-phosphates present in this fraction have not been fully established; but it is of interest that the increase, due primarily to the presence of these compounds, is associated with the increase in metabolism found in fatty livers of this type.

Mechanism of the Action of X-Rays on Enzymes in Water-Solution

It is a well-established fact[1] that the action of ionizing rays on substances dissolved in water often proceeds in a way suggesting an interaction of some irradiation products of the water molecules. As regards the nature of these hypothetical intermediary products and the mechanism of the action on the dissolved substances, Weiss[2] has discussed the possible formation of H-atoms and OH-radicals. The biological significance of the reactions has also been tentatively discussed. If a second component is added, the action of X-rays on the substance under consideration may change owing to dissipation of the primary X-ray products between the two substances.

Some experiments may further elucidate the mechanism. The X-ray dose given was 12·400 r., the intensity 275 r./m. The enzyme studied here was pure crystalline catalase[3] diluted to a concentration of $3{\cdot}7 \times 10^{-6}$ gm./ml. The experiments were run at pH 7·4 and in an atmosphere of nitrogen in order to avoid the interaction of gaseous oxygen; 6–12 tests were used for each substance (see accompanying table).

Substance added (conc. 0·1–0·2 m*M*.)	Inactivation (per cent)
Enzyme alone	53·9 ± 1·4
Maleic (fumaric) acid	30·9 ± 3·2
Malonic acid	54·3 ± 2·1
Succinic acid	53·1 ± 0·9
Pyruvic acid	40·8 ± 1·7
Lævulinic acid	46·3 ± 3·6
Glutathione	71·0 ± 3·7
Oxidized glutathione	30·2 ± 1·3
Cysteine	67·5 ± 7·4
Cystine	28·6 ± 1·4

Unsaturated substances, which may be expected to react with the water products (for example, fumaric and maleic acids), act as protective systems. Related saturated acids (malonic and succinic acids) show no signs of influence, whereas ketocarbonic acids, for example, pyruvic and lævulinic acids, are protective (the latter in a less pronounced manner).

Some of the other experiments reported in the table are more instructive as to the mechanism of the reaction. Glutathione (cysteine) increases, whereas oxidized glutathione (cystine) decreases the action of X-rays; for this we suggest the following explanation. Suppose the water is primarily split into H-atoms and OH-radicals. In the presence of glutathione (or cysteine) the reaction $2RSH + OH \rightarrow 2RSSR + H_2O + H$ may occur to some extent, thus increasing the chances of a reaction between the enzyme and the H-atoms. In the presence of the oxidized product, the reverse takes place. According to this conception the action will *in this instance* be exerted by free H-atoms. The protection of the ketocarbonic acids may then be considered to depend on a reduction of these substances. Another X-ray reaction may be mentioned in this connexion. Fricke[4] has shown that pure water is not measurably decomposed by X-rays, but it is in the presence of small amounts of iodine ions (1·0–0·01 millimol.). Formation of hydrogen peroxide, and in unbuffered or alkaline solution also oxygen, that is, oxidizing products, can be proved. It is conceivable that the presence of iodine ions will decrease the amount of free hydrogen atoms. Now the addition of such quantities of iodine ions affords a very strong protection for the catalase against the X-rays, so that doses up to ten times as big must be given in order to obtain the same effect as without the iodine ions.

Action of Light upon Jute

THE treatment of jute with certain alkylating and acylating agents inhibits the discoloration which this fibre, in common with most ligno-cellulosic fibres, undergoes on exposure to light[1,2].

One approach to a better understanding of the factors involved in the discoloration and in its prevention is afforded by a study of the chemical reactions which take place on irradiation. Samples of jute yarn and powder have been exposed to the light of a quartz mercury-vapour lamp; the yellow-brown colour produced is the result of two or more reactions leading to the formation of yellow and brown reaction products. A large part of these derivatives is soluble in water, and the yellow to brown colour of the solution is intensified on addition of alkali but reduced by the action of sulphur dioxide. It is clear that the soluble, coloured reaction products are of relatively small molecular weight and that they are derived mainly from the ligneous encrusting materials, though degradation products of the hemicellulosic constituents may also be involved. Irradiation leads to a reduction in the yield of lignin-forming units and a reduced yield of furfuraldehyde. Furthermore, the methoxyl content of lignin isolated from irradiated jute is lower than that of the comparable fraction from a non-irradiated sample. Demethoxylation of the lignin-forming units to polyhydroxy phenolic fission products, which are converted to quininoid forms, and the formation of furfural polymers or furfural-phenol condensation compounds, are held to be the sources of the coloured derivatives.

The formation of these coloured compounds can be prevented either by removal of the lignin or by acetylation. Methylation with an ethereal solution of diazomethane only partially inhibits the reactions. Irradiation of an acetylated sample results in a loss of acetyl groups, the major portion of which can be recovered as free acetic acid, though the presence of a small amount of bound acetic acid, liberated after hydrolysis with potash, has been noted. It is concluded that irradiation of acetylated and methylated jute produces substituted polyhydroxy phenols which are incapable of forming coloured quinones. The bleaching of acetylated jute, which occurs on irradiation, is not observed with methylated jute. This is probably due to the labile acetyl groups forming a bleaching agent such as acetyl peroxide, which has been shown to bring about the bleaching of acetylated jute. Acetylation, as an aid to colour inhibition, appears, therefore, to have the two functions of preventing quinone formation and causing the production of a bleaching agent during irradiation.

I wish to thank the Indian Jute Mills Association Research Institute for permission to publish this note.

Artificial 'Breaking' of the Diapause in *Drosophila nitens*

LABORATORY strains of *Drosophila nitens* Buzzati-T., though kept under constant conditions of temperature and lighting, are known[1] to undergo a winter diapause (November–March) at the imago stage. A few individuals reproduce in winter, but at a very slow rate. This was a handicap to genetical studies on this species.

It is known that various external stimuli may 'break' the diapause of the insects, although the mechanism of their action is not completely understood[2]. Our experiments showed that individuals of *Drosophila nitens* exposed to low temperature (ten days at 2–5° C.) one month from the beginning of the diapause, after which they were kept again at 25° C., are induced to 'break' the diapause and reproduce actively. Egg-laying is high; the larvæ develop at a normal rate; the adults emerged reproduce again, as if the winter period had been overcome.

From an ecological and physiological point of view, it will be interesting to see when the treated strains will undergo the diapause again, since their reproductive period began precociously: that datum will be of importance in seeking causes of the seasonal cycle of the species.

A CONTINUUM THEORY OF RHEOLOGICAL PHENOMENA

By Dr. K. WEISSENBERG

When materials of different kinds are subjected to mechanical actions we may observe a great variety of rheological phenomena, and we shall confine our attention here to a certain group of them which allows a theoretical and experimental investigation on a macroscopic scale. Here then, as in the classical theories of elasticity and hydrodynamics, we can treat the materials as continuous media, and the forces and displacements as vectors which vary continuously in space and time.

Let us consider first what happens in an appropriately chosen cycle of rheological states. We start with a material in a *ground-state*, that is, in a state in which every portion is at rest and free from external forces. We then impose some mechanical action and thereby bring the material into the particular *energized* state the phenomena of which we want to investigate. Finally, to complete the cycle, we suddenly release all external forces and allow the material to drift back into some ground-state (which may or may not be the one from which it was started). We can now define as a characteristic parameter of the energized state considered, and of the phenomena produced therein, the *recoverable strain*, that is, the amount of strain recovered after the release of the forces.

An experimental investigation was carried out under Dr. C. H. Lander[1], and in this we found it convenient to classify a material as *stable* if it regains always the same mechanical properties after completing a cycle from one ground-state to another, and to refer to it as *general* or *special* in some range of rheological states, according as the recoverable strain reaches in that range finite values, or remains infinitesimally small or zero throughout. The investigation covered a wide range of stable materials comprising such solids and liquids as are homogeneous and isotropic in all their ground-states. It revealed the differences in behaviour between general and special materials rather strikingly under certain conditions, as is illustrated in Fig. 1 for liquids, that is, for materials which flow under any shearing stress, however small.

The experimental arrangement is such that the liquid is sheared in a gap between an outer vessel rotated with an angular velocity that is kept constant at various levels, and an inner member which is held against rotation and either rigidly fixed in position or free to move up and down the axis of rotation. The conditions are so chosen that under the combined actions of the shear imposed at the boundaries, and the forces of gravity and inertia (centrifugal forces), the liquid executes a stationary laminar shearing movement.

An analysis of the experimental results shows that in such a motion the stress has its strength so distributed over the various directions in space as to comprise, in addition to the shear stress components, a pull along the lines of flow. We obtained direct experimental evidence for the presence or absence of such a pull by suddenly stopping the motion, and then making cuts perpendicular to the lines of flow. The general liquid used had a time of relaxation sufficiently long for the stress to persist appreciably after the stoppage, and the pull component present in this stress caused the cuts to open up. This pull distinguishes the general liquids from the special ones, being of finite amount or infinitesimally small when the recoverable strain is finite or infinitesimal. (Liquids which are in a certain range 'general' must in the same range be 'non-Newtonian' or 'anomalous'; while liquids which are 'special' may be 'Newtonian' or 'normal', but need not be so.) If, as in our experiments, the lines of flow are closed circles, the pull along these lines strangulates the liquid and forces it inwards against the centrifugal forces and upwards against the forces of gravity. The presence and absence of such a strangulation is illustrated in Fig. 1 under the column divisions headed respectively "General Liquids" and "Special Liquids". I am greatly indebted to Dr. Lander and to his collaborators, Dr. P. Rosin, Dr. H. Fehling, Mr. M. Deutsch and Mr. R. J. Russell[2], for the generous help they gave me in these experiments, and to Mr. S. M. Freeman for many improvements in the experimental technique. My thanks are also due to Dr. F. H. Garner and Dr. A. H. Nissan who, on being informed of the results obtained and while continuing their own lines of research[3], suggested a useful arrangement of pressure gauges (see Fig. 1, row 6).

7 NON-ROTATING DISK (variable bottom gap)
MAXIMUM SHEAR STRAIN RECOVERY IN GIVEN RANGE OF CONDITIONS ⇨
GENERAL (any finite value)
SPECIAL (infinitely small value)

Fig. 1. FLOW OF LIQUIDS UNDER ACTIONS OF STATIONARY SHEAR IN GAPS

A continuum theory was developed for the rheological states of general and special materials, along the lines of the classical treatment of elastic continua. As a first approximation a theory was proposed[4], containing an arbitrarily assumed law of elasticity, and from this theory predictions were made for a pull along the lines of flow and for a great variety of rheological phenomena, including such as are reproduced in Fig. 1. The experimental investigation under Dr. Lander (1943–45) then revealed that in a variety of materials, including saponified oils, solutions of rubber, starch, cellulose acetate, etc., the predicted phenomena actually occur, but with a systematic discrepancy between the strength of the stress components anticipated in the various directions of space and that actually found in quantitative measurements. The discrepancy was rectified, and full agreement reached with all experimental results obtained so far, in a revised theory, in which the arbitrarily assumed law of elasticity was replaced by an empirical law of the form

$$\frac{P_{au} - P_{bv}}{R_{au} - R_{bv}} = \frac{P_{bv} - P_{cw}}{R_{bv} - R_{cw}} = \frac{P_{cw} - P_{au}}{R_{cw} - R_{au}} = G(P, R) \quad (1)$$

Here—for the energized state considered—we denote by P_{kl} the *kl* component of stress, by R_{mn} the *mn* component of the recoverable strain, measured on the classical scale as the elongation ratio squared minus unity, by *a*, *b*, *c* and *u*, *v*, *w* the numbers 1, 2, 3 or any cyclical permutation of these numbers, and by $G(P, R)$ a function of the three fundamental scalar invariants of stress and strain, and other scalar parameters such as temperature, time, etc. The function $G(P, R)$ may be regarded as a generalized modulus of elasticity, the value of which may vary with the material and the rheological state, the temperature, time, etc. This is best seen when the empirical law (1) is specialized for the case of a stationary laminar shearing movement, where the suffixes 1, 2 and 3 correspond respectively to the directions of the lines of flow, the perpendicular to the shearing plane, and the normal to both these directions, and where the recoverable strain has components R_{mn} which are all zero, except R_{11}, R_{12}, and R_{21}, with $R_{11} = (R_{12})^2 = (R_{21})^2$.

Recently, further progress was made[5] when we succeeded in replacing the empirical law of elasticity (1) by a simple theoretical assumption. We consider an elastic continuum in any energized state, and imagine it cut into two parts by a plane drawn in any direction through some arbitrarily selected point. For every such plane the traction force will define a triad of mutually perpendicular directions, according to its normal, tangential and cross-components; and a second triad is defined by taking similar components of the displacement of the two parts relative to one another when the continuum recovers to a ground-state. We can formally deduce equation (1) from the assumption of a coincidence of these two triads of directions for every plane. This assumption, and the elasticity law derived from it, have been confirmed empirically over wide ranges of materials and mechanical actions; but further experimental investigations are required, and are in fact under way, to ascertain the exact limitations of validity, since a theoretical proof can be given only under certain conditions. Keeping within the range of elastic continua which are isotropic in all the ground-states, we can prove the validity of the assumption (*a*) in all classes of rheological states for certain orientations of planes, and (*b*) for all possible orientations of planes in certain classes of rheological states, including all classes restricted either to infinitesimal small strains, or to any stresses and strains with cylindrical symmetry.

EMERGENCY SCIENTIFIC RESEARCH BUREAU, EIRE

THE report of the Emergency Scientific Research Bureau, Eire, covering the period February 21, 1941–March 31, 1945*, which was set up with Prof. J. J. Dowling as chairman, gives brief details of the work of the Bureau.

A large part of the Bureau's experimental work dealt with fuel problems, and the most important of these included the manufacture of charcoal from turf, the efficiency of mobile producer plants, and the production of town gas under emergency conditions. Work on the production of turf charcoal led to the design, erection and operation by the Turf Development Board, Ltd., of a plant on the Turraun Bog, from which charcoal suitable for use as a producer fuel was obtained with an output of up to 22 tons a week. Work on town gas resulted in a study of the possibilities of using mixtures of turf and coal, and in modifications in plant which to some extent eased the difficulties being experienced at one of the large gas works. One of the first problems studied was that of mobile gas producers, including the use of an electric filter for the gas; but although such a filter can be constructed, it is not much more efficient, is more expensive and requires much more careful servicing. The drying of turf and the development of a gas specific gravity meter were other investigations in the same field.

Much attention was given to chemicals for the manufacture of matches, including the manufacture both of phosphorus and of potassium chlorate; while a process was also worked out for the manufacture of sulphur by dry distillation from spent oxide. Plant was also developed for the supply of compressed carbon dioxide and ammonia for refrigeration purposes, for aluminium sulphate for water purification and paper manufacture, and for the manufacture of formalin by oxidation of methyl alcohol.

A geophysical survey of mineral deposits of economic importance, and the increase in output to 20 kW. of the existing 1·5 kW. short-wave Marconi transmitter at Moydrum were other tasks undertaken.

The maintenance of such essential medical supplies as anæsthetic ether, glycerol, insulin, and vitamins, and of supplies of yeast and flour for breadmaking, and the manufacture of citric acid by fermentation were other subjects investigated.

Experimental work was also carried out on the production of carbon black by combustion of used lubricating oil, the spectrographic analysis of steel, production of ferro-silicon, electro-deposition of ductile pure iron, carburizing steel for knife-blades, refractory bricks, carbon electrodes, replacements for storage batteries, the recovery of zinc from used primary cells and the alkali treatment of Clare phosphate to give a satisfactory fertilizer. A process was developed for a photo-engraving glue from fish-skins. Work was done on acetone, and processes for ethyl acetate from 80 per cent acetic acid, for agar-agar from seaweed, for an insecticide by extraction of offal tobacco, and a substitute for cutch as a preservative for fishing nets, were also worked out by the Bureau. A modified method for the determination of fat in milk was devised. Advice was given on the use of substitutes for imported wool oil, and for economy and efficiency in the use of lubricating oils.

FORTHCOMING EVENTS

Tuesday, March 11

Zoological Society of London (at Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Royal Anthropological Institute (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. D. Brunt, F.R.S.: "Some Problems of Climate and Man".

Illuminating Engineering Society (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. J. Ivon Graham: "Lighting in Coal Mines".

Sheffield Metallurgical Association (at 198 West Street, Sheffield), at 6.30 p.m.—Dr. Thos. B. Crow and Mr. J. F. Hinsley: "Some Anomalies and Refinements in Diamond Pyramid Hardness Testing of Heavily Cold-Rolled Strip".

Institution of Structural Engineers, Lancashire and Cheshire Branch (at the College of Technology, Manchester), at 7 p.m.—Mr. W. L. MacIvor and Mr. S. R. Reisser: "Practical and Theoretical Approach to Correct Design for Welding".

Wednesday, March 12

Manchester Statistical Society (at the Reform Club, King Street, Manchester), at 5 p.m.—Mr. J. A. Petch: "The Trend of Joint Matriculation Board's Examinations".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C:2), at 5 p.m.—Mr. Reco Capey: "Economic Reconstruction, 5, Craftsmanship".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. A. Van Weelden: "Modern Developments in Geophysical Prospecting".

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. R. N. Berry: "Economics of High-Voltage Transmission by Underground Cables".

Society of Chemical Industry, Microbiological Panel of the Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. B. M. Brown: "The Biological Stability of Beer"; Prof. B. T. P. Barker and Dr. V. L. S. Charley: "The Biological Stability of Cider, Fruit Juices and Soft Drinks".

Chemical Society (joint meeting with the Local Sections of the Royal Institute of Chemistry, the Society of Chemical Industry and the British Association of Chemists, at the Nicholson Lecture Theatre, New Organic Chemistry Department, The University, Dansie Street, Liverpool), at 7 p.m.—Demonstration of Scientific Apparatus.

Society of Dyers and Colourists, Northern Ireland Section (at the Queen's Hotel, Belfast), at 7.30 p.m.—Mr. J. G. Grundy: "The Application and Fastness Properties of Dyes on Nylon".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Outlook in the History of Science" (to be opened by Prof. V. Gordon Childe, Mr. A. R. Halle, Mr. J. G. Crowther and Mr. Philip George).

Thursday, March 13

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. E. W. Taylor: "The Control of Amplitude in Phase Contrast Microscopy"; Mr. J. F. P. Deller, Mr. A. D. O'Connor and Mr. A. Sorsby: "X-Ray Measurement of the Diameters of the Eye".

Illuminating Engineering Society, Manchester Centre (joint meeting with the Electrical Association for Women, at the College of Technology, Manchester), at 6 p.m.—Mr. T. O. Freeth: "Lighting the Home".

Institute of Welding, Sheffield and District Branch (at the Royal Victoria Station Hotel, Sheffield), at 6.30 p.m.—Mr. H. E. Lardge: "Welding in the Development of Jet Propulsion Engines".

Chemical Society (joint meeting with the Local Section of the Royal Institute of Chemistry, in the Chemistry Department, The University, Manchester), at 7 p.m.—Scientific Papers.

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Mr. William C. Peck: "Recent Developments in Pharmaceutical Apparatus".

Society of Dyers and Colourists, West Riding Section (at the Great Northern Victoria Hotel, Bradford), at 7.15 p.m.—Dr. H. P. Staudinger: "Polymer Chemistry".

Chemical Society (joint meeting with the Local Sections of the Royal Institute of Chemistry and the Society of Chemical Industry, at the North British Station Hotel, Edinburgh), at 7.30 p.m.—Prof. A. C. Chibnall, F.R.S.: "The Composition and Structure of Proteins".

Friday, March 14

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 1 p.m.—Mr. L. J. Clarke: "Some Recent Trends in Ribbon Manufacture".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Chemical Society (at King's College, Newcastle-on-Tyne), at 5 p.m.—Dr. H. Bassett: "Some Pages from the Chemistry of Aluminium" (Bedson Club Lecture).

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. A. J. R. Lysholm: "A Contribution to the Solution of the Gas Turbine Problem".

Oil and Colour Chemists' Association, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Dr. E. H. Farmer: "The 'Isomerisation' of Oils—Thermal and Oxidative Changes Involved Therein".

Institute of Physics, Manchester and District Branch (joint meeting with the Industrial Radiology Group, in the New Physics Theatre, The University, Manchester), at 7 p.m.—Dr. L. H. Gray: "The Physical Properties of Very High Voltage X-Rays and Electrons and their Medical Interest".

Chemical Society (in the Chemistry Lecture Theatre, The University, Glasgow), at 7.15 p.m.—Prof. A. C. Chibnall, F.R.S.: "The Composition and Structure of Proteins".

Institute of Metals, Sheffield Section (in the Mining Lecture Theatre, The University, St. George's Square, Sheffield), at 7.30 p.m.—Prof. H. W. Swift: The "Mechanism of Sheet-Metal Drawing".

Saturday, March 15

Biochemical Society (at Guy's Hospital Medical School, London, S.E.1), at 2.30 p.m.—Annual General Meeting, and Scientific Papers.

School Nature Study Union (at the City Literary Institute, Stukeley Street, Drury Lane, London, W.C.2), at 2.30 p.m.—41st Annual Conference; at 3 p.m.—Sir Clive Forster-Cooper, F.R.S.: "Adaptation to Environment".

Institute of Physics, Electronics Group (joint meeting with the Midland Branch of the Institute of Physics, in the University, Edmund Street, Birmingham), at 2.30 p.m.—Prof. P. B. Moon: "The Acceleration of Electrons and Ions to Energies of the Order of 10^8 e.v.".

Monday, March 17

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Dr. J. A. V. Butler: "Enzymes" (Cantor Lectures, 2).

Sheffield Society of Engineers and Metallurgists (at the Royal Victoria Station Hotel, Sheffield), at 6.15 p.m.—Dr. J. Sinclair: "The Underground Mechanization of Coal Mines".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lectureship in Geography—The Registrar, The University, Reading (March 17).

Lecturer in the Department of Geography—The Secretary, The University, Aberdeen (March 20).

Assistant Lecturer in the Department of Geography—The Registrar, The University, Sheffield (March 21).

Senior Principal Scientific Officer in the Directorate of Instrument Research and Development of the Ministry of Supply—The Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1816 (March 21).

Chief Fuel Engineer—The Director of Establishments, Ministry of Fuel and Power, 7 Millbank, London, S.W.1, marked 'Chief Fuel Engineer' (March 21).

Training Officer—The Executive Officer, Kent War Agricultural Executive Committee, Mote House, Maidstone (March 22).

Chair of Inorganic and Physical Chemistry at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (March 22).

Senior Civil Engineering Assistant—The Water Engineer, 55 Dale Street, Liverpool (March 24).

Co-ordinator of Research and Principal at the Punjab Agricultural College, Lyallpur—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (March 28).

Principal of the School of Physiotherapy and Head of the Physiotherapy Department—The House Governor, Royal Victoria Infirmary, Newcastle-upon-Tyne (March 31).

Professional Officers for Rhodesia Meteorological Service—The Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (March 31).

Technical Development Officer—Establishment Branch (Room 266), Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1 (March 31).

Lecturer (woman) in the Department of Education (graduate in Biology, Chemistry or Physics)—The Registrar, University College, Hull (April 14).

Lecturer in Helminthology—The Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1 (April 15).

Lecturer in Physiology—The Secretary, Queen's University, Belfast (May 1).

Lecturer in Biochemistry for Department of Dental Surgery—The Registrar, The University, Liverpool (May 15).

Professorship in the Department of Chemistry—The Registrar, Dacca University, P.O. Ramna, Dacca (East Bengal). India (May 31).

Director of the South African Paint Research Association—South African Scientific Liaison Officer, 39 Princes Gate, Exhibition Road, London, S.W.7.

Assistant Biochemist preferably with experience of hospital biochemistry and hæmatology—The Medical Superintendent, Dudley Road Hospital, Birmingham 18.

Lecturer in Genetics at Auckland University College, New Zealand—The Secretary, Universities Bureau of the British Empire, 24 Gordon Square, London, W.C.1.

Senior Lecturer in Mathematics at Auckland University College, New Zealand—The Secretary, Universities Bureau of the British Empire, 24 Gordon Square, London, W.C:1.

Director of Research—The Physician Superintendent, Runwell Hospital for Nervous and Mental Disorders, Wickford, Essex.

Senior Transmission Engineer for Hydro-Electric Scheme, Ceylon—The Director of Recruitment (Colonial Service), 15 Victoria Street, London, S.W.1.

Senior Assistant Physicist to the Birmingham National Radiotherapy Centre—The Secretary, Birmingham United Hospital, The Queen Elizabeth Hospital, Birmingham 15.

INCENTIVES IN INDUSTRY

THE volume in which Dr. Elton Mayo discusses some of the social implications of scientific and technical advance which have been emphasized by the 'clinical studies' of the Department of Industrial Research of the Harvard Graduate School of Business Administration has reached Great Britain at an opportune time*. Already the necessity of finding new and adequate incentives, in conditions in which man-power and woman-power fall far short of demand and in which increase of productivity is urgent and imperative, has compelled the Government as well as both sides of industry to look closely at problems which have been neglected too long. Simultaneously, the outbreak of a succession of unofficial strikes points to the need for an overhaul of the structure and functions of the trade unions, so as to ensure closer contact between their officials and the rank and file of their membership, as well as a more effective contribution to the welfare of society. The importance of the last point is further stressed by the extent to which the nationalization of industry is changing the broad aspect of relations between employees and employers and the State, and making the strike weapon both archaic and an anti-social sectional weapon endangering the whole fabric of democracy.

Prof. Mayo's main theme is the importance of the group and of methods of understanding not merely the behaviour of individuals but also groups, whether formally organised and recognized by management, or self-constituted informal organisations ; and his book brings to the forefront the problem of securing group collaboration in the essential activities of industry. In doing this, he lays bare even more fundamental issues than Dubreuil did in his study of the autonomous group, for Prof. Mayo is alive to the wider social implications of the impact of applied science ; and in spite of some assumptions in the economic sphere, due partly to failure to define his terms, which the economist may find irritating, he has given us a book that should assist the creative thought demanded in the present situation He recognizes by implication that industry alone cannot achieve full success : there is a political aspect and an indispensable Government contribution, which he appears to contemplate discussing in a third volume. Meanwhile, he has made a valuable contribution to the educational work to be done both within industry and in the universities and technical colleges, as well as to the study of management problems themselves. His book has claims on the attention of all those concerned with the preservation of a free society, the conditions of which he delineates as three-fold : first, a sufficiently general standard of technical skill and literacy ; secondly, the absence of extreme differences in the material standards of living of its various social groups ; and thirdly, the elimination of internal group hostilities and hatreds.

---

* The Social Problems of an Industrial Civilization. By Prof. Elton Mayo. Pp. xvii+150. (Boston, Mass. : Graduate School of Business Administration, Harvard University, 1945.) 2.50 dollars.

It needs no more than the most superficial glance at the events of the past year to realize that although the whole trend of policy in Great Britain during the past decade has been towards the levelling of the differences in material standards of living, the second and third conditions are as yet by no means fulfilled. Behind the recent strikes lies a question of the quality of citizenship which is only partly a trade union matter; and which is of increasing importance as more and more industry passes within the orbit, if not directly of the State itself, at least indirectly in the public corporations. Moreover, the declining level of general intelligence which Sir Cyril Burt's recent study has indicated makes it imperative that more attention should be given to this factor of education, and there is as yet little evidence from the men returning to civil life from the Services that the educational work in the Forces has proved effective in raising the level of understanding of the meaning and responsibilities of citizenship.

Increasingly we are coming to realize the searching demands that a democratic society makes of its citizens; and the supreme reason for seeking urgently and imperatively to eliminate the divisions due to group hostilities is that they present a fatal obstacle to effective participation and co-operation both within industry and also at the international level. Effective co-operation is the condition of industrial efficiency and higher productivity in Britain, just as much as it is the condition for the survival of civilization in the international sphere. Civilization, as Prof. Mayo points out, can destroy itself if it fails to understand intelligently and to control the aids and deterrents to co-operation, and his recurrent theme is that if our social skills had advanced step by step with our technical skills, there would not have been a second world war.

In the first of the two essays, "Science and Society", Prof. Mayo urges that collaboration in an industrial society, whether in a political or an industrial unit, cannot be left to chance; but hitherto all our administrative methods have been aimed at securing satisfaction of material and economic needs, and not at the equally important problem of maintaining spontaneous co-operation. Absenteeism, the turnover of labour, and unofficial strikes testify to our ignorance of how to ensure the spontaneity of co-operation, the team-work that was the characteristic of so many outstanding achievements in the scientific and technical field during the War. Moreover, we have passed beyond the stage of human organisation in which effective communication and collaboration were secured by established routines of relationship. As Lewis Mumford has pointed out, we are living in an age when we can no longer assume that the technical processes of manufacture will exist unchanged for long in any type of work.

That, of course, is one reason why conditions of full employment imply greater mobility of the workers and why it is imperative for the trade unions to re-examine their outlook and practice. Adaptability and not restriction is the condition of social security; and the very instability of techniques makes a fuller stability in companionship imperative. We have to acquire new social skills that will be effective in the specific situations, and although this must be in the main a task of management and a major responsibility of all institutions concerned with the training of those destined to occupy positions of leadership, it is a task in which every worker is also concerned. Prof. Mayo undoubtedly puts his finger on the weak spot in suggesting that the outstanding defect of civilization is the incapacity of groups to communicate effectively and intimately with each other.

The defect lies at the root of most of the acute issues developing between managements and workers, and indeed between Government and people, as it often does of the failure of men of science to secure proper appreciation by the administrator of the scientific factors in a situation. Scientific men at least are coming to appreciate more fully that, as Prof. Mayo observes, the development of usable skill must be accompanied by the acceptance of responsibility of one kind or another. The widespread manifestation of a sense of social responsibility in relation to the development of atomic energy which has characterized scientific workers in the United States and in Great Britain during the last eighteen months is possibly one of the most hopeful and healthy signs of recovery on that side.

Prof. Mayo is less happy in his second essay, in which he discusses what he terms the 'rabble hypothesis' and its corollary, the State absolute. He emphasizes in conclusion that the active development of social skill and insight is required to make the forms of democracy come alive, and he returns to this theme in the concluding chapter of the book. He argues that the only way of dealing with the industrial or the international situation is by, first, the patient, pedestrian development of first-hand knowledge; secondly, the development of skill in handling the facts through intimate acquaintance; and thirdly, the clear statement of the logical implications of the effective skill.

Modern civilization, Prof. Mayo urges, is greatly in need of a new type of administrator, who can, metaphorically speaking, stand outside the situation he is studying; and throughout the book his main emphasis lies on the organisation of co-operation, because it is so largely ignored in the universities, in industry and in political statements. Knowledge of the relevant technical skills and of the systematic ordering of operations is indeed essential; but it is to the need for close observation, for the ability to communicate and to listen, and to train students in the study of social situations that he is primarily concerned to direct attention, emphasizing that first-class technical training alone is insufficient in a modern and mechanical age.

The capacity of the individual and of the group to become adapted to new circumstances and to new relations with other people has been made a vital necessity in our adaptive society by the great pace of modern technical and industrial development; and the most disturbing feature of the present situation is that so few professional organisations, whether trade unions or not, have shown any real appreciation of the fact. It should indeed be a prime purpose of the production committees and works councils to increase this adaptability or flexibility: information is an important means to that end. The attitude indicated in what is generally known as the 'closed shop' policy is most sinister in that it threatens the existence of the very groups which might provide stability; and in so far as the formation of very large trade unions is encouraged for reasons of ease of negotiation, it is vital that within the large union something corresponding to personnel management or public relations should be developed, to ensure real contact and understanding between the national and regional leaders and the local groups and rank and file of the membership.

There follows from this the necessity for developing intensively industrial relations in their widest sense, by either the formation of workers' councils and committees, or the constant provision of full information regarding the purposes of industrial policy to the workers individually and to their organised groups. There is room for effort from both the trade union and the employers' side for initiative in this field, in order to dispel the legacy of distrust which is one obstacle to higher productivity; and the industrial psychologist may well have a vital contribution to make in raising the whole standard of what for want of a better term is known as personnel management. Included in this is the training of leaders at the lower levels of responsibility—the foreman and charge-hand on the part of industry, the shop-steward on the part of the trade unions. If management and trade unions could work out jointly a policy of selecting and training men for such positions in the best interests of industry, from the point of view of the nation, we should have taken a big step towards securing co-operation at the vital level of production and at the same time have assisted in the formation of those very groups which provide the individual with the satisfaction and security he seeks, while linking them to the service of society as a whole.

A wide field exists for further research. We need to know more about the best methods for securing adequate representation from small groups of employees in sections or departments, and for discussions of company policies or procedures prior to their introduction, and information on production, sales, finance, etc. The whole problem of incentives in industry demands a searching re-examination, and new methods are required for bringing up and discussing such matters as 'waiting time', absenteeism, raw material shortages, labour shortages, production targets and the like.

The great value of Prof. Mayo's book is the vivid way in which it indicates the practical possibilities of group co-operation and relates them to the larger problem of the renewal of democracy not merely in industry but also in the world as a whole. It is true that, however urgently they are explored, they cannot bring their full effect to the solution of the immediate problem of increasing productivity, although the very initiation of such investigations might have a profound psychological effect. A similar comment applies to remarks of the Chief Inspector of Factories in his last annual report regarding the need for a general cleansing and refit to bring British factories back to their pre-war standard, and the introduction of more light and colour to brighten them up and take them a step beyond; all this clearly depends on factors outside the control of industry itself. Shortages of labour, materials and plant—not to mention difficulties in the way of obtaining the necessary permits—undoubtedly hinder or prevent the use of such means of increasing industrial efficiency; nevertheless, it is important to recognize and acknowledge their significance in promoting better relations in industry.

Something more could certainly be done even now to raise the standards of industry generally and thereby the standard of productivity. For such improvements, in the furthering of which the man of science will often have an essential part to play, help to persuade men and women that production is indeed a social task, and by raising what, for want of a better word, may be termed the morale of workers again, assist that greater interest and effort on which higher productivity depend. Here again is a field in which the scientific worker has much to contribute. The whole question of incentives offers vast scope for investigation by the psychologist, and other men of science may indeed be able to offer contributions. For success in this matter management must be bold and imaginative, and ready to experiment. Some of the essential scientific spirit must be given free play, linked to that respect for human personality which characterizes the 'clinical studies' described by Prof. Mayo; and this must pervade the trade unions as well as management. For this reason it is important that the man of science should be associated not only with the management of industry but also with the trade unions.

There is much that is suggestive in Prof. Mayo's work, and the ideas and methods he outlines do indeed point the way forward to a closer integration of industry with the society it exists to serve, and to a fuller understanding between worker and management. Furthermore, the discussion in the dispassionate spirit of science of the implications in full employment of the forty-hour or five-day week, staggered holidays with pay, pensions and retirement, and the relation of hours of work to age and physical fitness or disability, may assist us to reach new and imaginative solutions which will permit a wiser and more efficient use of man-power and woman-power at all ages, and the greater productivity which is now our imperative need. At the same time, such studies may lead to the release of men and women in industry from some of the excessive strain to which they are likely to be subjected when they first enter industry and, at a later stage, when their working life is drawing to its close.

SCIENTIFIC POLICY FOR THE NEW WORLD

Endless Horizons

By Dr. Vannevar Bush. Pp. ix + 182. (Washington, D.C.: Public Affairs Press, 1946.) 2.50 dollars.

THE concerted effort that linked the men of science of Great Britain during the Second World War was remarkable in the ease of its occurrence, in its achievements, and, contrary to many fears, in the fact that scientific 'planning' was not apparently associated with any evil consequences—except perhaps in so far as we did not plan sufficiently for the continuation of fundamental research. We were particularly fortunate in all this, and we owe a large part of our success to the fact that in the scientific and technical departments of the Service and other Ministries, and even more so in the Department of Scientific and Industrial Research, the Medical Research Council and Agricultural Research Council, we possessed powerful official agencies to act as a kernel for our scientific mobilization.

In this respect British men of science were far better off than their colleagues in the United States. Apart from certain Service establishments, the only counterpart to British official scientific organisation which was available to them when war broke out in Europe was the National Research Council, acting under the auspices of the National Academy of Sciences. The Council was a creation of the First World War; but either its structure was unsuited, or its practical influence on the scientific life of the United States during the inter-war years was insufficiently extensive, for the task of co-ordinating scientific activity on a national scale in an all-out war effort. In 1940 the President of the United States accordingly established a new committee, the National Defense Research Committee (N.D.R.C.), for the purpose of developing new weapons and instruments of war. A year later he founded an Office of Scientific Research and Development (O.S.R.D.), which absorbed the N.D.R.C., and had the function of co-ordinating the efforts of men of science and technical men in a much wider field of the war effort.

Dr. Vannevar Bush, previously head of the engineering section of the Massachusetts Institute of Technology, and at the time president of the Carnegie Institution of Washington, was placed in charge first of the one and then of the other of these two organisations. Their success so impressed Mr. Roosevelt that, towards the conclusion of hostilities, as is now well known, he called on Dr. Bush to submit a practical plan for the consolidation of the scientific gains of the War, both in the sense of making them as widely known as was consistent with military security, and of ensuring their continued extension by discovering, educating and endowing scientific talent in the United States. The O.S.R.D. was wound up not many months ago, and it is some months since open, official discussion of Dr. Bush's reply to the President languished in silence. In the interval two relevant changes have occurred. In the first place, scientific organisation in the United States has returned to its pre-war model, with the very important distinction that the Service Departments appear to have usurped the function of O.S.R.D. as the benefactors of large-scale research projects in the universities. In the second, the British have reacted to much the same type of consideration as exercised Dr. Bush when he was framing his reply to the President's question, by increasing the scale of university education, without making any inroads into university autonomy, and by trying to improve the organisation by which scientific advice makes itself felt in the national sphere at policy-making levels.

In the light of these two events, "Endless Horizons", which was published about a year ago in the United States, makes interesting reading—or re-reading—to-day. It is a collection of Dr. Bush's public utterances, between the years 1933–45, on technical and scientific matters. Its body is his report to the President, coupled with a brief account of the organisation and achievement of the O.S.R.D. Its frame is made up of such diverse, personal materials as his image of the 1930's as seen from a far-distant future when "all the desirable modifications of our natural environment" have been accomplished through some simple mechanical means; his well-known essay on the need for mechanical recording devices which will relieve the individual of much of the effort that still goes into the processes of natural memory and the exercise of formal logic; an essay on the conditions of scientific progress, called "The Teamwork of Technicians"; one on "The Qualities of a Profession"—dealing with the special case of engineers; another on the American tradition of opportunity; a lecture on "The Need for Patent Reforms"; and finally an address on "Science for World Service".

At the time of its appearance, Dr. Bush's report to the President was the subject of a leading article in these columns, and a large number of British men of science will be aware, at least in general, of the achievements of the O.S.R.D. The only new interest of the present volume is therefore a glimpse, even if an indirect one, of Dr. Bush's personal philosophy about the meaning of scientific activity. Coming as it does from the man responsible for the blue-print of America's future scientific organisation—even if at the moment the blue-print remains unrealized—it is an important one. The note is struck in his main report: "Without scientific progress," he told the President, "no amount of achievement in other directions can insure the health, prosperity and security" of the United States as a nation in the modern world; and since scientific progress is therefore of vital interest to Government, science must—in Dr. Bush's own words—be brought to the centre of the stage, and provided with a national policy which will ensure the rapid extension of a process, the utilization of science in the nation's welfare, which has only just begun. None of this message makes strange reading in Britain. What might be unexpected, however, is the predominantly material and social flavour of Dr. Bush's credo. It characterizes not only the reasons he gives for the federal action which he proposes, but those of his essays which are completely unrelated to this question. Dr. Bush, an apostle of science in the most individualist of countries to-day, calls for a national policy for science, and high-level planning for science, in far bolder terms and in a more materialist context than any but a few, if indeed anyone, has used in Britain.

His essays in "Endless Horizons" do not reveal much preoccupation with any abstract or non-applicable science. His 'historical' view of the 1930's, which opens the collection of essays, is a racy account of such inadequate gadgets as electric light, motor-cars, and spectacles. Nor does the implied picture of the distant future in which science will have achieved all the desirable changes in these matters carry any suggestion that they will have been associated with any corresponding evolution in general understanding—beyond the implication which lies in the statement "science of the times [1930's] was disjointed, heterogeneous and very much an opportunist affair". The world, Dr. Bush explains to one of his audiences, "has arrived at an age of cheap complex devices of great reliability; and something is bound to come of it". To the President he wrote that "a nation which depends upon others for its new basic scientific knowledge will be slow in its industrial progress and weak in its competitive position in world trade, regardless of its mechanical skill".

It is thus to a world of individualist enterprise that Dr. Bush makes his appeal for the establishment of a council to control the scientific policy of the United States. He may, of course, be wrong in assuming that advances in science when put to practical use necessarily "mean more jobs, higher wages, shorter hours . . . and higher standards of living"—since these things depend at least as much on socio-economic factors as on scientific progress. But whether the atmosphere be the rich and individualist one of the United States, or the Spartan and socialist one of Great Britain to-day, it seems to be generally recognized that the time has come for the State to play a central part in stimulating scientific progress.

It is equally to the interest of both countries that policy-making for science should not conflict with the peripheral autonomy of universities and research institutes in carrying out their research and educational programmes. Freedom of inquiry is a cherished possession; and, as Dr. Bush shows so clearly, because of the different and sometimes conflicting demands it must satisfy in different fields, national scientific policy is scarcely likely to lend itself to easy formulation. By itself science provides "no panacea for individual, social and economic ills". There is a possibility, to which Dr. Bush does not refer, that the widespread extension of scientific knowledge, and its methods, might achieve more in this respect than the direct exploitation of the material gains of science. Perhaps he deliberately avoided emphasizing this not-so-materialist point of view. History, however, will judge of the value of a national scientific policy by the wisdom of the compromise it effects between the more immediate satisfaction of domestic demands of security and economic and social welfare, and the longer-term necessity to spread the methods and fruits of scientific knowledge as widely and as internationally as possible.

S. Zuckerman

THE LIQUID STATE

Kinetic Theory of Liquids

By J. Frenkel. (International Series of Monographs on Physics.) Pp. xi+488. (Oxford: Clarendon Press; London: Oxford University Press, 1946.) 40*s*. net.

This book does a great service by collecting together much scattered information on a fascinating and rapidly developing subject, contributions to which have appeared in a great many different journals. Discussion of liquids inevitably leads on to such topics as fusion and evaporation, the theory of solutions, the properties of polymers and rubber-like substances, and so on. Certain of these topics are dealt with at considerable length, others rather sketchily, and it is regrettable that no attempt has been made to link up the statistical theory of turbulence with the molecular theory of liquids. As is inevitable in so vast a subject, some of the matter is already out of date, and it is only right to mention that the book was written in Moscow in 1942, and has suffered delay in publication. In spite of these shortcomings, the book fills a very obvious gap, and cannot fail to be of permanent value to a serious student of any of these subjects. In spite of the War, the book is printed on very nice paper, and the high standard of craftsmanship that one instinctively associates with this series of monographs has been well maintained. The references are given in footnotes, which is far more convenient than grouping them at the end of the chapters, but one would welcome a complete bibliography at the end of the book, or else a subject index. Another improvement that could easily be made in a new edition is the addition of a list of symbols.

The reviewer feels bound to take exception to an objectionable feature of the book, which is the very scornful way in which the work of others is criticized. In a rapidly advancing subject it is inevitable that many theoretical deductions will be found to be based on erroneous premises, and a detailed criticism of such theories is of great value, and is, indeed, necessary for progress. In some instances, however, the author appears to think that a few words are enough to annihilate the rival theory, and, in at least one instance (p. 155 footnote), he does not attempt to explain his objections at all. Such an attitude is both unfair to the author of the theory and unhelpful to the reader who is trying to decide between two points of view. The reviewer quite agrees that many of these criticisms are justified, but there are cases where the author has been beguiled into definite errors by this over-hasty attitude. For example, p. 55: "As a matter of actual fact, such transitions have never been observed and cannot correspond to a stable equilibrium between the phases". (The type of transition referred to is a second-order transition as defined by Ehrenfest.) It is very hard to reconcile the first part of this sentence with the observed specific heat curves associated with the onset of superconductivity and with the transition of liquid helium. A definite refutation of the second part has been given by Bridgman[1].

The Lennard-Jones and Devonshire theory of melting is apparently criticized (p. 111) on the ground that the entropy-temperature curves (plotted at constant pressure) show a monotonic increase instead of being S-shaped. The answer to this is simply that the entropy-temperature curve consists of *two distinct* branches, corresponding to the two valleys in the surface depicting free energy as a function of volume and temperature. The process of melting at constant pressure consists of a transition from one branch to the other, and the melting temperature is determined by the usual condition that the Gibbs function must be the same for both phases.

Throughout most of the book, the author treats a liquid as having a structure akin to that of a solid the long-range order of which has been lost. Chapter 1 therefore starts by considering various possible processes by which 'holes' can appear in a crystal, and lattice imperfections can diffuse through it. The length of this chapter seems excessive, as it seems to do little more than establish that the probability of such processes is governed by a factor of the type $e^{-W/kT}$, and to suggest various means of roughly estimating W. Chapter 2 contains a review of some of the theoretical work on order-disorder in alloys and the onset of free rotation in crystals. It is a pity that no mention has been made of the powerful 'quasichemical' method of Fowler and Guggenheim, which enables one to predict, at least approximately, the statistical consequences of very complex physical models which would be very difficult to treat by the older methods, and yet is easy to handle, and is, when applied to simple cases, precisely equivalent to the older theories. The advent of Onsager's work[2] will ultimately necessitate the revision of many of the conclusions of this chapter, particularly those related to the shape of the specific heat curves. It has become clear that the theoretical shape of the specific heat anomaly associated with a co-operative change will be very sensitive to the exact details of the model and to any approximations used in working it out.

Chapter 3 deals mainly with the process of fusion and various criteria for the stability of a crystal lattice, but it also contains an extremely able presentation and criticism of the work of Kirkwood and Prins on the 'structure function' of liquids, the assumptions and approximations that are made in this rather difficult but very important work being carefully pointed out. The discussion of the stability of a line of atoms under specified interatomic and external forces is also of great merit in exhibiting the relationships between the form of the interatomic interaction, the thermal expansion, and of the effect of heating or external forces on the stability of the lattice. An interesting result for the linear model is that it cannot be made stable against both longitudinal and transverse displacements, but this is no longer true for a three-dimensional model. The results are applied to give a rough theory of fusion, but no attempt is made to derive quantitative results.

Chapter 4 deals with the author's theory of viscosity of a liquid, which may be regarded as a generalization of the ordinary theory of elasticity of a solid, the response of a liquid to an external shear being specified by the rigidity modulus, together with a relaxation time specifying the mean life of a molecule in one equilibrium position. Analogous considerations are applied to the compressibility modulus and thus lead to the concept of 'volume viscosity', which is attributed to a relaxation time associated with structural changes in the liquid. From a consideration of the experimental data on absorption of supersonics in liquids it is concluded that the volume viscosity of liquids is large compared with the ordinary viscosity. The alternative explanation, analogous to the well-known theory of dispersion and absorption of sound in gases, is examined and rejected, as, to account for the observed absorption, it would require dispersion at frequencies of the order of 10^8 per sec., which is not observed. The reviewer agrees with this conclusion; but the value of this section would have been much enhanced by a critical summary of the experimental material. Another very interesting section in this chapter deals with the diffusion of gases and solids through liquids, and a reasonable explanation is given of the rather puzzling fact that the diffusion coefficients of different substances are of the same order of magnitude for a given liquid.

Chapter 5 is concerned mainly with the orientation of molecules in liquids, and the work of Debye, Onsager, Kirkwood and others on the problem of the behaviour of polar liquids in an electric field is expounded with great clarity; but here, again, very little experimental material is introduced, and the reader is consequently left in considerable doubt on how much the theories are claimed to explain.

Chapter 6 is mainly a phenomenological discussion of the properties of thin films of liquid and certain allied phenomena. Chapter 7 deals with the fascinating problem of the way in which phase-transitions actually occur. Two of the factors which cause actual transitions to depart from the ideal reversible transition are time-lag in the rearrangement of the molecules, which can lead to a liquid solidifying into the glass-like amorphous state instead of crystallizing, and surface tension. If the surface tension is positive, as it is between a liquid and its vapour, it is possible to superheat the liquid or supercool the vapour far beyond the equilibrium temperature before the transition takes place, because of the difficulty of forming a 'nucleus' of the more stable phase. If, however, the surface tension were negative, the formation of a nucleus would be facilitated, and metastable states would not be possible at all, even under ideal experimental conditions. In fact, no liquid with such a property is known, but it is possible to explain an apparent anomaly connected with fusion. The difference in surface-energies of solid and liquid is always small, but in some cases it is possible to supercool a liquid, and even to superheat a solid, provided that the latter is heated *internally*. Attempts to superheat a solid by heating its free surface invariably fail, however, and it seems that the effect of the free surface is always to lower the energy required to form a nucleus of the liquid phase, and this is what would be expected theoretically.

Chapter 8 deals with the theory of solutions, including those of high polymers, and the properties of rubber-like substances. The author's interests plainly lie in the two latter directions, and the treatment of 'classical' solutions is extremely sketchy, no attempt being made, for example, to expound or discuss the Debye–Hückel theory. The account of the present state of the theory of the behaviour of long-chain molecules seems rather incomplete; for example, no attempt is made to examine the error caused by treating a chain 50–100 'links' long as 'infinite'. Here, again, the lack of a survey of the experimental work on long-chain molecules is acutely felt.

In subjects of this sort, which are in their infancy, the comparison of theory with experiment leads to less clear-cut conclusions than it does in more developed fields of physics. Any theory will, in this field, certainly involve several adjustable constants, and it may well be possible to fit even a wrong theory to most of the facts; but all facts that *cannot* be fitted should certainly be recorded. The fact that this has often not been done detracts somewhat from the merits of a very readable presentation of some far from simple theoretical work. The author never once seems to be carried away by the mathematics, but keeps the essential physical ideas before his reader throughout. H. N. V. TEMPERLEY

THE BODY'S CHEMICAL MECHANISMS OF DEFENCE*

By Dr. C. R. HARINGTON, F.R.S.

THE defence of the body against the poisonous action of compounds of simple chemical constitution is effected by a variety of chemical reactions. The toxic compound may be oxidized to a non-poisonous product, or to one for which a rapid means of elimination exists. Non-oxidative processes of elimination usually involve conjugation with a normal constituent of the body to give a substance which is relatively non-toxic and is readily excreted. The body shows considerable versatility in the means which it adopts for conjugation of toxic compounds. Examples are the formation of ethereal sulphates from phenols, of glucuronides from phenols and aromatic acids, the combination of organic acids with amino-acids to form products of the hippuric acid type, and the detoxication of halogenated benzenes by linking with acetylcysteine to form mercapturic acids. A certain species-specificity is shown in detoxication by conjugation with amino-acids; thus benzoic acid is combined with glycine to give hippuric acid in all mammalian species so far examined, but in birds it is coupled with ornithine to give ornithuric acid; similarly, phenylacetic acid is detoxicated by conjugation with glycine in man and the chimpanzee, with ornithine in birds and with glutamine in the dog, rabbit, cat and monkey.

The reactions by which detoxications take place occur for the most part in the liver, and their quantitative examination can therefore be made the basis of assessment of hepatic efficiency. This is illustrated by the use of the measurement of hippuric acid excretion following a standard dose of benzoic acid as a liver function test.

Chronic poisoning with a compound which is detoxicated by conjugation may lead to deleterious effects even though the actual conjugating mechanism remains unimpaired. This may happen when the substance utilized by the body for the detoxicating reaction is one which is an essential constituent of the tissues and is at the same time limited in supply. In the case of the mercapturic acid conjugation, the constituent supplied by the body is acetylcysteine, which is a derivative of the essential amino-acid cystine. Since the amount of cystine in the diet is limited, prolonged administration of a compound such as bromobenzene to a growing animal may show its effects by limiting growth, owing to the drain imposed on the supplies of available cystine, in the absence of any signs of direct poisoning by the bromobenzene itself.

Apart from the species-specific utilization of different amino-acids for the detoxication of organic acids, the processes by which the body deals with simple chemical poisons are for the most part group reactions; so that it is possible, from a knowledge of the chemical constitution of a poisonous substance, to predict the probable route of its detoxication.

In protecting itself against invasion by pathogenic bacteria or against the effects of toxins produced by such bacteria, the body adopts entirely different methods.

An attack of an infectious disease frequently produces a condition of life-long immunity to the same illness; immunity of long duration can also be achieved in many cases by vaccination with the killed causative organism, or with products obtained from this organism. In addition to the active state of immunity thus conferred by natural infection or by vaccination, a temporary passive state of immunity can be produced by treatment with the blood serum of an animal which has been infected with the disease or has been vaccinated against it. These facts indicate that the process of immunization calls forth a response in the body which confers upon it powers of defence against subsequent invasions by the same organism; and the phenomenon of passive immunization suggests strongly that these powers are associated with a definite change in the blood of the immune individual.

The fact that the blood is actually altered as the result of immunization can be demonstrated by various reactions in the test-tube. Thus a suspension of infective bacteria, which remains quite stable when mixed with normal blood serum, may be agglutinated when mixed with the serum of an individual immune to the disease caused by the particular bacterium concerned. When the bacterium produces a soluble toxic substance, this will be precipitated and neutralized by the immune serum but not by normal serum. In other instances the bacterium may actually be dissolved by the immune serum. It thus becomes possible to envisage the defence reaction of the body against infection in terms of physical or chemical interaction between a substance newly formed in the blood, which may be designated 'antibody', and the eliciting agent (bacterium or bacterial product), conveniently called 'antigen'.

Although the presence of antibodies in the blood can be demonstrated by a variety of test-tube reactions, there is no real reason to suppose that they are of correspondingly different types. The general features of the antigen-antibody reaction are those of an ordinary colloid chemical reaction (including the zoning phenomenon), and it is more probable that the different physical manifestations of the reaction reflect differences in the physical state of the antigens. All available evidence supports the view that antibodies are specifically altered forms of a definite fraction of the serum globulins.

Antigenic power is not confined to pathogenic bacteria and their products, but extends generally to all proteins which are foreign to the body. Such foreign protein does not act antigenically when taken in the food, because it is broken down by digestion; if, however, it is introduced directly into the deeper tissues of the body it elicits a response similar to that produced by bacteria. There is a considerable variation in the antigenic power of different proteins, the highest activity being found among the proteins of the blood and actively metabolizing tissues, and the least among the highly specialized hormonal proteins.

The power of foreign proteins to act as antigens has been used extensively for the study of the specificity of the antigen-antibody reaction. The method adopted has been to induce known alterations in the protein molecule by the use of reagents which attack the functional groups of the latter. Examples are the use of acid chlorides and azides which react with amino- and hydroxyl-groups, treatment with halogens which enter the benzene ring of tyrosine, and coupling with diazonium salts which again react with tyrosine; the latter method particularly has made it possible to introduce a large variety of new groups into proteins. Study of artificial protein derivatives produced in this way has shown that a new antigenic specificity is conferred by the group introduced, which frequently masks the original specificity almost completely. For example, if an iodinated protein is used as antigen, the antiserum against it will fail to react with the original protein but will react with iodinated proteins in general. A very high degree of specificity is attached to the new group introduced, minor chemical differences such as that between α- and β-glucosides being detectable in the antigen-antibody reaction *in vitro*. If the new group has physiological activity, this may be neutralized by the antiserum in the same way as a toxin is neutralized by an antitoxin.

---

* Abstract of the Friday Evening Discourse at the Royal Institution on December 13.

The precipitation of an artificially altered protein by its specific antiserum is inhibited if the antiserum is first treated with excess of the simple chemical compound attached to the protein in the preparation of the antigen. The inhibition occurs because the specific combining sites on the antibody are occupied by the simple compound, and antigen-antibody combination is thus prevented. This inhibition reaction therefore gives reality to the conception that the new groups introduced into artificial protein antigens form actual points of attachment with the antibody, and justifies the designation of such groups as 'haptenes'.

It is now known that among bacteria a situation exists which is similar to that described for the artificially conjugated antigens. Bacteria in general contain complex polysaccharide groups, and it is these groups which confer antigenic specificity ; they are in fact bacterial haptenes, and it is they which determine the structure of the specific antibodies formed against bacteria.

The defence mechanism of the body against bacterial invasion thus consists in the development of antibodies, by virtue of the antigenic power of bacteria due to their content of foreign protein ; the nature of the antibodies is determined by the structure of the bacterial antigen, and in particular by the carbohydrate group of the latter, so that they acquire the specific power of entering into colloidal combination with antigen which they may eventually encounter. The results of the combination, as seen in the test-tube, may be manifold ; but with whatever *in vitro* reaction they are associated, their object, so far as the body is concerned, is protection against the harmful effects of the bacterium or of its products.

The very readiness of the body to react to the introduction of foreign protein, which is essential in the development of defence against bacterial invasion, can itself be an embarrassment. The ordinary defence mechanism which has been described is developed naturally against a continuously increasing amount of antigen, as when invading bacteria undergo multiplication or produce increasing amounts of toxin. Similarly, in artificial immunization, the antigen is usually applied in frequent and increasing doses. If a single small dose of antigenic material is injected into an animal and the latter is left for ten or more days, it passes into a hypersensitive state in which acute toxic effects are produced by a second small dose of the same antigen. The phenomenon is seen in its extreme form in the guinea pig, in which the second dose results in acute bronchial spasm, frequently leading to death of the animal. Accidental sensitization often occurs in human beings, who are, however, much less reactive than the guinea pig ; the analogue of the fatal bronchial spasm (anaphylactic shock) in the latter is the attack of asthma in the individual who has become sensitive to a protein such as that of the dandruff of horse-hair whenever he is exposed to the original sensitizing agent. In general, phenomena of this type are described as allergic, to indicate the altered reaction by which the body responds to contact with a previously harmless substance as if it were a powerful poison ; in addition to asthma, they include the catarrh of hay fever, the nettle rash associated with sensitivity to certain foods, and the dermatitis which results from superficial contact with sensitizing agents and which is perhaps the commonest manifestation of allergy in man.

The nature of many of the substances which induce allergy and the specificity with which they exercise their effects indicate that the allergic phenomenon is essentially an antigen–antibody reaction. On the other hand, it is usually impossible to detect antibodies to the sensitizing agent in the blood of an allergic patient, so that the antibodies must be fixed to certain tissues (such as the bronchial musculature or the skin) which respond by abnormal reaction to contact with antigen.

Allergic phenomena, and particularly dermatitis, are frequently produced by simple chemical compounds unrelated to protein. The explanation of this is that such compounds are either themselves able to react with proteins or are converted in the body into a reactive form. They may thus be designated pro-antigens, since although they are themselves not antigenic they will, when they gain access to the body, react with tissue proteins and so alter these as to turn them into antigens. Pro-antigenic compounds of this type are met with not infrequently ; examples are *p*-phenylenediamine, which is responsible for dermatitis from furs, and the sensitizing principles of *Primula* species and poison ivy (*Rhus Toxicodendron*) which make it impossible for some individuals to touch these plants without acute skin irritation. They occur still more commonly in chemical industry, where they may be a source of serious inconvenience.

In general, allergy may be regarded as being at the same time an illustration of the defensive reactivity of the body against foreign protein and a deviation of the defence mechanism which is actually deleterious.

COUMARIN AS A SELECTIVE PHYTOCIDAL AGENT

By Dr. L. J. AUDUS
AND
Dr. J. H. QUASTEL, F.R.S.
Agricultural Research Council, Unit of Soil Metabolism,
University College, Cardiff

THE recent discovery[1,2] that synthetic plant-growth substances such as 2 : 4-dichlorophenoxyacetic acid have selective phytocidal actions in very low concentrations has opened up a new field of investigation into their mechanisms of action. The search for new molecules with similar properties has been intensified. The fact that unsaturated lactone groupings are frequent features of naturally occurring substances having inhibitive effects on cell-growth[3,4,5] revives interest in the phytocidal activity of the common plant metabolite, coumarin. This substance was, apparently, first shown by Klebs[6] to be toxic to Algæ, and later by Schreiner, Reed and Skinner[7] to have inhibitive effects on the growth of wheat. Cameron[8], in a discussion on soil fertility, referred to the fact that both coumarin and daphnetin prevented the development of wheat, and Sigmund[9] noted the effects of daphnetin and æsculetin on seed germination. In 1934, Köckemann[10] gave the term 'blastocholine' to material of unknown structure, present in ripe fruits, which suppressed germination of cress seeds. Since then it has been shown[11,12,13] that a number of unsaturated lactones, including coumarin, parasorbic acid and β-angelicalactone have blastocholine effects, suppressing germination of seeds at concentrations such as 100 parts per million. The concentrations at which the lactones are effective have been considered to be much higher than those which bring about comparable effects with 2 : 4-dichlorophenoxyacetic acid.

Selective Phytocidal Action of Coumarin

In view of these facts, we decided to set up experiments, with a number of plant species, to investigate the possible activity of coumarin as a selective phytocidal agent. Comparisons were made of the effects of coumarin with those of 2 : 4-dichlorophenoxyacetic acid on the same species of plant. A water culture technique was employed. 15 ml. portions of standard water culture solution (the same as that of Nutman, Thornton and Quastel[1] was used, with the omission of potassium nitrate) containing various dilutions of the phytocidal agent were placed in $\frac{5}{8}$-in. test-tubes, and 'thimbles' of glass wool were then pushed down the tubes until they just touched the surface of the medium and became soaked by it by capillary action. These 'thimbles' stayed firmly in place in the tubes during all subsequent handling, and were found to be very efficient supports for the seeds. They ensured optimum aeration and constant contact with the medium, and in addition, the radicles could easily grow through the fine sieve-like meshes into the culture medium itself. The tubes were plugged and then autoclaved, and all seeds were surface-sterilized with 80 per cent alcohol and dilute mercuric chloride[1] before sowing in the tubes. Samples varied in number from 30 to 100 seeds per tube, depending on the species under consideration. The need for thorough sterilization of culture media and surface sterilization of the seeds had been made obvious to us in preliminary experiments with indolylacetic acid. This substance, which shows high phytocidal activity in sterile media[1] at a concentration of one part in ten million, loses its activity in unsterilized media, owing to vigorous bacterial attack. Precautions concerning sterility were therefore taken in testing the phytocidal activities of all plant-growth substances used in small concentrations.

Seeds were allowed to germinate for 1–2 days in the dark and then grown in normal daylight at 20° C. When the roots of the 'control' seedlings had reached a suitable length (generally after about 7–10 days growth) the experiment was stopped. The roots of all sets of seedlings of a series were cut off with a sharp scalpel, dried rapidly on blotting paper, and were then weighed rapidly and accurately to the nearest 0·1 mgm. This final weight of root has been taken as the measure of growth for estimation of the phytocidal action of the substances concerned. It has been shown, for 2 : 4-dichlorophenoxyacetic acid and other similar agents, that root-growth is the most sensitive and consistent measure of their effects. In addition, the percentage germination was also determined in each case.

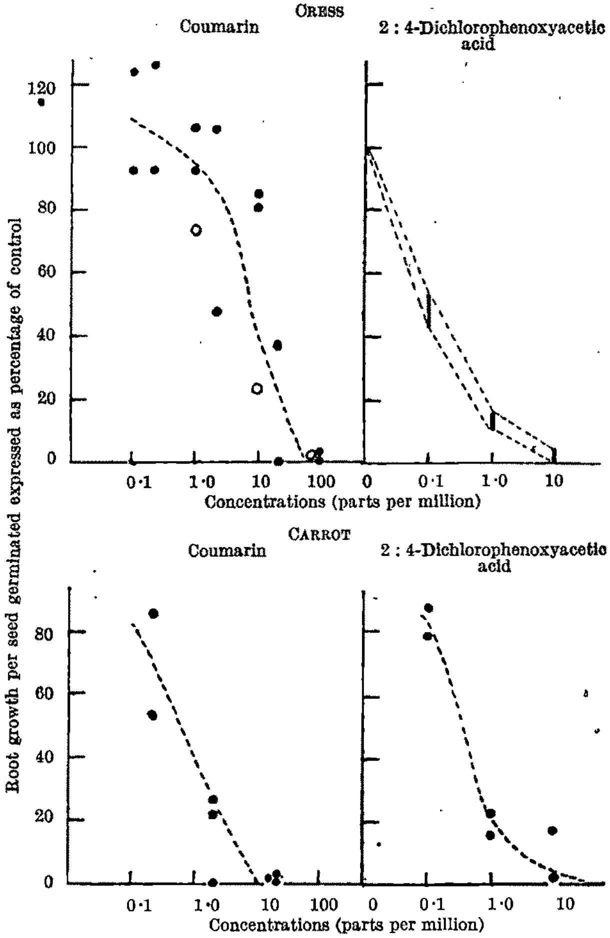

Fig. 1. EFFECTS OF SOLUTIONS OF VARIOUS CONCENTRATIONS OF COUMARIN AND 2 : 4-DICHLOROPHENOXYACETIC ACID ON THE ROOT-GROWTH OF SEEDLINGS OF CRESS AND CARROT

Figs. 1 and 2 show typical results for two of the species investigated, cress and carrot. In order to separate so far as possible the two physiological effects, namely, on germination and on the subsequent root-growth, root weights have been calculated as a sample average per seed germinated. In Fig. 1 these values are expressed as percentages of those in the control tubes in each case. A large amount of data has been accumulated (approximately twenty experiments) on the effects of 2 : 4-dichlorophenoxyacetic acid on root growth of cress, and in the relevant graph the growths are plotted as vertical lines about the mean value. These lines have a range equal to the standard error on either side of the mean.

From the two sets of graphs the following main points stand out:

(1) Coumarin exerts a dual effect, namely, a marked inhibition of both germination and root-growth subsequent to germination. Root-growth is slightly more susceptible than germination. In contrast to this, 2 : 4-dichlorophenoxyacetic acid shows no significant effect on germination over the range of concentrations used, although root-growth is reduced to very low values in the highest concentrations of 10 parts per million.

(2) The action of coumarin is a differential one, carrot being about twenty times as sensitive as cress, whereas these two plants appear to be equally sensitive to 2 : 4-dichlorophenoxyacetic acid.

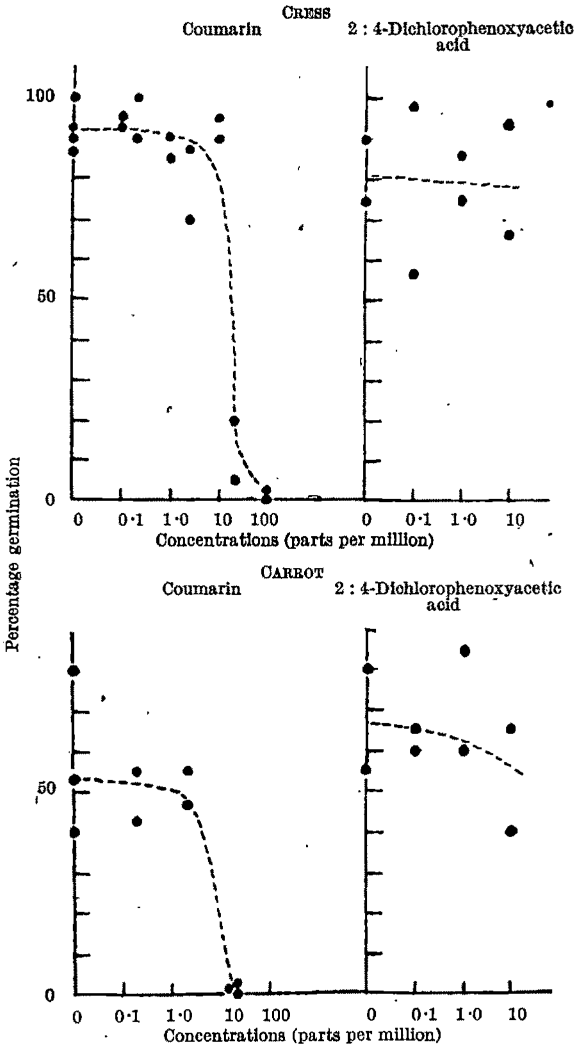

Fig. 2. EFFECTS OF SOLUTIONS OF VARIOUS CONCENTRATIONS OF COUMARIN AND 2 : 4-DICHLOROPHENOXYACETIC ACID ON THE GERMINATION OF CRESS AND CARROT

In all, nine widely different species of plant have been tested. From graphs similar to those of Figs. 1 and 2, the accompanying table has been drawn up showing the concentrations in parts per million of coumarin and 2 : 4-dichlorophenoxyacetic acid necessary to reduce the root-growth and the germination to 50 per cent of the control values in each species.

Species	50% inhibition of root growth		50% inhibition of germination	
	Coumarin (p.p.m.)	2 : 4-Dichlorophenoxyacetic acid (p.p.m.)	Coumarin (p.p.m.)	2 : 4-Dichlorophenoxyacetic acid (p.p.m.)
Cress	11	0·2	11	Greater than 10 in all cases
Radish	8	0·6	10	
Mustard	8	0·15	>20	
Carrot	0·5	0·3	5	
Onion	15	0·3	>20	
Mixed lawn grass	4	>10	4	
Beetroot	12	0·11	>20	
Taraxacum officinale	10	6·0	6	
Cabbage	50	0·04	4	

From this table it will be seen that coumarin exerts the same order of differential action as 2 : 4-dichlorophenoxyacetic acid itself, although on the average, so far as root-growth is concerned, it is between a tenth and a hundredth as effective. In addition, the differential action does not run parallel; for example, whereas cabbage and cress are most sensitive to 2 : 4-dichlorophenoxyacetic acid, they are least sensitive to coumarin. Grass, on the other hand, is more sensitive to coumarin than to the other compound. Carrot is equally sensitive to both.

Formative Effects

Experiments on a number of dicotyledonous species have shown that continued growth of certain species in concentrations of 2 : 4-dichlorophenoxyacetic acid of the order of 1–10 parts per million gave rise to characteristic formative effects on the base of the hypocotyl. This is shown very markedly in radish and to a lesser extent in cress and carrot, where the lower half of the hypocotyl swells to two or three times its normal diameter and becomes translucent in appearance. The histological changes concerned in this are now under investigation. It is interesting to note that coumarin, in concentrations giving the same degree of inhibition of root-growth, also gives similar formative effects on the hypocotyl.

Action of Coumarin in Soil

In addition to experiments in sterile water culture, others have been set up in soil. Small glass pots with a basal vent were filled with air-dry garden soil and then saturated with coumarin solutions of various concentrations (1, 10 and 100 p.p.m.) and allowed to drain. Seeds of the above-mentioned species were then sown in a series of concentrations as in the water-culture experiments, and allowed to germinate. Subsequent watering of the soil was with distilled water, care being taken not to wash out the coumarin with excess water.

Germination and growth gave the same general picture of the effect of coumarin as in the test-tube experiments, but there seemed to be a general all-round reduction in its effectiveness. In addition, seeds, the germination of which had been inhibited in the high concentrations of coumarin, eventually germinated after a lag period of about five days. Subsequent growth was as in the control. It seemed therefore that coumarin, like heteroauxin (β-indolylacetic acid), may be destroyed in soil, and that its inhibition of germination is reversible.

Coumarin Breakdown in Soil

Experiments have been carried out with the assistance of Mr. P. G. Scholefield of this Unit on the breakdown of coumarin in soil, and these will be reported upon in detail in due course. The procedure and results are, briefly, as follows:

A saturated solution of coumarin (100 p.p.m.) was circulated through soil in a soil perfusion apparatus[14] and its rate of disappearance from soil was investigated using a sensitive colorimetric method for the estimation of coumarin. It was found that, following an immediate adsorption of part of the coumarin on the soil, a microbiological attack takes place, and the coumarin disappears completely from the soil, under the given experimental conditions, within forty-eight hours. Certain bacterial poisons inhibit the breakdown of coumarin in soil, and investigations are now being carried out to see if the addition of

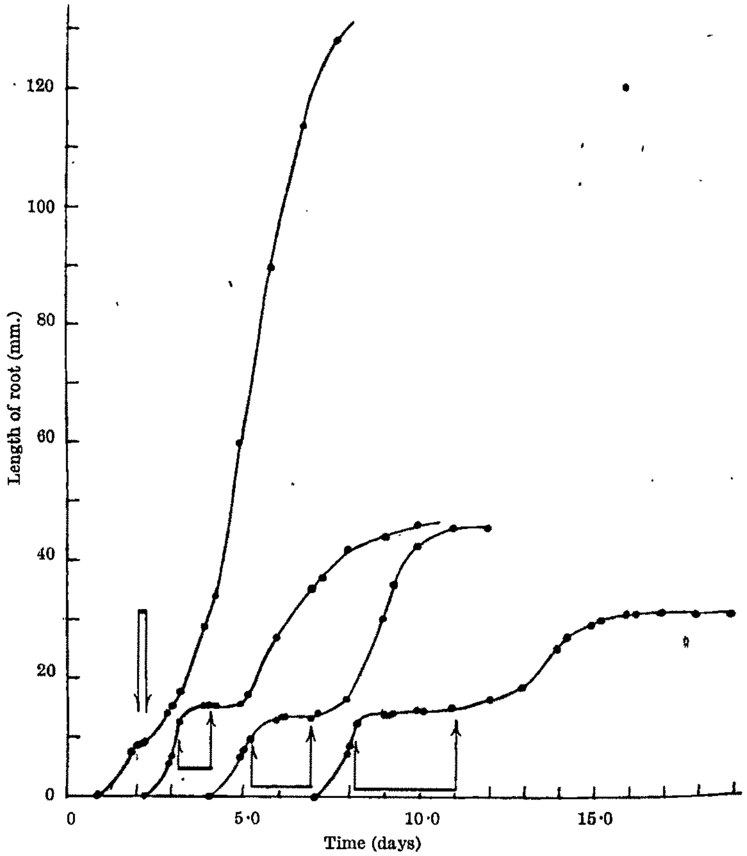

Fig. 3. CURVES SHOWING THE REVERSIBILITY OF THE ACTION OF COUMARIN ON THE GROWTH OF ROOTS OF CRESS. THE POINTS OF ORIGIN OF THE INDIVIDUAL CURVES (THAT IS, TIMES OF COMMENCEMENT OF THE EXPERIMENTS) ARE SPREAD OUT ALONG THE TIME AXIS TO AVOID CONFUSION

such poisons to soil will render coumarin more effective as a phytocidal agent under soil or field conditions.

Reversibility of Action by Coumarin

It is clear that for any understanding of the mode of action of such phytocidal agents as 2 : 4-dichlorophenoxyacetic acid and coumarin, it is essential to know if their inhibitive effects are reversible. If these compounds have toxic effects because they combine in an irreversible manner with cell constituents, their effects will be irreversible, and washing the plant tissue to remove the toxic agent will not result in renewed growth of the plant. On the other hand, if these agents act by forming easily dissociated compounds with tissue constituents, whether they are enzymes or metabolites, washing the plant tissue to remove the toxic agent should result in renewed growth of the plant, so long as autolytic processes have not advanced too far during the interval of time in which growth has not taken place.

We have carried out experiments on the reversibility of action of 2 : 4-dichlorophenoxyacetic acid and of coumarin, and it is clear that, with both substances, reversibility does take place. We propose to give the results of experiments with coumarin, while the details of the work with the other substance will be reported upon later.

Two types of experiment were carried out :

(1) *Reversibility of inhibition of germination.* Cress seeds were soaked in saturated coumarin solution and stood aside in the dark. At intervals of twenty-four hours, the seeds were removed and supported on the surface of a constant, slow-running stream of water-culture solution. Control seeds germinated twenty-four hours after soaking at 20° C. Seeds removed from the coumarin solution after 1, 2, 3 and 4 days, and then washed, all germinated about 36–48 hours after washing, with subsequent normal growth. Longer exposure to coumarin solution of this concentration resulted in complete destruction of the germinative capacity of the seeds.

(2) *Reversibility of the inhibition of root-growth.* In addition to experiments on germination, observations were made on the reversibility of coumarin action on the growth of cress roots. In these experiments, individual seeds were germinated and grown in an aerated water-culture solution which was constantly circulated over them, and the growth of roots was followed by means of a travelling microscope reading to 0·02 mm. Full details of the apparatus and methods will be published in a later paper.

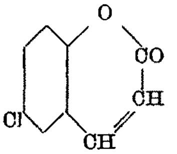
It was found that the addition of coumarin to the circulating solution has the same effects on the growth of individual roots as those observed by the test-tube technique. The open circles in the first graph of Fig. 1 show the values obtained by this method. Experiments were carried out by exposing the root to a circulating culture medium containing 100 p.p.m. of coumarin for varying periods of time and then replacing with pure culture solution. The graph of Fig. 3 shows typical effects of this procedure on the growth of roots of cress. The pairs of vertical arrows mark the duration of the exposure to coumarin in each case (in this experiment 6, 22, 40 and 68 hours). It will be seen that 100 p.p.m. of coumarin gradually reduced the growth-rate to zero during a period of 12–18 hours, and that replacing in fresh circulating culture medium brings about partial recovery. The degree of this partial recovery seems directly correlated with the time of exposure to the coumarin.

Insufficient experiments have been carried out, so far, to do more than make it clear that when a seedling has ceased to grow in coumarin solution for periods up to two or even three days, recovery can take place. It is scarcely to be expected that the recovery will be more than partial; first, because it is unlikely that washing, however good, will remove all the toxic agent, and secondly, because, during the period in which growth is not occurring, autolytic processes must be taking place to the detriment of the subsequent growth. Studies of the chemical events occurring in the plant during the period of inhibited growth should help to throw light on the chemical mechanisms underlying the action of the phytocidal agents. Further experiments have shown that recoveries from the inhibitive effects of coumarin or 2 : 4-dichlorophenoxyacetic acid may be more complete in certain plant species than in others.

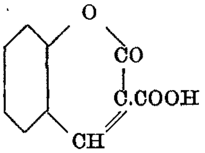
Effects of Coumarin Derivatives

Two derivations of coumarin have been synthesized by Mr. P. G. Scholefield and have been tested to see if they have phytocidal activities. They are:

(i) Monochlorcoumarin



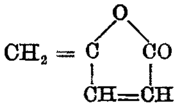
(ii) Coumarin-carboxylic acid



Tested on the carrot, monochlorcoumarin has about one twenty-fifth the inhibitive effect of coumarin on the growth-rate, and one quarter the inhibitive effect of coumarin on the germination. The coumarin-carboxylic acid has about one half the inhibitive activities of monochlorcoumarin. These results make it clear that the presence of substituents may greatly affect the phytocidal activity of the unsaturated lactone ring. Moreover, they emphasize the contrast between coumarin and phenoxyacetic acid, for in the latter the introduction of a chlorine atom into the benzene ring results in increased phytocidal action.

Protoanemonin and Ranunculin

We have been able to carry out experiments with ranunculin (kindly supplied to us by Dr. R. Hill), the diglucoside of protoanemonin, and with protoanemonin itself



as possible phytocidal agents.

Preliminary experiments have shown that protoanemonin is much more effective, and ranunculin is slightly less effective, than coumarin in suppressing the root-growth and the germination of cress.

Conclusions

The most important fact which emerges from this work is the dual nature of the phytocidal activity of coumarin; namely, inhibition of both germination and subsequent root-growth. With respect to the inhibition of root-growth, one feature of the activity of coumarin is its broad similarity to the action of 2 : 4-dichlorophenoxyacetic acid and other phytocidal agents of the heteroauxin class. Although it is only active in this respect at relatively high concentrations (of the order of 10 parts per million), its differential effects are just as clearly defined as, and its formative effects are apparently identical with, those of 2 : 4-dichlorophenoxyacetic acid. Moreover, in the case of at least one plant, carrot, the inhibitive effects of coumarin at a concentration of one part in two millions are as great as those of 2 : 4-dichlorophenoxyacetic acid.

With respect, however, to the inhibitive effects on germination, coumarin is much more active with certain plants than 2 : 4-dichlorophenoxyacetic acid, which in the highest concentrations used (10 parts per million) has no suppressing effects on germination. The two substances also differ in that their differential effects do not run parallel.

The inhibitive effects of coumarin are reversible, and extensive observations (to be reported) with cress and garden pea show that the action of 2 : 4-dichlorophenoxyacetic acid is also reversible. The facts indicate that these substances must effect their inhibitions by forming loose combinations, or easily dissociated compounds, with enzymes or metabolites in the plant cell.

AN ARMAGH–DUNSINK–HARVARD TELESCOPE

By Dr. E. M. LINDSAY
Director of Armagh Observatory

PLANS for the setting up of a Baker–Schmidt telescope on the site of the Boyden Station of the Harvard Observatory, Bloemfontein, South Africa, are now complete. It will be the first instrument of its kind in the world, and will also be a noteworthy example of inter-country international co-operation. The instrument will be operated jointly by the Armagh Observatory, Northern Ireland; the Dunsink Observatory, Dublin, Eire; and the Harvard Observatory, Cambridge, U.S.A. It will be known as the Armagh–Dunsink–Harvard Telescope. The Governments of Northern Ireland and of Eire have each promised to contribute £5,000 towards the cost of the new instrument, and Harvard Observatory will provide the rest of the funds. Harvard will also provide appropriate caretaking and maintenance service, the necessary power and light for the proper operation of the instrument, and access to library and dark-rooms for all observers. The observing time with the instrument will, however, be shared equally by all three Observatories.

The main mirror of the new telescope will be of 36-in. aperture, the secondary mirror of not less than 16-in. and the correcting plate of not less than 30-in. diameter. The famous 24-in. Bruce refractor of the Harvard Observatory will be dismantled, and its mounting and drive will be used for the Baker–Schmidt. It is expected that the new reflector will be about three times as fast as the Bruce. The present 24-in. prism of the Bruce will be re-figured, or a new objective prism manufactured.

Four months of observing in South Africa should provide for each observer approximately three years of research. Thus an observer need spend only about ten per cent of his time away from his own Observatory. The new telescope will require an increase of staff at the Armagh Observatory. To provide for this, the Government of Northern Ireland has promised to give an increased annual grant to the Observatory. The Government of Eire has taken over Dunsink Observatory, which will be re-opened and will be incorporated in a new school of cosmic physics attached to the Dublin Institute of Advanced Studies.

The new Armagh–Dunsink–Harvard telescope will help to fill the long-felt need for more observational material from the southern hemisphere. It will be ideally suitable for such varied problems as galactic structure, variable stars, spectrophotometry, standard photometry, galactic nebulæ, external galaxies and, possibly, statistical radial velocities.

Harvard will be responsible for the design of the reflector, and the Perkin–Elmer Corporation, Glenbrook, Connecticut, has already started on its manufacture. It is hoped that the instrument will be in operation within eighteen months.

INTERNATIONAL COMMITTEE OF WEIGHTS AND MEASURES

AFTER an interval of nine years, the International Committee of Weights and Measures held its first plenary session since 1937 during October 22–29, 1946. The meetings of the Committee which should have taken place in 1939 could not be held owing to the outbreak of war, and the only other meeting which has been possible in the meanwhile was an unofficial one of a few members in 1945 to prepare the way for the recent session. By its constitution, the members of the Committee, which functions under the authority of the treaty known as the "Convention du Mètre", must all be of different nationalities. On this occasion the members present were MM. Louis de Broglie (France), G. Cassinis (Italy), M. Chatelain (U.S.S.R.), E. C. Crittenden (U.S.A.), M. Dehalu (Belgium), W. J. de Haas (Holland), E. S. Johansen (Denmark), W. Kösters (Germany), Z. Rauszer (Poland), M. Ros (Switzerland) and J. E. Sears (Great Britain), together with M. A. Pérard, director of the Bureau International des Poids et Mesures.

The Committee had first to record, with deep regret, the deaths, since its last meeting in 1937, of six former members: MM. B. Cabrera (Spain), Ch. Fabry (France), D. Isaachsen (Norway), A. E. Kennelly (U.S.A.), V. Volterra (Italy) and P. Zeeman (Holland). In the passing of six such distinguished men of science from its numbers, including both its president, M. Volterra, and secretary, M. Cabrera, the Committee has suffered a very severe loss. No news has been received of Prof. Nagaoka, the Japanese member, since 1939, and it is not at present known if he is still alive.

Mr. J. E. Sears was elected president for the current session, and M. Dehalu was elected secretary. M. Pérard presented, and briefly outlined the main features of, his report on the activities of the Bureau International for the period September 1, 1939–August 31, 1946. This was referred for more detailed study to two sub-committees, the Commissions des Travaux, and des Finances, respectively.

The Committee reviewed and confirmed the decisions taken provisionally by the unofficial meeting in 1945. A letter was then read from the French Government asking that, for the future, the Conservatoire des Arts et Métiers should be regarded as the French National Metrological Laboratory, eligible to nominate technical experts, on the invitation of the International Committee, to serve on its Advisory Committees for Electricity, Photometry and Thermometry. This was agreed to.

At their second meeting the members of the Committee made the usual formal visit of inspection to the vault at the Bureau, where the International Prototype Metre and the International Prototype Kilogramme are preserved. They were able to see the reinforcement which had been built into the vault to protect it from the possible shock of bombardment, and noted with satisfaction that, although several bombs actually fell in the grounds of the Bureau, no damage whatever occurred to any of the invaluable standards contained in the vault.

The Committee then proceeded to the consideration of the Report of the Commission des Travaux on the work of the Bureau during the past seven years. It is satisfactory to be able to record that, in spite of difficulties arising from war conditions, the Bureau has been able to make good progress with its programme. In particular, new sections for the comparisons of electric and photometric standards have been installed to deal with the additional duties entrusted to the Bureau following the revision of the Convention du Mètre in 1921.

The Report contains an interesting account of the re-comparison—the first since its original adoption in 1889—of the International Kilogramme with its *témoins*—the working standards of the Bureau. The results obtained agreed with those found in 1889 within 0·05 mgm. in every case, and within 0·01 mgm. in the mean. This, however, was only attained after special cleaning of the weights, first with chamois leather, moistened with benzine, and then with a jet of steam. Prior to this treatment the maximum change recorded was 0·083 mgm., with an apparent increase in the mean value of the *témoins*, relative to the International Kilogramme, of 0·045 mgm.

Improvement has been effected in the accuracy of comparison of the metre standards (*a*) by re-engraving some of those (other than the International Metre itself) which had defining lines inferior to the best attainable by modern means, and (*b*) by the introduction of microscopes on the comparator adapted to rotate about their axes so that the effects of any asymmetry in illumination can be eliminated. It is claimed that as a result of these measures the accuracy of comparison of two metre standards is now within ±0·1 micron. The working standards of the Bureau, which were dispersed for safety during the War, have been re-compared, with results agreeing within this figure with their former values. The possibility of adopting a unit of length defined in terms of a wave-length of light was discussed, but further experimental work is considered necessary before final effect could be given to this proposal.

A proposal that the Bureau should undertake a new determination of the value of gravity, by direct cinematic observation of a freely falling body, was approved by the Committee. A further suggestion, to undertake a new determination of the velocity of light, was negatived on the ground that it was considered to be outside the terms of reference of the Bureau.

The Report of the Commission des Finances showed that the accounts of the Bureau had been properly kept. A number of States, particularly those which have been in enemy occupation during the War, are in arrears with their subscriptions, and the Committee discussed the steps necessary to regularize the position. The present arbitrary rate of exchange of the French franc has been a cause of difficulty to the Bureau, and a recommendation to ask the next Conférence Générale for an increased rate of subscription was accepted by the Committee.

The Committee then proceeded to a consideration of the membership of the three advisory committees. In addition to the Conservatoire des Arts et Métiers, to which reference has been made above, the national laboratories invited by the International Committee to appoint representatives on these committees are: the Bureau of Standards, Washington; the Institut de Metrologie, Leningrad; the Laboratoire Electrotechnique, Tokyo; the National Physical Laboratory, Teddington; and the Physikalisch-Technische Reichsanstalt, Charlottenburg. Further, three independent specialists in the respective subjects, together with the presidents of these committees, are directly nominated by the International Committee. M. Chatelain having declined the office on the ground that he lived too far away from Paris, Mr. Sears was elected president of the Advisory Committee for Electricity. Mr. Crittenden was elected president of the Advisory Committee for Photometry, and M. de Haas president of the Advisory Committee for Thermometry. M. Lombardi was re-elected a member of the Advisory Committee for Electricity, and it was agreed that the International Electro-technical Commission should be consulted as to the two remaining vacancies. Messrs. Bordoni (Italy), Pirani (Germany) and Zwikker (Holland) were re-elected to the Advisory Committee for Photometry, and Messrs. Perucca (Italy), Timmermans (Belgium) and Zwietosławski (Poland) were elected to the Advisory Committee for Thermometry.

The most important business before the International Committee arose from the recommendations of the advisory committees at their previous meetings in June 1939, in particular, that absolute electrical units, based on the M.K.S. (or the C.G.S.) system, should be substituted for the present international electrical units, based on the mercury ohm and the silver voltameter, and that a new unit of candle-power, based on the luminous intensity of a black-body radiator at the temperature of solidification of melted platinum (60 units per cm.^{2}), should be substituted for the present international candle, as from January 1, 1940.

As the International Committee had not met since these recommendations were made, it had not been possible to implement them at the date proposed. The Committee, having already been empowered to that effect by the General Conference of 1933, has now decided that these proposals should be put into force as from January 1, 1948, and notification of this decision is being sent to the Governments of all the States subscribing to the Convention. No difficulty arose with regard to the new unit of candle-power which, it is understood, has already been adopted in Germany. The decision in this case was unanimous. With regard to the proposed change in the electrical units, objection had been raised by the Physikalisch-Technische Reichsanstalt; but the Committee held that it was important that the decision on this question should not be further delayed, as unless the change were to be made soon it was likely to become increasingly difficult to make it at all. In this case the decision was that of a majority, with one dissentient.

The ratios of the principal international to the corresponding absolute electrical units accepted by the Committee are:

1 mean international ohm = 1·00049 ohm (absolute).

1 mean international volt = 1·00034 volt (absolute).

The recommendation of the Advisory Committee for Thermometry, that the calorie should be defined directly in terms of the joule, instead of by reference to the specific heat of water, was regarded as of less urgency and, as some objection had also been received to this proposal, it was agreed to defer a decision on it until the Advisory Committee had had a further opportunity of considering it.

OBITUARIES

Sir John Flett, K.B.E., F.R.S.

By the death of Sir John Smith Flett, British geology has sustained the loss of one of its most distinguished exponents, with an established reputation both at home and abroad. His career affords a remarkable example of the original research worker and able administrator, and his place is assured in the long line of distinguished geologists who have directed the work of the Geological Survey and Museum during the last 111 years.

Flett was born in 1869 in Kirkwall, Orkney, and was educated at Kirkwall Burgh School, then at George Watson's College, whence he proceeded to the University of Edinburgh. His academic career was prophetic in its brilliance and versatility, and was marked by the award of a unique and imposing array of prizes, medals and scholarships in the Faculties of Arts, Science and Medicine. He graduated M.A., B.Sc. (with honours in natural science) in 1892, M.B., C.M. in 1894, and spent a short time in medical practice. The urge towards geological work, however, was strong within him, and in 1895 he accepted the post of assistant to the professor of geology (then James Geikie) in Edinburgh, and very shortly afterwards was appointed lecturer in petrology. Concurrently with that post he held lectureships in geology at the Heriot-Watt College, the East of Scotland School of Rural Economy, and the School of Forestry in the Royal Botanic Garden. There followed six strenuous years of teaching, lecturing and research work resulting in part in the publication of two outstanding papers, "The Old Red Sandstone of the Orkneys" and "The Trap Dykes of the Orkneys", accepted in 1899 by the University of Edinburgh as a thesis for the D.Sc. degree.

Flett's reputation as a geologist and petrographer was steadily growing, and when, in 1901, the late Sir Jethro Teall relinquished the post of petrographer to become director of the Geological Survey and Museum, the young man from Scotland was offered and accepted the vacancy. He speedily made his influence felt. Familiar with the most recent methods of research, a skilled mineralogist, widely read in the literature of his subject, and possessed of energy, enthusiasm and a formidable capacity for constructive work, he set in motion a continuous flow of published reports, papers and contributions to official memoirs which permanently enhanced the reputation of the service to which he belonged. He attracted to his laboratory many of the younger Survey men of his time. These he trained in his methods, and inspired and encouraged not a few of them to original research and subsequent distinction within and without the Survey. The output of his scientific work during this period was truly remarkable, comprising as it did petrographical contributions to no fewer than thirty official memoirs, the classic "Report on the Eruptions of the Soufrière in St. Vincent, in 1902, and on a visit to Montagne Pelée, in Martinique" (with Tempest Anderson), "The Geology of the Lizard and Meneage" (with J. B. Hill), and numerous contributions to scientific journals some of which were written in collaboration with his colleagues. In addition he contributed eighty-three petrological articles to the "Encyclopædia Britannica" (11th edition, 1910), and it is noteworthy testimony to the soundness and permanence of his work that thirty-three of these contributions appear in the 14th edition (1929).

In 1911 Flett succeeded the late Dr. John Horne as assistant to the director in Scotland, and thereafter became more and more immersed in Survey business and administration. He took an active and personal interest in every branch of Survey work, made extended visits to the field and familiarized himself with the numerous problems which constantly arise in the production and publication of geological maps and memoirs. The outbreak of war in 1914 caused serious depletion of the Survey staff, many of whom volunteered and were accepted for active service, and at the same time imposed on the directorate new tasks and responsibilities in the search for, and assessment of, available resources of raw materials in short supply, and in meeting insistent demands for geological information relating to the sites of camps, training centres, aerodromes and factories at home and to military operations overseas. Flett tackled these new tasks with characteristic energy. He not only organised and directed the Scottish section of the work but also undertook a considerable amount of field investigation and made substantial personal contributions to the numerous reports prepared for the information of service and supply departments. His reputation as geologist, petrographer and administrator was now firmly established and fully justified his selection in 1920 to succeed the late Sir Aubrey Strahan as director of the Geological Survey and Museum, a post he filled with conspicuous distinction and success for fifteen years.

The record of achievement of the Geological Survey and Museum during this period is an impressive one. The arrears of work, an inevitable legacy of four years of war, were rapidly overtaken, the staff was enlarged and reorganised, district offices were established in the coalfields, and the work of bringing up to date and publishing the geological information relating to these vitally important areas was prosecuted with an unprecedented vigour and resulted in a steady outflow of maps, memoirs and special reports. Nor were the purely scientific aspects of geology neglected. The surveys of the great volcanic complexes of Mull and Ardnamurchan were completed and the results embodied in maps and memoirs which stand unrivalled as classic records of perhaps the most complicated structures ever mapped by the Geological Survey. Similarly, the extensive complexes of schist and granite of central and northern Sutherland were mapped and described, and the field survey of the Orkney and Shetland Islands was completed.

Throughout this period of strenuous activity Flett steadily pursued the scheme, proposed in 1912 by the Bell Committee, for the transference of the Geological Survey and Museum from the inadequate and congested accommodation in Jermyn Street to a new and more spacious building in South Kensington. The culmination of his efforts came in July 1935, when the King (then Duke of York) formally opened the new Geological Museum and Survey offices in Exhibition Road, and the institution, served so long, so devotedly and to such purpose, celebrated its centenary. Two months later Flett retired from the public service. In his retirement he continued with characteristic energy his geological pursuits and his deep interest in all matters connected with the Survey and Museum. He saw through the press his memorial volume, "The First Hundred Years of the Geological Survey", written during the last period of his directorship, revised the Lizard map and prepared a second edition of the memoir now being printed, and took the greatest pleasure in stimulating his colleagues and "his young men" to fresh endeavour for his beloved science. Active to the end, he died with startling suddenness in the garden of his cottage at Ashdon, Essex, on January 26.

Many honours came to Flett in the course of his long and brilliant career. He was a fellow of the Royal Societies of London and Edinburgh, Bigsby and Wollaston Medallist of the Geological Society, LL.D. of his own University, created K.B.E. in 1925, president of Section C of the British Association in 1921, president of the Mineralogical Society, and member and correspondent of numerous societies in the Dominions and foreign countries where he had travelled extensively. But what he valued most of all was the satisfaction of endeavour and achievement, and his name is permanently woven into the fabric of Survey history and tradition as a great geologist and a great director. W. F. P. McLintock

Prof. George L. Funke

Prof. George L. Funke, professor of botany in the University of Ghent, died on December 15 at the age of fifty, after an operation. He was Dutch, born at The Hague on May 29, 1896, and was educated at Amsterdam and Utrecht. He graduated at the University of Utrecht in 1922 with a doctorate in botany and zoology. After some years as lecturer in Holland, he went in 1934 to Belgium as a lecturer at the University of Ghent, where he became an ordinary professor in 1937; during the War and the German occupation of Belgium, he was forced to go back to Holland, being deprived by the Germans of his post, which he resumed, however, in 1945.

Prof. Funke, who was unmarried, displayed an uncommon energy and an almost youthful enthusiasm in every kind of activity he took up; as director of the Botanical Laboratories at the University of Ghent, he paid much attention to the practical side of his work, and defended, at times against powerful odds, the teaching of biology in schools. His purely scientific work was of importance, particularly with regard to the question of the influence of the light on plant development. Inspired by the investigations of Dr. Fröschel, he developed a new branch of botanical science which may be called 'experimental plant sociology'; a book on this subject, it is expected, will shortly be published in the United States.

P. van Oye

Dr. Victor Robinson

THOSE who had known Victor Robinson only through his writings were unwilling at first, when they met him face to face, to associate this modest, hypersensitive, and extremely genial little man with so dramatic, fiery and sentimental a pen. Nevertheless, as a historian he was painstakingly accurate, being most scrupulous in going to the original sources.

The son of a medical man, Robinson was born in the Ukraine on August 16, 1886, emigrating to the United States of America in infancy. One of the first to specialize in the history of medicine in that country—he used to confess that his interest in the subject gave him the same sort of satisfaction as the devotee of hasheesh derives from his pipe—in 1912 he published one of his best known and most popular books, "Pathfinders in Medicine", for which he was hailed as the "Poet of Science". Eight years later he founded *Medical Life*, stated to be the first monthly journal of medical history in the English language. Specializing in valuable medico-historical symposia, at one period it served as the official organ of the American Society of Medical History. Beginning with the October 1922 issue the section on clinical medicine was eliminated. Its editorial board included such distinguished historians as Castiglioni, Comrie, de Lint, Ebstein, Neuburger, Sigerist, and Sudhoff. Robinson's last book, "Victory over Pain : a History of Anesthesia", was published in New York late last year, and it is interesting to be reminded that the author's first contribution to the literature of medical history was an article on "Simpson on Chloroform", and that his name was first listed in the "Index Medicus" under the heading of "Anesthetics".

Robinson was professor of the history of medicine at Temple University Medical School, Philadelphia, and lecturer on the history of nursing. He occupied a delightful apartment in New York's Greenwich Village. His medico-historical library was enviably complete, making him more or less independent of the City's reference libraries. Though an apparently facile writer, he was a tremendously hard worker, the German word *Sitzfleisch* being often on his lips. One of his most novel and entertaining essays appeared in the *Medical Review of Reviews* in 1929, describing his experiences with the fluid extract of hasheesh. In the introduction to "Pathfinders in Medicine", Victor Robinson characteristically admitted having entered the field of medical history as he had entered several others—out of curiosity. "But the fruit was tempting, and I have gathered it ever since."

W. R. BETT

NEWS and VIEWS

An International Trust for Zoological Nomenclature

IN view of the rapid growth in recent years in the volume of its work, the International Commission on Zoological Nomenclature (which is an unincorporated body of eighteen international commissioners elected by the International Zoological Congress) recently decided that an incorporated body should be formed for the purpose of managing its financial and other business affairs. For this purpose a body has now been incorporated under United Kingdom law with the title "International Trust for Zoological Nomenclature". At the same time an agreement has been made between the International Commission and the International Trust by which the Commission has transferred its assets to the Trust and the Trust has accepted responsibility for all the liabilities of the Commission. Under the new arrangements, the Commission will continue all its scientific functions, while the Trust will be responsible for publishing the Commission's "Opinions" and other publications, for meeting the administrative expenses of the Commission, and for carrying out such further developments as may be decided upon by the Commission. The full text of the instrument of incorporation will be published as soon as possible in the Commission's "Bulletin of Zoological Nomenclature".

The closest liaison between the Commission and the Trust is assured by arrangements under which the members of the Commission will be members of the Trust, and the secretary to the Commission will be *ex-officio* secretary to the Trust. In addition, the Trust has taken over, as its registered office, the premises at 41 Queen's Gate, London, S.W.7, hitherto occupied by the Commission as its publications office. In order to ensure that there shall at all times be a sufficient number of members available to attend meetings of the Trust, the Commission has arranged for the appointment as members of the Trust of certain of the honorary unpaid officials of the Commission. At the invitation of the Commission, the chairmanship of the Trust has been accepted by the Right Hon. Walter Elliot. The arrangements outlined above will provide the Commission with a strong administrative organisation and also enable it to concentrate the whole of its efforts upon furthering the orderly development of zoological nomenclature.

New University at Olomouc

THE difficulty of accommodating all students in the existing Czechoslovak universities has led to the opening of a new one at Olomouc in north Moravia. The ceremony took place on February 21 after a special train from Prague had brought President Beneš, members of the Czechoslovak cabinet, Sir Phillip Nichols (the British Ambassador) and other diplomatic personalities to Olomouc. The new university is named after Palacký, the Czechoslovak historian so long associated with both the Charles University and the National Museum of Prague; and in his speech Dr. Beneš referred to the fact that Prague's university had existed for almost six hundred years, and that the name of Palacký could appropriately be given to the new university in recognition of the historian's cultural work for the nation a hundred years ago. He said that the importance of education is fully realized in Czechoslovakia, where it is vital for a small nation to be in the forefront of progress. The immediate task is to overtake the years lost through the War and the German occupation.

The rector of the new university is Prof. J. L. Fischer, a comparatively young philosopher from the University of Brno, already well known on the Continent for his contributions to the modern philosophical approach to social problems. Perhaps better known in Britain is the dean, Dr. V. Lesný, previously professor of Oriental studies at Prague, who has travelled much in India and written several works on Indian culture, some of which have appeared in English. The best known of these is his study of Rabindranath Tagore. Olomouc is not a new centre of culture. It was the seat of an ancient Czechoslovak school in the sixteenth century. In the seventeenth century this became a catholic seminary, and its presses produced some early Slavonic books. The eighteenth century scientific journal, *Monatliche Auszüge*, edited by Joseph Petrasche, was published at Olomouc, then better known by its German name Olmütz.

Geology at University College, Swansea

It is announced that Dr. Duncan Leitch, at present lecturer in geology in the University of Glasgow, has been appointed to succeed Prof. T. Neville George as professor of geology at Swansea. Dr. Leitch was trained under the late Prof. J. W. Gregory, with whom he carried out researches on the metallic minerals of Kirkcudbrightshire and on some caves of Galloway. Most of his subsequent work has related to the palæontology and stratigraphy of the Carboniferous rocks, especially of Scotland, where in collaboration with Dr. John Weir he carried out an exhaustive study of the non-marine lamellibranchs of the Coal Measures and provided a sound basis for the correlation of the seams. In an important series of papers he has developed statistical methods, which are proving of wide application, for the study of fossils. There is great scope for statistical research in palæontology and in other branches of geology; and at Swansea, in close access to the areas where the standard sequence of Coal Measures zones was established, he will find good opportunities to extend these investigations.

Colonial University Grants Advisory Committee

The Secretary of State for the Colonies has, in accordance with a recommendation of the Commission on Higher Education in the Colonies, appointed a Colonial University Grants Advisory Committee to advise him on the expenditure of United Kingdom funds for the development of higher education in the Colonies. On the academic aspects the Committee will be guided by the opinion of the Inter-University Council for Higher Education in the Colonies. The secretary of the Inter-University Council, Mr. Walter Adams, has been appointed secretary of the new Committee also, and the following have been appointed members: Sir Hector Hetherington, vice-chancellor of the University of Glasgow (*chairman*); Miss Myra Curtis, principal of Newnham College, Cambridge; Lord Hailey; Sir James Irvine, vice-chancellor of the University of St. Andrews; Sir Walter Moberly, chairman of the University Grants Committee; Dr. Keith Murray, rector of Lincoln College, Oxford; Prof. D. Hughes Parry, vice-chancellor of the University of London; Dr. R. E. Priestly, vice-chancellor of the University of Birmingham; Mr. D. J. Sloss, vice-chancellor of the University of Hongkong; Mr. C. W. M. Cox, educational adviser to the Secretary of State for the Colonies; Mr. J. B. Williams, Finance Department, Colonial Office.

Experiments on Cosmic Rays in High-Flying Aircraft

A brief announcement has been issued by Dr. Gilbert Grosvenor and Dr. W. F. G. Swann in a News Bulletin of the National Geographic Society of Washington of some experiments on the origin of the meson component of the cosmic rays. The National Geographic Society, the Bartol Foundation and the U.S. Army co-operated in the experiments, which were made in a series of flights in a *B*29 aircraft at places, ranging from Northern Chile to Southern Canada, from the magnetic equator up to mag. lat. 48° N. and at altitudes up to 33,000 ft. The apparatus consisted of a number of coincidence counters arranged to record penetrating particles of which the direction of motion was in or near the vertical. The soft component (electrons and photons) was prevented from reaching the counters by a sufficient thickness of lead shielding. At 33,000 ft. the observed intensity of the mesons, using this particular experimental arrangement, was observed to increase by 33 per cent in going from mag. lat. 0° to mag. lat. 48°, and 50 per cent at 25,000 ft. The absolute change in intensity with latitude, in contrast with the above values of the relative changes, was greater at the higher altitude than at the lower.

The results show, in accordance with previous views, that a considerable fraction of the meson component is produced by primary charged particles, presumably protons, of such an energy that some of them are appreciably deflected by the magnetic field in approaching the earth. The decrease in the percentage variation of the intensity with latitude at increasing altitudes is attributed to the presence of a primary component which produces mesons in lead but is not sensitive to the magnetic field of the earth and is rapidly absorbed between 33,000 and 25,000 ft. This radiation could be made up of photons. The authors prefer, however, to attribute it to protons of great energy. In this case the observations suggest that the cross-section for the production of mesons by fast protons increases rapidly with increasing energy. In support of this view it is found that there is no increase in the meson intensity at 33,000 ft. at latitudes higher than 48° mag. N. A proton of such an energy that it could enter the earth's atmosphere at this latitude would not be stopped by the matter composing the atmosphere down to 33,000 ft. plus the lead of the apparatus if it loses energy only by the normal processes of ionization. The observed absorption must therefore be attributed to other processes which, the authors suggest, are connected with meson production.

Behaviour: An International Journal of Comparative Ethology

Interest in the study of animal behaviour (ethology) is growing rapidly. The results of comparative behaviour studies have in the past been scattered throughout a number of periodicals and other publications. The German *Zeitschrift für Tierpsychologie* was hitherto the only European journal devoted exclusively to the publication of modern behaviour studies; and during its short existence, it demonstrated clearly that a special journal of this kind fulfils a most important function in stimulating and promoting the study of the subject with which it deals; but its future is now in doubt. It has accordingly been decided to found a new international journal of comparative ethology to be called *Behaviour*.

The new journal will cover the scientific study of animal behaviour and will be open to reports of original research on animal behaviour and to theoretical papers calculated to promote the experimental study of the subject. Work on endocrinology and nerve physiology will be given its due share of space, so long as it is clearly related to and designed to illuminate the behaviour of the animal. The editors are Prof. H. Hediger (Basel); Prof. P. Palmgren (Helsingfors); Dr. W. H. Thorpe (Cambridge); and Dr. N. Tinbergen (Leyden). *Behaviour* will appear at first at irregular intervals in issues of about 160 pages, the frequency depending on the amount of material offered for publication and on the availability of suitable paper, etc. The price of a volume of about 320 pages will be about 20 Dutch guilders. It is being published by E. J. Brill of Leyden.

Cambridge Summer School in Metal Physics

A SUMMER SCHOOL in Metal Physics will be held during September 1–12 inclusive in the Cavendish Laboratory, Cambridge. The School will provide an introduction to the application of physical methods to the examination and utilization of metals, and is intended for those whose researches require a more fundamentally physical approach than is usual in ordinary metallurgical and engineering practice. The lectures and demonstrations will deal with (*a*) application of X-ray methods in the examination of metals, (*b*) physical and mechanical properties of metals. Both parts will be taken by all attending the School, and for part (*a*) an elementary knowledge of X-ray diffraction methods and of crystal symmetry will be assumed; during the School it will be possible to provide only a very brief review of these aspects of the subject-matter. A detailed syllabus and form of application for admission can be obtained from G. F. Hickson, secretary of the Board of Extra-mural Studies, Stuart House, Cambridge, to whom the completed application form should be returned not later than June 7.

University of Glasgow

THE bicentenary of the institution of a lectureship in chemistry in the University of Glasgow falls during the present session. Dr. William Cullen was appointed in 1747 and held the lectureship for nine years, being succeeded by Dr. Joseph Black in 1756. To celebrate the bicentenary, four lectures will be given in the Department of Chemistry, on May 9, 16, 23 and 30, by Dr. Douglas Guthrie, on "William Cullen and His Times"; Prof. John Read, on "Joseph Black, the Teacher and the Man"; Dr. Alexander Fleck, on "Scottish Industrial Development of the Cullen/Black Period"; Prof. A. R. Todd, on "Glasgow Chemistry in the Twentieth Century".

Society for Experimental Biology: Utrecht Meeting

THE Society for Experimental Biology is holding a meeting at Utrecht during April 11–14; this is the first foreign meeting which the Society has held. An invitation to hold the meeting in Utrecht was given by the botanists and zoologists of the University of Utrecht, on the initiative of Prof. G. J. van Oordt, who had been a visitor at the Society's meeting last year at Newcastle. Papers will be presented by both British and Dutch workers in the field of experimental biology. A party of about seventy British scientific workers will be visiting Utrecht for the meeting. Many topics will come under discussion, including some aspects of entomology and parasitology, histogenesis, electro-physiology, respiration of both animals and plants, permeability phenomena and plant hormones. On Sunday, April 13, there will be no formal sessions, but two expeditions, one to the reclaimed areas of the Zuider Zee, and the other to the bulb fields; on this evening, all those attending the conference will dine together at Amsterdam.

Servo-Mechanisms

A RAPIDLY growing literature gives some indication of the extent to which war-time developments of automatic control systems or servo-mechanisms are finding application in industry. These applications range from relatively simple remote-position control systems to the overall control of complete industrial processes. A specialized theoretical technique has been evolved for the design of such systems and the analysis of their behaviour. A number of papers on the various aspects of this subject will be presented at a Convention on Automatic Regulators and Servo-mechanisms to be held at the Institution of Electrical Engineers during May 19–23.

Announcements

DR. E. D. MERRILL, Arnold professor of botany at Harvard University, has been made an honorary staff member of the Botanic Gardens, Buitenzorg, Java. A diploma was handed to him by Dr. C. G. G. J. van Steenis, senior botanist of the Gardens, at a dinner for the editorial board of *Chronica Botanica* during the recent Boston meetings of the American Association.

THE Herbert Jackson Prize for 1946 of the London, Midland and Scottish Railway has been awarded to Mr. J. O. Cowburn, formerly engineering research assistant, Derby, for a paper entitled "The Development of a Successful Leakage-Testing Instrument for use on Vehicles fitted with the Automatic Vacuum Brake".

MR. WILLIAM WILLIAMSON, joint author of the Ray Society volumes "The British Hydracarina", vols. 1–3 (1925–29), has presented to the library of the Royal Society of Edinburgh more than a thousand papers and a number of volumes dealing with the Hydracarina. Specimens have been lodged with the Royal Scottish Museum, Edinburgh, the Department of Zoology of the University of Edinburgh, and the British Museum (Natural History), London.

THE X-Ray Analysis Group of the Institute of Physics has recently established an X-Ray Tube Panel, under the chairmanship of Dr. A. Taylor. The Panel will review existing and projected X-ray tubes and X-ray tube production in Great Britain. A questionnaire is being sent to all members of the X-Ray Analysis Group of the Institute and to certain others known to be interested in crystallographic X-ray tubes. Communications should be sent to the honorary secretary of the Panel, Mr. J. N. Kellar, Crystallographic Laboratory, Cavendish Laboratory, Cambridge.

ERRATUM.—In "Role of Sulphydryl Groups in the Action of Acetylcholine and Inhibition of the Vagus Nerve" by Prof. Ch. S. Koschtojanz and T. M. Turpajew published in *Nature* of December 7, 1946, p. 837, paragraph 5, last line, for "cystein" read "cystine".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Determination of the Energy and Momentum of Fast Neutrons in Cosmic Rays

Previous experimenters, working on the multiple disintegration phenomena produced by cosmic radiations, have concluded that some at least of the nuclear explosions are produced by fast neutrons. In approaching the problem of determining the energy of such neutrons, we meet the difficulty that the usual method, in which observations are made on the recoil protons which the neutrons produce by collision with hydrogen nuclei, is not applicable. It is therefore important to develop alternative methods, and, for this purpose, we have examined the possibility of employing the nuclear reaction between boron and fast neutrons.

We first exposed boron-loaded plates to the homogeneous groups of neutrons produced by the bombardment of boron by 900 keV. deuterons from the Cambridge high-tension generator. Provision was made for determining the direction of the neutron flux at any point in the plate with an accuracy of ± 1°, and the plates were placed in such a position that they were exposed to neutrons emitted in the direction of motion of the primary deuterons. In these conditions the mean energies of the fastest two groups of neutrons passing through the plates were 9·6 MeV. and 13·4 MeV. respectively.

A microscopic examination of the exposed plates after development shows, in addition to numerous short tracks due to the reaction

$$\mathrm{B}^{10}_{5} + n^{1}_{0} \rightarrow \mathrm{Li}^{7}_{3} + \mathrm{He}^{4}_{2}, \qquad (1)$$

many three-particle disintegrations. A photomicrograph of one of these events is reproduced in Fig. 1 (*a*). The discriminating power of the emulsion is sufficiently great to allow us to identify the tracks of two α-particles, α_1 and α_2, and a less heavily ionizing particle τ_1, composing the 'star'. We conclude that the disintegration is produced in the well-known reaction[1]

$$\mathrm{B}^{10}_{5} + n^{1}_{0} \rightarrow \mathrm{He}^{4}_{2} + \mathrm{He}^{4}_{2} + \mathrm{H}^{3}_{1}, \qquad (2)$$

of which the Q value, as determined from the masses of the nuclei, is + 0·4 MeV.

From the observed lengths of the tracks and the range-energy relation for tritons and α-particles in the emulsion[2], we can determine the energy of each of the particles. The values so obtained are: particle α_1, 7·4 ± 0·2 MeV.; particle α_2, 1·4 ± 0·4 MeV.; and triton (τ_1), 5·0 ± 0·1 MeV. The total energy is thus 13·8 ± 0·5 MeV., and this corresponds to an energy of the incident neutron of 13·4 ± 0·5 MeV. We can also compare the vector sum of the momenta of the three particles with that of the incident neutron, assuming the latter to have an energy equal to the mean energy of the fastest group of neutrons from the source. We chose the momentum of a proton of energy 0·5 MeV. as a convenient unit. The tracks of the three charged particles are nearly co-planar, and in Fig. 2 (*a*) we represent their momenta in a vector diagram. The resultant momentum is represented in magnitude and direction by the line *OP*, and this is nearly coincident with *OR*, the momentum of the incident neutron—the two magnitudes being 5·6 ± 0·6 units and 5·2 units respectively, and the difference in direction less than 2°. The errors in the determination of the total energy and momentum are mainly due to the uncertainty in the energy of the short-range α-particle, and they would be less if the ranges of the particles were more nearly equal.

In view of the satisfactory results obtained in work with neutrons of known energy and momentum, we next examined boron-loaded plates exposed to the cosmic rays, at the Pic du Midi, at a height of 2,800 m. We found a number of disintegration stars, very similar in form to those produced by the 13·4 MeV. neutrons; an example is reproduced in the mosaic of photomicrographs in Fig. 1 (*b*). From the grain-spacing in the tracks we can identify α_3 and α_4 as α-particles and τ_2 as a particle of charge $+e$. All the tracks end in the emulsion, so that their ranges can be determined; but, owing to the lack of an established range-energy relation extending up to 50 MeV., we can only deduce an approximate value of the energy of the particle α_3. By extrapolating the range-energy curve obtained in previous experiments, we obtain a value of 26·5 ± 1·5 MeV. The energy of particle α_4 is 2·9 ± 0·2 MeV. and, if τ_2 is a triton, its energy is 7·4 ± 0·1 MeV.

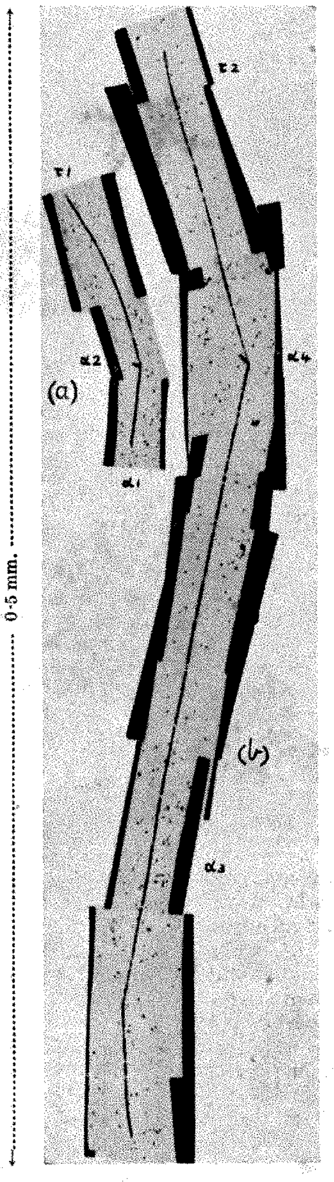

Fig. 1. THE BLACK EDGES OF THE INDIVIDUAL PHOTOGRAPHS HAVE BEEN RETAINED TO SHOW THE METHOD OF MAKING THE MOSAIC. THE PHOTOGRAPHS HAVE NOT BEEN 'RETOUCHED' AT ANY STAGE IN THE PHOTOGRAPHIC PROCESS

If we construct a momentum diagram, Fig. 2 (*b*), we find a value for the momentum of the incident particle of 9·5 ± 0·9 units. Assuming the particle to be a neutron, its calculated energy is 45 ± 8·5 MeV. as compared with the value, obtained from the total kinetic energy of the three particles, of 36·8 ± 1·8 MeV. If, alternatively, we calculate the mass of the incident particle from the observed energy and momentum, we obtain the value 1·23 ± 0·30 mass units.

In view of the uncertainty in the energy of particle α_3, and of the direction of particle α_4, the above result is

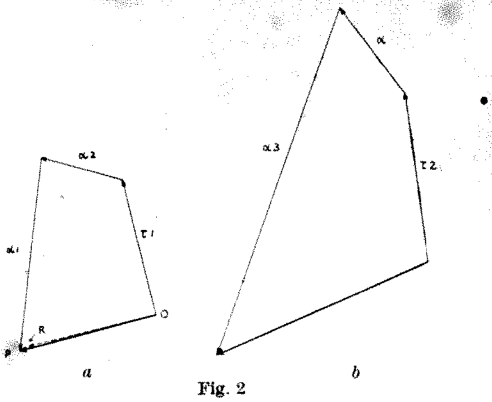

Fig. 2

very satisfactory and makes it certain that the disintegration was produced by a fast neutron and not by the photo-disintegration of a boron nucleus. We conclude that determinations of the energy and momentum of fast neutrons can be made with boron-loaded plates. Owing to the short range of tritons and α-particles, as compared with protons of the same energy, and the division of the energy among three particles, it may be possible, with thick emulsions, to apply the method in experiments with neutrons of energy up to 100 MeV. and possibly higher.

It must be anticipated that, as the energy of the intermediate nucleus increases, there will be a growing tendency for the proton and two neutrons, which at lower energies appear together as a triton, to be emitted as separate particles. It can be shown, however, that in very few cases will there be consistency between the observed energy and momentum if a star, produced in fact from a reaction involving neutron emission, is interpreted as due to reaction (2). In such cases, if we make reasonable assumptions about the distribution of the emitted neutrons, we can show that the probability that the calculated mass of the incident particle will depart from unity by amounts less than the 'probable error' is small. In the particular case of the star shown in Fig. 2 (*b*), it is 8 per cent. Further, in ambiguous cases, it may be possible, with improvements in the discriminating power of the emulsions, to distinguish the tracks of tritons from those of protons and deuterons. Although it is possible to get better discrimination between the various types of fast particles by using the *C*1, *E*1 and *D*1 series of emulsions, we have found that they cannot be employed for work in cosmic rays where long exposures are necessary because of the rapid fading of the tracks[2]. In the present experiments we employed *C*2 and *B*1 emulsions, in which the fading after a month is not so serious. We may emphasize that the other light elements may also be employed for this type of work. Beryllium and lithium are of particular interest because the modes of disintegration are simple.

The present results illustrate an important general feature of the photographic method. Because it is possible to determine the energy and the momentum of all the charged particles, arising from the disintegration of a nucleus in the emulsion, the method is particularly suitable for the study of individual disintegrations, especially those in which more than two particles are emitted.

The investigation of the various modes of disintegration of boron under fast neutron bombardment, including an examination of the angular distribution of the disintegration particles, is continuing, and a complete account of the experiments will be published elsewhere.

We have pleasure in thanking Dr. W. E. Burcham and Mr. D. L. Livesey for their kindness in making it possible for us to obtain exposures to fast neutrons from the Cavendish high-tension generator. We are greatly indebted to Prof. J. Baillaud, director of the Observatory of the Pic du Midi, to Dr. Hugon and to Prof. Max Cosyns for assistance in obtaining the exposures to the cosmic rays. We wish to express our gratitude to Dr. C. F. Powell for many discussions, and for generous assistance.

Emission of Light Charged Particles in the Fission of Uranium

AT the Physical Society's Conference on Fundamental Particles, held at Cambridge in July 1946, we reported that a light charged particle is occasionally emitted in the fission of uranium by slow neutrons, in addition to the two heavy fragments. This was observed during an examination of fission fragment tracks produced in Ilford photographic emulsions by a method which we have previously described[1]. Similar observations have recently been reported by Tsien, Chastel, Ho and Vigneron[2].

In a detailed investigation of this phenomenon, we have examined 25,000 fission tracks using emulsions which were sensitive to α-particles and heavier

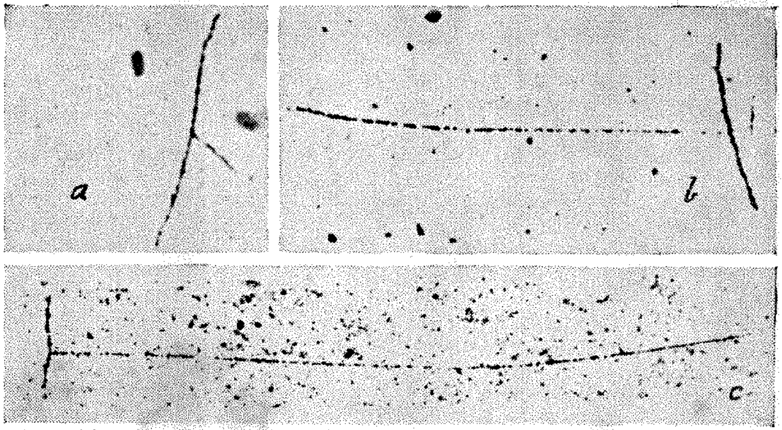

Fig. 1. (*a*) LIGHT-PARTICLE RANGE = 5·5 μ (0·87 CM. AIR EQUIVALENT). (*b*) LIGHT-PARTICLE RANGE = 53 μ (9·5 CM. AIR EQUIVALENT). (*c*) LIGHT-PARTICLE RANGE = 132μ (24 CM. AIR EQUIVALENT).

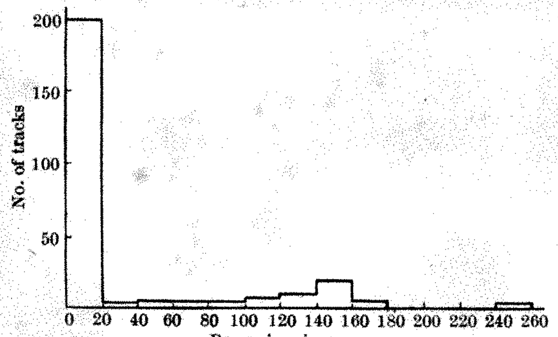

Fig. 2

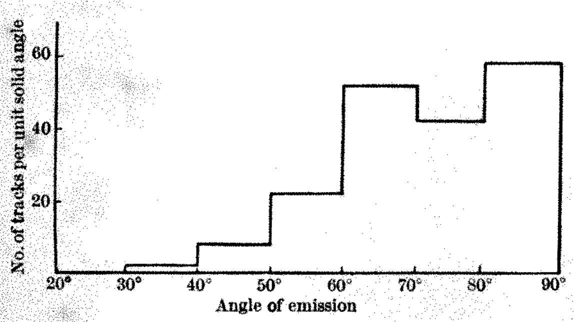

Fig. 3

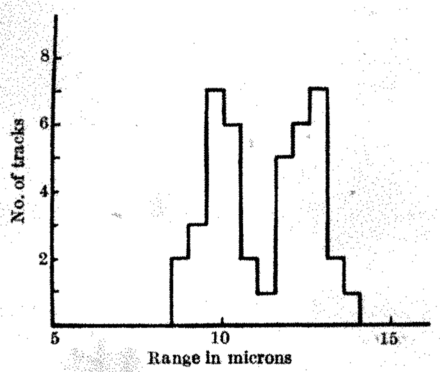

Fig. 4

ions but insensitive to protons. In cases where the emission of a third light particle was observed, measurements of the range of the particle and of the angle between its track and those of the heavy fragments were carried out. Typical examples of the tracks are shown in the photomicrographs, Fig. 1 *a*, *b*, *c*. The grain density in the light-particle tracks is consistent with the hypothesis that these particles are α-particles, although the possibility that they are nuclei of slightly greater mass cannot be excluded. It is, however, certain that the particles are not recoil nuclei projected by fission fragments in their passage through the emulsion, since the observed directions of emission are inconsistent with the momentum relations for such collision processes.

The range distribution of the light particles observed is shown in histogram form in Fig. 2; it shows that particles of all ranges from the lower limit of detection of 1·7 microns (2·8 mm. air equivalent) to a maximum in excess of 250 microns (45 cm. air equivalent) are present. A considerable number of particles fall into a short-range group; these particles had been detected previously in this Laboratory by coincidence counting methods[3]. The abundance of light particles of all ranges is 1 in 80 ± 4 fission events; for particles of range greater than 5 microns (equivalent to 8 mm. of air) it is 1 in 340 ± 30 fission events.

The angular distribution of the light-particle tracks has been determined, and is shown in Fig. 3, in which the number of tracks per unit solid angle is plotted against the angle between the direction of emission of the light particle and the fission fragment tracks. No significant difference between the angular distribution of the short-range and long-range particles has been detected. It is evident from Fig. 3 that the particles are emitted preferentially in directions nearly perpendicular to the fission fragment tracks.

Assuming that the third particle is emitted simultaneously with the two heavy fragments, its track defines the point of fission, and so the range distribution of the individual fission fragments in these events may be determined. The results of such range measurements give a distribution shown in Fig. 4, which refers to those events characterized by the emission of a long-range particle. The double peak of the distribution indicates that there is unequal division of mass in the modes of fission which produce light charged particles of high energy.

In the 25,000 fission events investigated, we have found no evidence of fission of the uranium nucleus into more than three charged particles.

We should like to thank Prof. N. Feather for much helpful advice. A more detailed account of the work will be published elsewhere.

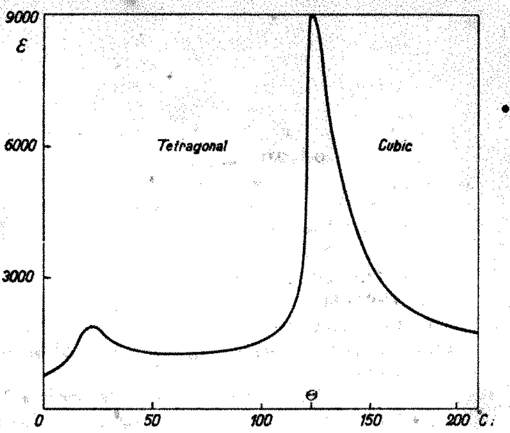
Effect of Temperature on the Permittivity of Barium Titanate

It is well known[1] that the dielectric behaviour of barium titanate and some mixed crystals of it with related compounds is quite different from most other materials (see accompanying illustration). At a certain temperature, θ, a very high value of the permittivity ε is found. On the left side of the peak, ε decreases with decreasing temperature though still some secondary maxima are found; on the high-temperature side of the peak, however, ε decreases monotonically.

According to Rooksby[2] and Miss Megaw[3], barium titanate shows an ideal cubic perovskite structure at temperatures above θ. In the neighbourhood of θ, a tetragonal distortion of the lattice takes place, persisting down to liquid–air temperatures.

In order to explain the permittivity–temperature curves in the cubic region, it has been assumed[4] that in these lattices permanent dipoles occur. At first sight this may seem reasonable, because for barium and lead titanates the ratio of the ionic distances is such as to allow a rather large space for the titanium ion. From electrostatic considerations it might be expected that the potential curve of the titanium ion would not show one minimum situated in the



DIELECTRIC CONSTANT OF BARIUM TITANATE AS A FUNCTION OF TEMPERATURE MEASURED WITH A.C. VOLTAGE OF 100 V./CM. AND A FREQUENCY OF 5 KC./S.

centre of the TiO_6 octahedron but several excentric positions of minimal energy.

By plotting $\frac{\varepsilon - 1}{\varepsilon + 2}$ against temperature in the cubic region, Rushman[4] derived a dipole moment of about $0{\cdot}1 \times 10^{-18}$ E.S.U., which seemed to be a plausible value in comparison with the magnitude of the dipole which is estimated from the free space available for the titanium ion.

In these calculations, however, the effect of thermal expansion has been neglected. This effect will cause a decrease of permittivity with increasing temperature.

We have tried to describe the dielectric properties by means of the Clausius–Mosotti formula :

$$\frac{\varepsilon - 1}{\varepsilon + 2} = \frac{4\pi}{3} n\alpha, \qquad (1)$$

where n is number of unit cells per cm.^{3} ; α is polarizability per unit cell (in the general case α may contain a dipole contribution).

From (1) the following expression for the temperature coefficient (T.C.) can be derived :

$$\text{T.C.} \equiv \frac{1}{\varepsilon}\frac{d\varepsilon}{dT} = \frac{(\varepsilon - 1)(\varepsilon + 2)}{\varepsilon}\left\{-\beta + \frac{1}{3}\frac{1}{\alpha}\frac{d\alpha}{dT}\right\}, \quad (2)$$

where β is coefficient of linear expansion.

For TiO_2 (rutile) we found at room temperature experimentally a temperature coefficient of $-8{\cdot}3 \times 10^{-4}$, whereas the term $-\beta\,\frac{(\varepsilon - 1)(\varepsilon + 2)}{\varepsilon}$ calculated from β- and ε-measurements was found to be also $-8{\cdot}3 \times 10^{-4}$. From this we may conclude that here the temperature-dependency of α may be neglected.

In the case of high values of ε, (2) may be approximated by

$$\frac{1}{\varepsilon}\frac{d\varepsilon}{dT} = -\beta\varepsilon. \qquad (3)$$

From this it follows that

$$\frac{1}{\varepsilon} = \beta(T - C), \qquad (4)$$

which is exactly the hyperbolic law found by Rushman[4] in the cubic region of barium titanate (C is a temperature only slightly different from θ).

When the temperature curve for rutile and for some titanates in the cubic region is derived by means of formula (4), we find that the experimental data can be represented in a quite accurate way by formulæ of this type.

$$\begin{array}{ll}
TiO_2 & \frac{1}{\varepsilon} = \left\{0{\cdot}73 \times 10^{-5}\,(T + 907)\right\} \\
BaTiO_3 & \frac{1}{\varepsilon} = \left\{0{\cdot}98 \times 10^{-5}\,(T - 393)\right\} \\
(Ba\ 0{\cdot}70,\ Sr\ 0{\cdot}30)\ TiO_3 & \frac{1}{\varepsilon} = \left\{1{\cdot}07 \times 10^{-5}\,(T - 306)\right\} \\
(Ba\ 0{\cdot}40,\ Sr\ 0{\cdot}60)\ TiO_3 & \frac{1}{\varepsilon} = \left\{0{\cdot}90 \times 10^{-5}\,(T - 188)\right\} \\
Sr\ TiO_3 & \frac{1}{\varepsilon} = \left\{0{\cdot}96^5 \times 10^{-5}\,(T + 65)\right\}
\end{array}$$

For β we found by expansion measurements

TiO_2	$0{\cdot}73 \times 10^{-5}$
$BaTiO_3$	$0{\cdot}95 \times 10^{-5}$
$(Ba\ 0{\cdot}65,\ Sr\ 0{\cdot}35)\ TiO_3$	$0{\cdot}98^5 \times 10^{-5}$

From this we may conclude that the α of these titanates is constant for temperatures above θ. The temperature coefficient appears to be a consequence of the variation of density only.

Hence we believe that in the temperature region of cubic structures there is no permanent dipole moment ; whereas in the tetragonal region where 'ferro-electric' phenomena (dependence on field strength, hysteresis) are observed, the assumption of such dipoles seems to be quite plausible.

A fuller account of these considerations will be published shortly.

Electrical Conductivity in Insulating Amorphous Solids

WE have carried out some preliminary experiments to find the current-voltage stress characteristics of soda-lime glass, this being taken as an example of an amorphous solid having the properties of an electrical insulator.

The conductivity stress relationships have been predicted theoretically by Dr. Fröhlich[1], and our conclusions would seem to be in agreement with his theory. Some previous workers[2] in the field of dielectric conductivity have restricted themselves to D.C. measurements of the conductivity, and their results have often indicated changes of conductivity with time (often over a period of minutes or hours). Other workers[3] have investigated the so-called 'breakdown voltage stress' and analysed their results statistically, thus producing valuable practical information.

We felt that there was considerable uncertainty in the definition of 'breakdown-stress', particularly as many workers insist on applying their stress for a definite time before 'breakdown' occurs. Believing that this breakdown may be either purely of an electrical nature, or purely of a mechanical nature due to change of state arising from thermal heating effects, we are investigating the conductivity of insulators at voltage stresses up to the 'breakdown' stress. It is thought that this will yield information

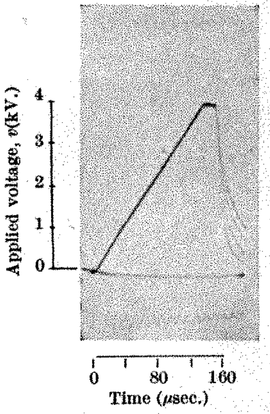

Fig. 1 *a*. APPLIED VOLTAGE WAVE-FORMS

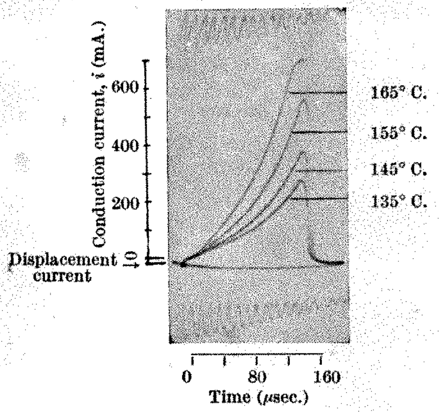

Fig. 1 *b*. CURRENT WAVE-FORMS

on the actual behaviour of conductivity before 'breakdown'.

In brief, our method was as follows. A small thin glass bulb blown at the end of a tube was filled with, and inserted in, mercury, thus providing two mercury electrodes. A single pulse the magnitude of which increased linearly with time for approximately 150 μsec. from zero up to 4 kV. max. was applied between the electrodes, and the sum of the displacement and conduction currents through the thin insulating bulb recorded at different temperatures by means of a recording cathode-ray oscillograph (see Figs. 1*a* and *b*). It will be seen that the conductivity increased with temperature, as was to be expected from the well-known law

$$\sigma = \sigma_0 \exp\left(-W/kT\right) \qquad (1)$$

applicable to low field strengths. The conductivity, however, also increases with applied field strength, the theoretical law[1] being

$$\log_e \frac{\sigma}{\sigma_0} = \frac{V_1}{\Delta V} \cdot \frac{1}{e} \cdot \frac{F^2}{F^{*2}} \qquad (F \ll F^*), \qquad (2)$$

where F^* is critical field strength, F is applied field strength, σ is conductivity, V_1, ΔV, σ_0 are constants, e is 2·73. Our practical arrangement did not allow us to determine σ or F absolutely, but gave figures proportional to each.

If the theoretical law (Equation 2) is true, then we expect to find

$$\log \frac{i}{v} = K_1 + K_2 v^2, \qquad (3)$$

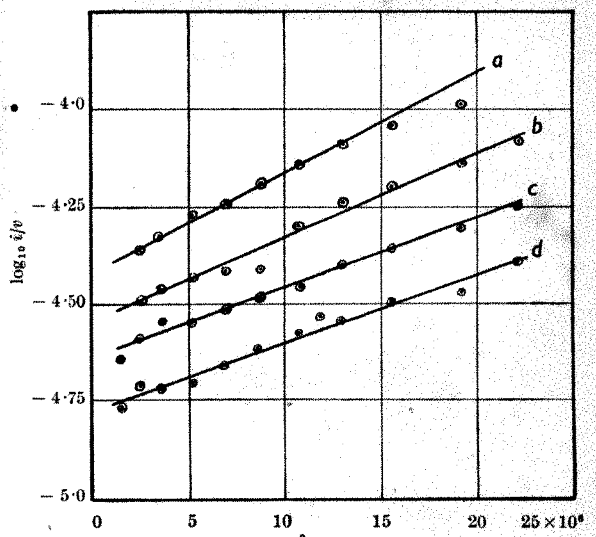

Fig. 2. (*a*) 165° C.; (*b*) 155° C.; (*c*) 145° C.; (*d*) 135° C.

where i is instantaneous current, v is instantaneous applied voltage, K_1, K_2 are constants.

$\text{Log}_{10}\, i/v$ is plotted against v^2 in Fig. 2, and a straight line results, apparently verifying the square law relationship in F of Equation 2.

It is believed that this method of approach to the problem of electrical conductivity in solids is new, and that it has a great advantage over previous methods of measuring conductivity at large field strengths, as it almost entirely eliminates complications due to heat generated in the specimen by the conduction current.

We are indebted to Dr. H. Fröhlich of the University of Bristol for a helpful discussion, and to Dr. D. M. Robinson for suggesting the investigation and the experimental method.

Detectability of the Negative Proton

IT is customary to employ Dirac's equation to describe the proton, which is known to have spin ½. Therefore, it is to be expected that the negative proton should exist, though this particle has never been detected experimentally. In a study of the production and annihilation of negative protons[1], it was shown that it is not surprising that the particle has not been observed; but it was suggested that it could be observed, if certain cosmic ray experiments were improved. The calculations were based on the resolution of the field of a fast nucleon into a spectrum of mesons by the method of v. Weizsäcker[2] and E. J. Williams[3], and for simplicity account was taken only of the pseudoscalar mesons.

The problem has again been studied[4], account being taken not only of the pseudoscalar mesons of the Weizsäcker spectrum but also of its longitudinal and transverse mesons, in accordance with the Møller–Rosenfeld form of the meson theory[5]. It is found that the rate of production of negative protons should be three or four times smaller than that given in the earlier paper. However, it must be noted that all the numerical results are probably upper limits and should perhaps be two to five times smaller. In fact, the densities of the mesons in the Weizsäcker spectrum depend rather sensitively on the value of the lower limit of the impact parameter, which has been taken to be the Compton wave-length of the nucleon $\hbar/Mc$, but which in reality may be somewhat larger[4].

When the negative proton has been produced by the collision of a cosmic ray meson and a nucleon, it may escape detection by producing mesons and so losing its negative electrical charge. It appears from cosmic ray experiments that the cross-section φ for meson production by a proton, or negative proton, is at least $4\cdot6 \times 10^{-26}$ cm.², that is $(\hbar/\mu c)^2$, where μ is the mass of the meson[7]. The corresponding mean free path in nuclear matter is

$$\tau = 1/N\varphi,$$

where N is the number of nucleons the total volume of which is equal to 1 cm.³. Taking the radius of the lead nucleus to be $1\cdot1 \times 10^{-12}$ cm., one obtains

$$N = \frac{3 \times 207 \times 10^{36}}{4\pi \times 1\cdot1^3}, \text{ so that } \tau = 6 \times 10^{-13} \text{ cm.}$$

Hence the maximum value of the mean free path of the negative proton in nuclear matter is about four times the average distance between the nucleons in a nucleus.

Assuming that the mean free path is approximately equal to the average distance between two nuclear particles, one may estimate what is the probability that a negative proton will escape from the nucleus where it has been formed without losing its negative charge. It will lose its charge if it collides with a nucleon, and that will certainly happen unless it has been produced in the surface layer. However, even in the case of a large nucleus such as lead, most of the nucleons are in this layer. If the negative proton has been produced on the surface, then there is roughly a 50 per cent chance that it will not collide with a nucleon. Thus the process of meson production in the nucleus will scarcely reduce the probability of detecting the negative proton by more than a factor 3.

When a negative proton has emerged from the nucleus, it may be lost to observation by producing mesons in the surrounding material. Its mean free path is less than 4 cm. of lead, which corresponds approximately to one thirtieth of the atmosphere. So a negative proton formed by the collision of a cosmic ray meson and a nucleon in the atmosphere will not come down to sea-level unless it has been produced in the lowest one thirtieth of the atmosphere. This considerably reduces the chance of observing the negative proton in sea-level cosmic radiation[6]; hence with the present experimental technique it is very unlikely that the particle could be detected by examining the charge of the particles which cause the heavy tracks in cloud-chamber photographs.

If one studies the production of negative protons by the passage of mesons with energy greater than 4×10^9 eV. through a lead plate of 1 cm. thickness and allows for the loss by meson production, one finds that at least one hundred thousand mesons would have to penetrate before one negative proton would be formed. Thus a long series of experiments would now be required to observe the particle; though, when the present experimental methods have been improved, it may not be too difficult to detect the negative proton.

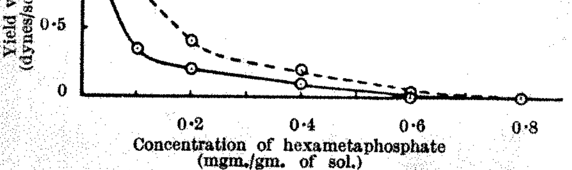
Effect of Sodium Hexametaphosphate on the Yield Value and Viscosity of a Hydrogen Bentonite Suspension

Phosphates, especially the sodium hexametaphosphate, are now widely applied for the treatment of drilling muds used in the rotary drilling of oil-wells[1]. Some papers dealing from the colloid chemical point of view with the action of phosphates on clay suspensions have recently been published[2]. A majority of investigators appears to have expressed the results of their measurements in terms of apparent viscosity and to have paid insufficient attention to the progress of the reaction. We have tried in our work to overcome these objections, and have obtained some results which seem to need further explanation. Results of detailed investigations will be published elsewhere; but the preliminary observations appear to be sufficiently interesting to be communicated here.

We have used a rotary viscometer designed by Mukherjee and Sen Gupta[3]. Various quantities of a sodium hexametaphosphate solution were added to a 12 per cent aged hydrogen bentonite suspension, prepared by electrodialysis, and the requisite quantities of water were added to make the suspensions 10 per cent in every case. Viscometric measurements were made using the suspensions just after addition of the phosphate, and then at intervals up to a period of twenty days. 'Initial' and 'final' yield values and viscosities (obtained from graphical extrapolation) are shown in the accompanying figure.



Full curve, immediate (initial); broken curve, after 20 days (final)

It appears from the graph that the phosphate has a greater effect in reducing the yield value than the viscosity. The more important observation which was not quite expected is that, while the viscosity increases on standing, tending to reach the original figure, the yield value for the higher concentrations of phosphate (0·6–0·8 per cent) does not increase on standing up to a period of twenty days. The results cannot be explained by assuming that the phosphate ion is fixed by aluminium or enters the clay complex; for while this would account for the reversion of viscosity to the original figure, the constancy of the yield value seems to be at variance with this hypothesis.

We acknowledge our indebtedness to Mr. K. D. Bhabock for his collaboration in the experimental work.

Theory of Molecular Coupling in Polar Liquids

In 1939 I published[1] a general outline of the theory of the phenomena of molecular orientation in polar liquids. During the War I have generalized and worked out this theory in more detail.

Four effects of molecular orientation have been considered: (i) dielectric polarization, (ii) dielectric saturation in a strong electric field[2], (iii) electric birefringence (Kerr effect), and (iv) magnetic birefringence (Cotton – Mouton effect). The only liquid in which all these effects have been thoroughly examined is nitrobenzene. Fig. 1 represents the experimental results for nitrobenzene and its solutions in non-polar solvent (benzene). R, R_S, R_K and R_{CM} are 'reducing factors' corresponding to these effects respectively. Reducing factors are defined as the ratio of a 'molar constant', for example, molar polarization $P^{\text{dip}} = \dfrac{4\pi N \mu^2}{9\,kT}$, calculated for a liquid or its solution, to the same 'molar constant' (for example, $P^{\text{dip}}_{\text{gas}}$), determined for the same substance in the gaseous state. The calculation is based on the assumption of the validity of the Lorentz formula for the local field.

I have also applied the Onsager field[3] to the calculation of molar constants for these four effects from experimental data. The corresponding reducing factors are plotted in Fig. 2 against the number of dipole molecules per cm.^{3} of solution, as before. The curves show a quite different type of variation from that of the Lorentz field. First, the 'molar constants' are not constant, in disagreement with what might be expected on the basis of Onsager's theory. Further, the increase of R and R_K observed for higher concentrations indicates that a new kind of molecular coupling (kind III) must be considered to explain this behaviour.

In the paper quoted above[1], I assumed two kinds of coupling forces. The coupling of kind I is that of Fowler – Debye[4,5] due to the combined action of a great number of surrounding molecules. The coupling of kind II consists in the transitory formation of unstable and non-rigid pairs with the nearest neighbouring molecule. The theory based on these assumptions gives only a qualitative agreement with the Lorentz curves represented in Fig. 1. It explains in particular the change of sign of R_S and the fact that R_{CM} is greater than unity[6]. It is impossible, however, to obtain a quantitative agreement between the theory and the full set of Lorentz curves given in Fig. 1.

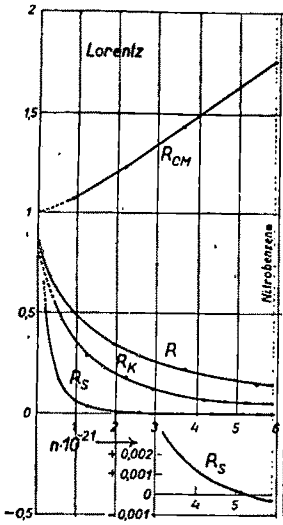

Fig. 1

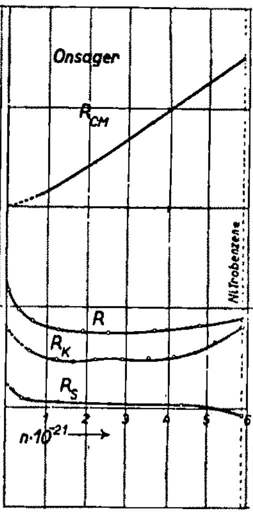

Fig. 2

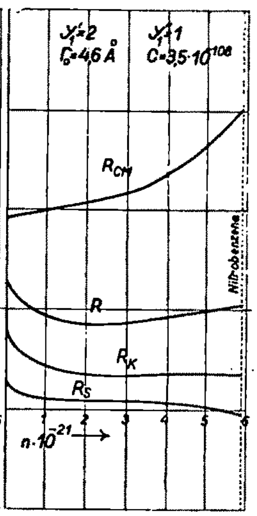

Fig. 3

Fig. 1. Reducing factors calculated from experimental data using the Lorentz local field

Fig. 2. Reducing factors calculated from experimental data using the Onsager local field

Fig. 3. Theoretical reducing factors calculated assuming the existence of three kinds of coupling forces. To be compared with Fig. 2

I was able to obtain a reasonable quantitative agreement between theory and experiment using the Onsager local field and assuming in addition the above-mentioned coupling of kind III. This coupling results from the mutual interaction of the transitory quasi-antiparallel pairs formed by the coupling of kind II. The total electric moment is thus increased.

It is significant that the agreement between the theory and experiment is assured for all four phenomena considered by one set of four constants common to all the formulæ. The theoretical curves are shown in Fig. 3, in which the numerical values of the constants are also given. Comparing the experimental curves (calculated on the basis of Onsager's local field, Fig. 2) with the theoretical ones (Fig. 3), it can be seen that many characteristic features of the experimental curves are well reproduced by the theory.

Recently, I calculated on the same assumptions the lowering of the freezing point of dilute solutions of polar liquids in non-polar solvents. Agreement with the experimental data has been obtained without introducing any new constant.

A full account of this work will be published elsewhere.

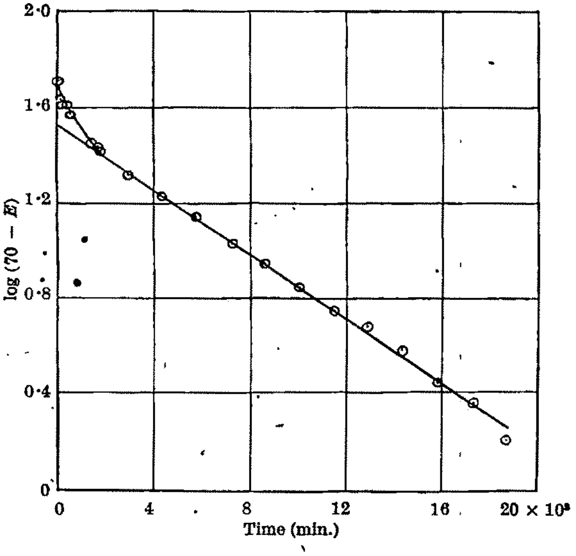
Structure of the Keratin Molecule

WHEN wool fibres of uniform cross-sectional area are stretched extremely slowly in saturated air at 18° C., they break at 70 per cent extension[1]. Confined in its early stages to the amorphous regions of the fibre, extension occurs by the transformation of the crystalline phase from the α- to the β-configuration at extensions above about 25 per cent[2]. It has been found possible to disentangle these two processes, and obtain a closer insight into the α-β-transformation process, by studying the extension of wool fibres under constant *stress*[3] in saturated air at low temperatures. Under a stress of $6\cdot89 \times 10^{5}$ gm./cm.^{2} at 21° C., for example, the immediate extension of the fibre (3 minutes after the application of stress) was 19·4 per cent, rising to 30·2 per cent after 300 minutes and 68·4 per cent after 18,682 minutes. As might be expected, there is an exponential approach to the limiting extension of 70 per cent, as shown in the accompanying figure, where log $(70 - E)$ is plotted against time.

Since the linear relationship is not obeyed in the early stages, where extension occurs mainly in the amorphous phase, and since extrapolation of the line indicates an initial extension of 35·6 per cent, it is clear that extension of the fibre over the period from 1 to 13 days is due to slow unfolding of the molecules of α-keratin in the crystalline phase. The slope (k) of the line in the figure is a measure of the rate of unfolding, and by determining k at different temperatures with wool fibres under various stresses, the activation energy associated with the α-β-transformation can be calculated.



Under a stress of $6\cdot89 \times 10^{5}$ gm./cm.^{2} at 21° C. and 13° C., the values of k were $6\cdot76 \times 10^{-5}$ and $2\cdot65 \times 10^{-5}$, respectively, corresponding to an activation energy of about 20 kcal. This, in turn, agrees with Astbury's conception[4] of the nature of the intramolecular fold in α-keratin, for the opening of each fold involves the breakdown of three hydrogen bonds between —CO— and —NH— groups.

Determinations of the rate of extension of wool fibres under constant stress thus provide a simple and attractive means of studying the structure and reactivity of α-keratin, and the above experiments are now being extended to wool and other fibres under a wide variety of conditions.

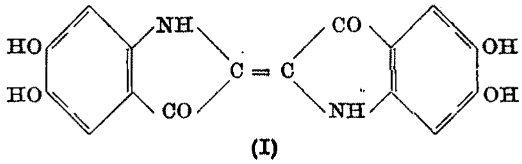
Constitution of Melanin

IT has been suggested recently[1] that 5 : 6 : 5′ : 6′-tetrahydroxy-indigo (I), or a quinone or semi-quinone derived from it, is an important constituent of melanin, the black pigment produced by the oxidation of tyrosine and 3 : 4-dihydroxyphenylalanine[2].



(I)

It was therefore of interest to synthesize the tetrahydroxyindigo by an unambiguous route and to compare its properties with those of melanin. An attempt to synthesize the compound was made by Hayduck[3], who unsuccessfully tried to demethylate a product which he considered to be 5 : 6 : 5′ : 6′-tetramethoxyindigo ; however, he showed later[4] that the tetramethoxy compound in question was, in fact, the 6 : 7 : 6′ : 7′ isomer. Clemo and Weiss (*loc. cit.*) attempted to remove the methylene groups from piperonal-indigo; but this procedure was also unsuccessful, only products insoluble in aqueous alkali being obtained.

The starting material used in the present synthesis was 6-nitroprotocatechuic aldehyde, which was prepared by Parijs[5] by the action of fuming nitric acid on 6-nitropiperonal diacetate in acetic anhydride solution. On repetition of this work it was found that the yields obtained were much smaller than those described, and the process could not be adapted for larger scale preparation. 6-Nitro-piperonal was found to be remarkably resistant to demethylenation by the usual methods, but it was eventually found that the methylene group could be removed successfully by heating with an excess of pyridine hydrochloride to 160–170°, and this appears to be the only practicable method.

When the disodium salt of 6-nitroprotocatechuic aldehyde was treated with two molecules of chloromethyl ether in benzene, 3 : 4-bis-(methoxymethoxy)-6-nitrobenzaldehyde was obtained, and this compound on treatment with acetone and alkali gave 5 : 6 : 5′ : 6′-tetra(methoxymethoxy) indigo in good yield. Hydrolysis with dilute mineral acid then yielded the required tetrahydroxyindigo. The product was a greenish-black powder, slightly soluble in pyridine and nitrobenzene with a greenish-blue colour. It was readily soluble in aqueous sodium hydroxide giving an intense permanganate-violet solution, and was reprecipitated unchanged by addition of acid. Acetylation with acetic anhydride and pyridine gave the tetra-acetyl derivative which crystallized well from nitrobenzene. On reduction with sodium hydrosulphite and alkali a yellow vat was obtained, re-oxidizing readily in air to give a violet solution.

The tetrahydroxyindigo is thus quite different from melanin, which is slightly soluble in alkali with a greenish-brown colour. Furthermore, it is scarcely possible that melanin can be a quinone or semiquinone derived from tetrahydroxyindigo, since such a compound would undoubtedly be reduced by sodium hydrosulphite and alkali to the same leucocompound as that formed from the tetrahydroxyindigo itself: this latter is certainly not obtained from melanin, as the hydrosulphite vat from this substance does not re-oxidize to give the characteristic violet colour shown by alkaline solutions of the tetrahydroxyindigo.

Full details of this work will be published elsewhere in due course.

THE interesting method used successfully by Harley-Mason for demethylenation is similar to that worked out in Germany[1] during the War using pyridine hydrochloride for the demethylation of phenol ethers, which was unknown to us at the time of our work.

The conclusions reached in our paper were largely based on the determination of the oxidation equivalents by H. S. Raper. Accepting Raper's figures, the indigoid formulation suggests itself as the most likely one on the basis of our experiments and on the known behaviour of dihydroxyindole. As implied in our paper, and bearing in mind the marked instability of catechol compounds under biological *p*H conditions, it is very unlikely that the hydroxyl groups are present in the free state.

If, on the other hand, one admits higher oxidation figures than those given by Raper, then clearly there is the possibility of polymerization products of indigoid type, for example, with a dehydrotype as polymerizing unit.

Existence of Cupric Hexammino Sulphate

WHILE the hexammino compounds of the halides, nitrates and other salts of copper are well known, nothing seems to be on record regarding the existence of cupric hexammino sulphate. In recent communications, Dey and Bhattacharya[1] have described a new method for the isolation of cupric pentammino sulphate, from ammoniacal solutions of cupric sulphate. In other publications from this laboratory, Dey has recorded the results of the conductometric measurements of mixtures of cupric nitrate[2] or chloride[3], with ammonium hydroxide solutions, of various compositions. The conductometric curves gave breaks corresponding to three, four, five and six molecules of ammonia for one molecule of the copper salt, thus affording the evidence for the existence of tri-, tetra-, penta- and hexa-ammino cupric compounds. In the case of cupric ammino sulphates, however, the triammino compound is not found, whereas the three other compounds are formed. The changes in the extinction coefficients of mixtures have also been studied by means of a Nutting's spectrophotometer, and the results confirm those obtained by the electrical conductivity method. We thus find that these results indicate the definite existence of cupric hexammino sulphate, as well, in an ammoniacal solution of cupric sulphate.

I am indebted to Dr. A. K. Bhattacharya, head of the Department of Chemistry, University of Saugor, for his interest in this work.

Statistical Methods in Chemical Analyses

IT is well established that many of the distributions met in biological work approximate to the normal, and the modern developments of statistics are associated with this fact. Most of the techniques are dependent for their validity, to a greater or less extent, on the goodness of the normal equation as a description of the experimental distributions. Since there cannot be any *a priori* reasons for expecting distributions in chemical work to be normal, and there seems to have been very little investigation of the natures of the distributions actually occurring, application of methods which presume normality may be highly dangerous.

With the view of ascertaining whether such methods can be applied, I have carried out an investigation of a number of distributions arising in the course of analysing chemically a wide variety of the products of industry in the Chemical Inspection Department of the Ministry of Supply. The products included metals, alloys, 'pure' and 'commercial' chemicals, mixtures, etc., from thirty or forty different firms. Some 250 distributions, involving about 50,000 chemical analyses, have been examined. The analyses were of various kinds, such as determinations of impurities present as traces or in larger amounts, assays of substances both pure and crude, and measurements of characteristics, by chemical and physical methods, such as are ordinarily carried out in the control laboratories of chemical industry.

It was found that only 10–15 per cent of these distributions could, for practical purposes, be regarded as normal. The remainder were significantly non-normal. Some 15 per cent of the distributions were of the form of truncated normal curves. These may, of course, be treated as the tails of normal curves which can be fitted either (i) graphically, (ii) by Pearson's method of the moments about the stump, or (iii) by a least squares method which has been developed.

About 10 per cent of the distributions were symmetrical ($\beta_1 \doteqdot 0$) but showed leptokurtosis ($\beta_2 > 3$) to an appreciable extent, and the χ^2-test for the goodness of fit of a normal equation gave values of $P < 0{\cdot}01$. Thus they could not be described satisfactorily by equations of the normal form. Fitting of curves, such as Pearson's Type III, did not prove to be entirely satisfactory. A mathematical model, which is the sum of the products of two Poisson distributions, has been worked out, and it seems that distributions of this type may usefully be described by the equation

$$y_x = I_{|x|}(\sigma^2) \,.\, \exp(-\sigma^2),$$

in which $I_{|x|}(\sigma^2)$ is a Bessel function of the second kind.

Since $|x|$ is used, the curve is symmetrical about $x = 0$ and extends from $-\infty$ to $+\infty$. The integral is unity, and hence the expression may be used as a probability distribution.

The lower moments of this distribution are $\mu_2 = \sigma^2$; $\mu_3 = 0$; $\mu_4 = 3\sigma^4 + \sigma^2$, and the coefficients $\beta_1 = 0$ and $\beta_2 = 3 + \frac{1}{\sigma^2}$.

Since

$$\sigma_\sigma = \frac{\sigma}{\sqrt{2n}} \left(1 + \frac{\beta_2 - 3}{2}\right)^{1/2},$$

we have for the standard deviation of the standard deviation of this distribution

$$\sigma_\sigma = \frac{\sigma}{\sqrt{2n}} \left(1 + \frac{1}{2\sigma^2}\right)^{1/2}.$$

The expression in brackets differs from unity by more than five per cent when $\sigma^2 = 5$. Hence, for large samples, the usual expression for the standard deviation of the standard deviation cannot be used when $\sigma^2 < 5$. In the actual distributions studied, it has been found that the degree of leptokurtosis is considerably greater than this. The position in regard to small samples is being investigated.

Some 10 per cent of the distributions were truncated leptokurtic curves apparently derived from the above parent distribution.

About 20–25 per cent of the distributions were *J*-shaped. It has been found that many of these may usefully be described by an equation of the form

$$y_x = \frac{1}{\sqrt{2\pi . a x}} \left(\frac{\bar{x}}{x}\right)^{ax} . \exp a\,(x - \bar{x}),$$

the parameters of which can readily be calculated.

Some 20–25 per cent were skewed. Some of these may be treated by logarithmic or other transformations of the variable, but these methods are not entirely successful. A promising approach to a generalized equation for this type of curve is now being explored. This equation is of the form

$$y_x = \left(\frac{\sigma^2 + \bar{x}}{\sigma^2 - \bar{x}}\right)^{x/2} \cdot I_{|x|}\left(\sqrt{\sigma^4 - \bar{x}^2}\right) . \exp(-\sigma^2),$$

of which the lower moments are

$$\mu_2 = \sigma^2;\ \mu_3 = \bar{x};\ \mu_4 = 3\sigma^4 + \sigma^2.$$

The remainder of the distributions were irregular. A few were bi-modal and have yielded to analysis into the sum of two normal distributions.

From the data under consideration it has been possible to associate certain types of chemical data with the above different kinds of distribution.

The principal conclusions of this investigation are: (1) great caution must be exercised in applying the ordinary simple statistical methods to the data of chemical analysis; (ii) many of the distributions depart radically from the normal and are possibly more correctly to be regarded as forms of 'rare occurrence' distributions; (iii) the continuous nature of the variable is, in many cases, probably superficial, and it should, more correctly, be regarded as a discontinuous variable.

It is hoped shortly to publish this work in full elsewhere. I wish to express my appreciation to Prof. H. Levy and Prof. H. V. A. Briscoe for advice and encouragement, and to the Chief Scientist, Ministry of Supply, for permission to publish the work.

Transference of Vitamin D from the Female Rat to Her Young

No report has been found of the ability of the rat to transfer ingested vitamin D to the milk. The ability to do this is known to be limited in the human being[1,2,3,4], in the cow[5,6] and in the ewe[7]. An accidental and most unfortunate experience in this laboratory has provided a certain amount of information on the transmission of vitamin D from the diet to the milk of the rat.

The diet of the stock colony of rats[8] contains 10 per cent of full-cream dried milk powder. Litters intended for vitamin D tests are weaned at 21–23 days of age and fed on the stock diet until they are 55–65 gm. in weight, that is, for about ten days. If they are then given the Steenbock rachitogenic diet (2,965)[9] for a preparatory period of three weeks, they develop a severe degree of rickets and are suitable for use in determinations of vitamin D. A further period of ten days on the same diet together with a small dose of the standard or vitamin-containing substance results in the formation of a line of healing in the metaphyses of the ulnæ and radii with well-defined areas of uncalcified cartilage above and below it.

In August 1945 the healing as evidenced in the 'line test' gradually became very high, and by the end of September the bones showed very little signs of development of rickets after four and a half weeks on the rachitogenic diet. As short periods of apparent inability to produce rickets had previously been encountered, possible causes and methods of counteraction were explored with negative results. As the rats were kept during this period in a basement room illuminated solely by artificial light, the effect of excessive daylight suggested by previous experience to be the most probable cause of trouble was ruled out. The fresh cow's milk and liver were withheld from the diet of the stock colony, but with no apparent effect on the rachitic condition of the young when given the rachitogenic diet. In fact, it was observed that rats fed on the rachitogenic diet grew well and showed obvious signs of well-being. Moreover, in place of the usual seasonal drop in the number of litters produced by the colony in the later months of the year, the reproduction-rate was well maintained. At the end of December it was discovered with dismay that the dried milk used in making the stock diets for the breeding colony had been fortified by the producers with vitamin D. Deliveries in August, September and October were acknowledged to have been fortified; earlier ones were not determined. Assuming the vitamin D content of the milk to be 10 I.U. per gm. as now claimed for all 'National dried milk', an animal consuming 15 gm. of stock diet daily would thus be receiving about 15 I.U. of vitamin D a day.

The fortified milk was, of course, replaced by unfortified at the beginning of January 1946. The reappearance of rickets in young rats fed on the rachitogenic diet was followed by putting on fresh litters each week and examining some rats of each, week by week for six weeks, by the 'line test' technique. A mild degree of rickets began to develop in the young rats about the end of February, and the rachitic condition gradually became more and more severe until at the beginning of May it was severe enough to use the rats for vitamin D determinations after the usual three weeks preparatory period. During the later part of this long time of examining 'no dose' rats, a few cases of apparently spontaneous healing were observed; but on investigation it was found that the rats in which it occurred had eaten the greater part of one of their number while they had been housed all together in one cage. The healing in these rats may have been brought about by the ingestion of residual vitamin D in the eaten rat or of part of its skeleton, which might have been enough to upset the Ca : P ratio of the diet and bring about healing independently of the presence of vitamin D.

It might have been expected that, as soon as unfortified dried milk was again given to the colony, the young rats would develop the usual intensity of rickets when given the rachitogenic diet. They would surely have done so if the source of their vitamin D had been only the stock diet they had eaten between weaning and receiving the rachitogenic diet. However, successive litters of young rats, taken from stock week by week and prepared as described, developed no rickets at first, and only as time went on developed at first a mild degree of rickets, then a more severe condition, and finally after about four months a state of rickets comparable with that we had previously produced by the same treatment. This indicated clearly that the young rats must have obtained supplies of the vitamin from the doe, either via the placenta or from the milk during lactation, and stored it somewhere for use as needed. The severity of the rickets developed in the different litters after four months of unfortified dried milk in the stock diet did not vary much, and we were able to proceed with the determination of vitamin D in the usual way.

It is tempting to try to estimate the adult doe's need of vitamin D from this experiment, but there are too many unknown factors in it. The amount of vitamin D taken in by the does during the four months when the diet contained fortified dried milk was probably more than 2,130 I.U. (that is, 15 I.U. a day for 142 days from the dried milk, and an unknown amount, though small, from the rest of the diet). But there is no indication of how much of this was absorbed or stored or used up by the rat while she was being fed on the enriched diet. She certainly had stored some of it, but there is no indication of what her store was when unfortified dried milk was again given in the diet. We only know that the store was exhausted within a further four months, during which each doe probably had two litters and gave to her young decreasing amounts of vitamin D as time went on. That the doe would probably benefit by receiving more vitamin D than the stock diet usually contains is indicated by the fact already mentioned that the breeding of the colony (as evidenced by the number of litters born) was higher during the winter months of 1945–46 than in any previous winter of the colony's existence.

Heat Treatment and the Biological Value of Soya-bean Protein

FROM the observations of other workers[1-12], it appears that the increase in biological value in heat-treated soya-bean may be due to three reasons: (1) heat treatment increases the availability of cysteine and methionine due to some change in the structure of the protein; (2) proteolytic inhibitor is inactivated by heat treatment; (3) any toxic factor which may be present other than the inhibitor is destroyed by heat.

The present study was conducted to see whether heat treatment is essential for improving the biological value of soya protein. For this purpose pure glycinin was separated from defatted soya-bean and its nutritive value compared to that of raw bean. The extraction was carried out at pH 7·0 with 6 per cent sodium chloride, and the aqueous extract was dialysed and precipitated further by bringing down the reaction to pH 4·2. The precipitated glycinin was centrifuged out. The biological value of glycinin and the proteins in raw and autoclaved soya-bean were compared by determining the growth in young albino rats over a period of eight weeks. The protein was fed at 10 per cent level. The results obtained are as follows:

Source of protein	Protein consumed (gm.)	Gain in weight (gm.)	Gain in weight (gm.) per gm. protein consumed
Raw soya-bean	29·1	22·6	0·78
Glycinin	31·5	48·8	1·55
Autoclaved soya-bean (15 lb. for 1 hr.)	30·6	44·7	1·46

The results show that heat is not essential for enhancing the nutritive value of the protein in raw soya-bean as the glycinin is more effective in promoting growth than autoclaved soya-bean.

The proteolytic inhibitor and also any toxic factor which may be present in raw soya-bean are eliminated in the process of preparing glycinin. This is supported by the observation that the acid extract of soya-bean retards the growth of rats provided with a well-balanced diet.

Further studies are in progress to determine the nature and mechanism of action of the factors present in the extract.

Our thanks are due to Prof. V. Subrahmanyan for his interest in the work.

Solvent-treated Cellulose Acetate as the Stationary Phase in Partition Chromatography

Silica gel and cellulose have a wide application as stationary aqueous adsorbents in partition chromatography, the moving phase being an organic solvent. For many purposes a stationary organic phase is desirable, and the use of solvent-treated organic polymers to serve as supporting media for organic solvent phases has, therefore, been investigated.

Cellulose acetate, as ½-in. staple filaments, when treated with *n*-butyl alcohol at 50° C. for thirty minutes, cooled, filtered, pressed and washed with saline to remove excess solvent, serves as a stationary organic solvent phase. 50 gm. of this material, packed tightly in a column, was sufficient adsorbent to extract exhaustively cresol and benzoic acid from 2 litres of an aqueous 0·1 per cent cresol solution, saturated at room temperature with benzoic acid, and with addition of sodium chloride. The extracted organic substances could be eluted with aqueous alkaline eluents or by a suitable organic solvent such as ether.

A. E. Aréa Leão *et al.*[1], in the extraction of penicillin from culture media filtrates, used a suspension of "solvent-activated cellulose acetate" prepared by shaking an aqueous suspension of cellulose acetate with addition of a small proportion of suitable solvent, for example, chloroform. A chromatographic method was not used by them, and it is possible that the new technique described might prove to be an improvement on the usual solvent extraction procedure.

In general, suitable adsorbents may be prepared by treating the polymer with a solvent swelling agent at a temperature just below that required to cause aggregation of the swollen polymer particles. Cellulose acetate may be regarded as the prototype of a wide range of polymers that could be utilized in the manner described. W. Coltof[2] may be consulted for comprehensive data on the effect of solvents on cellulose acetate. A wide industrial application of this technique to solvent-water partitions is obvious.

I wish to thank British Celanese, Ltd., for generous gifts of polymers used in this department, and for information.

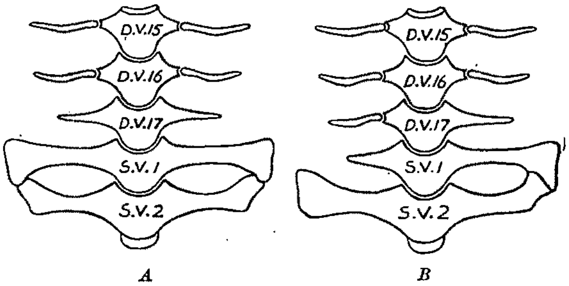
Sacral Ribs of Lacertilia

Some authors consider the lateral processes of sacral vertebræ in Lacertilia to be fused sacral ribs. Others deny this view and consider them to be nothing but well-developed transverse processes. While investigating the vertebral column of several individuals of the lizard, *Agama stellio*, I found one of them which supports the first view.



Agama stellio. Ventral view of the last three dorsal vertebræ (*D.V.* 15–17) and two sacral vertebræ (*S.V.* 1 and 2) of two different individuals

In *Agama stellio* the last dorsal vertebra possesses a pair of ribs which are completely fused with the centrum. There are two sacral vertebræ, each having a pair of well-developed lateral processes (Fig. 1 *A*). But in this particular individual, the last dorsal vertebra possesses two ribs, one of which is movably articulating with the centrum as all other preceding ribs do, while the other is completely fused with the centrum. The first sacral vertebra possesses two processes. The process of the right side is short, weakly developed and quite similar to the fused rib of the last dorsal vertebra referred to above. The process of the left side, on the other hand, is long, well-developed and resembles the processes of ordinary sacral vertebræ (Fig. 1 *B*). The right process of the first sacral vertebra can be easily homologized with the fused rib of the last dorsal vertebra, and the same is, then, true for the left process.

Therefore, the lateral processes of the sacral vertebræ of Lacertilia should be considered as sacral ribs which have fused with the centra of their vertebræ, and which have become greatly enlarged so as to perform the important function of supporting the pelvic girdle.

ASPECTS OF STRUCTURAL ENGINEERING

THE Bossom Gift Lecture for the current session, forming part of the programme of public lectures arranged by the Chadwick Trust, was delivered on November 26, 1946, at the Institution of Structural Engineers by this year's president of that body, Prof. H. J. Collins, Chadwick professor of engineering at University College, London. Under the title of "Some Aspects of Structural Engineering", Prof. Collins dealt broadly with the post-war building situation in Britain, with special reference to the report of the mission (on which Sir Alfred Bossom, who presided at the meeting, had served) which visited the United States of America in 1943, to the present policy of the Government on housing, and to the 'avalanche of paper' in the form of building studies, codes, standard specifications and revised regulations with which those who design and construct in these days are expected to comply. Having but recently resumed civilian duties after five years of active service in the Royal Engineers, Prof. Collins chose to refer by question rather than by answer to certain aspects of building and constructional engineering which marked the contrast between post-war and pre-war years.

Prof. Collins said that six non-constructive, indeed extremely destructive, years had brought the urgency of the need for building to a tremendous pitch, intensified by the general desire that social conditions should in the process be improved. Domestic housing is undoubtedly of the first importance ; it is necessary to employ as economically as possible both labour and material, and to devise substitutes for all materials which are not indigenous. Types of construction other than housing are also urgently needed. When work on these is resumed :

What will be the effect, on the progress of construction, of uncertainties both as to construction dates and as to the loads and stresses which will then be permissible ?

The economical use of materials is a measure of the skill of the engineer, but it takes from five to ten years to train a civil engineer, and none was being trained during the last three years of the War. It is therefore more than ever necessary to keep the knowledge of trained engineers up to date.

Are the results of advances in research being made readily available to the engineer ?

The supreme achievement in structural design is to attain simplicity approaching functional perfection. Under State control, the tendency might well be away from simplicity, but the attempt might nevertheless be made to overcome the shortage of engineers by standardizing methods of design. To control design by legislation must tend to change its governing principle from individual initiative and considered thought to rampant empiricism, and so put an end to scientific progress.

How far can standardization be carried without tending to kill initiative ? Should the establishment of such standards as might be necessary be made the responsibility, not of a Government department, but of the appropriate engineering professional institution ?

Ruskin showed that ancient building was often made wonderful by the marriage of science and art. Is the light of the Seven Lamps of Architecture so dim to-day, asked Prof. Collins, as to need the further illumination of some 174 building studies, codes and standards ?

Can studies, codes and regulations do away with the need for independent architects and for properly qualified structural engineers ?

A national policy governing the design and construction of buildings must be based on one of two alternatives : either it might allow any person to call himself an engineer, control him by regulations, and maintain conformity to these by a system of inspectors : or it might restrict the making of designs to selected persons of proved competence, and insist that such persons be qualified by institutional examination and/or by registration. Hitherto, standards of qualification for inspectors and systems of inspection in different parts of the country have varied considerably.

Could we accept as sound a national uniform set of building regulations ? Would registration act more for the national good or for the benefit of one or more groups of professional men ?

Prof. Collins recalled his experiences in 1939, when he assisted in forming Construction and Artisan Works Companies of the Corps of Royal Engineers from 600–800 building craftsmen who had answered the urgent call for volunteers in the Christmas broadcast of that year. He had served with those men in three theatres of war and lived with them for five years. By their training as apprentices, they had been made amenable to suggestion ; because of the pride each felt in his craft they required little supervision ; because they were used to working under the supervision of foremen they accepted discipline automatically. If the spirit of these volunteer craftsmen were present in the building industry to-day, then delays in production must come from other causes than their lack of willingness to deliver the goods.

In the course of general post-war increases in wages in the building industry, perhaps semi-skilled workmen and labourers had been unduly favoured at the expense of the more highly skilled workmen.

Were the post-war differences between the wages of craftsmen and of unskilled labourers sufficient to offset the drawbacks and hardship involved in the long apprenticeship required of the skilled trades ?

In conclusion, Prof. Collins referred briefly to the present position of research in relation to modern building, and mentioned several promising lines of possible development : the use of photogrammetry in town and country planning, the application to structural engineering of electrical methods of measuring strains which have proved successful in the aircraft industry, and the application of supersonic frequencies to the measurement and consolidation of materials.

The outstanding work which has been done and is still being done by the Government research departments, and by the institutions which they sponsor, should be supplemented by a pool of apparatus for research purposes, and by grants of fellowships to men who, by combining with research a limited amount of teaching, would hand on knowledge both of facts and methods to a wide circle. These considerations led to his last question.

In post-war reconstruction and planning, are the universities and technical colleges playing their full part in the advancement of building science and of research in structural engineering ?

Some of Prof. Collins' questions were purely rhetorical, and indicated no doubt as to the answer he might have given: others would be difficult indeed to answer at the present time; but all referred to problems which demand solution, and were aimed at stimulating thought and decision in those who must either take a lead in directing the future or perforce follow the direction of others less reticent.

Reading between the lines of Prof. Collins' questions, it is not difficult to trace the hope he had expressed with less reserve in the conclusion to his presidential address to the Institution of Structural Engineers a few weeks previously, that the "young members will in the future live to see the sun rise over the unshackled initiative of structural engineers; engineers who carry no fetters of Government regulation, no manacles of Local Authority restriction; but who have the free and unchecked initiative to plan and design that belongs by right to members of a profession that bears such heavy responsibility to society and to mankind".

STANLEY B. HAMILTON

ANTIBIOTICS

THE number of publications which record work on antibiotics has become so large that frequent evaluations of the progress of our knowledge of these substances have become essential. A conference devoted to these substances was held by the New York Academy of Sciences in January 1946, and the papers have now been published (*Ann. N.Y. Acad. Sci.*, **48**, Art. 2, 31; 1946). It is impossible to summarize these papers here, but a note on them will indicate their scope. They are arranged in two sections, one microbiological, the other pharmacological.

Dr. S. A. Waksman introduces the former with a paper on the contributions made by the microbiologist. M. J. Johnson describes the metabolism of penicillin-producing moulds, and K. B. Raper discusses the development of improved forms of them. W. J. Robbins, F. Kavanagh and Annette Hervey discuss the production of antibiotic substances by Basidiomycetes, S. A. Waksman, A. Schutz and D. M. Reynolds write on the production of antibiotic substances by Actinomycetes, and J. W. Foster and H. B. Woodruff deal with antibiotic substances produced by bacteria.

The pharmacological section is, with the exception of an article on the pharmacology of penicillin by G. Rake and A. P. Richardson and one on its use in the United States Navy by W. W. Duemling, devoted to the pharmacology of streptomycin and streptothricin. The first article on this subject is by H. Molitor. In another article H. J. Robinson discusses the absorption, excretion and chemotherapy of these two substances. The action of streptomycin on various micro-organisms and its use for the treatment of some non-tuberculous infections are discussed by E. Pulaski, A. Kleinman and G. G. Duncan. Its action on the bacillus of tuberculosis has given rise to the hope that it will be useful for the treatment of this disease; but the article here printed by H. C. Hinshaw and W. H. Feldman on the use of streptomycin for the treatment of clinical and experimental tuberculosis emphasizes the opinion expressed in an "Annotation" in the *British Medical Journal* (906, Dec. 14, 1946), that "it is at present quite uncertain whether streptomycin will prove, in the long run, to have great therapeutic value in tuberculosis". The same "Annotation" announces that committees appointed by the Medical Research Council will, when enough streptomycin becomes available, conduct trials of streptomycin for the treatment of types of tuberculosis likely to give clear evidence of its uses and limitations, and also trials of its action on certain non-tuberculous infections. The same cautious opinion of its possible efficacy for the treatment of tuberculosis is expressed by Dr. P. D'Arcy Hart in his Mitchell Lecture delivered to the Royal College of Physicians (*Brit. Med. J.*, 805, Nov. 30, and 849, Dec. 7, 1946) on the "Chemotherapy of Tuberculosis", a remarkable lecture with a full bibliography, which is discussed in an editorial article in the *British Medical Journal* (862, Dec. 7), together with the Harben Lectures on the same subject delivered by Dr. W. H. Feldman, of the Mayo Clinic. An interesting recent paper by D. G. Madigan, P. N. Swift and G. Brownlee (*Lancet*, 9, Jan. 4, 1947) indicates that what these authors call "the potential and actual toxicity of streptomycin" needs to be watched and investigated further.

Brief reference may also be made to the address given to the American Chemical Society in October of last year by Dr. L. C. Craig, of the Rockefeller Institute for Medical Research. Dr. Craig described a new method of isolating various forms of penicillin which frees the chemist from dependence upon boiling and melting points. This method, which is called 'counter-current distribution', uses the partition coefficient, which is a ratio indicating the diffusibility of a substance into cell protoplasm. The method employs a system of multiple transfers of the substance being studied through a series of separating funnels, so that the mathematics of the binomial theorem may be applied to interpret the results. Dr. Craig claimed that the method has disclosed at least seven types of penicillin and has indicated that there are many more. The method has also been applied to synthetic antimalarial substances.

CANADIAN RESEARCH IN GEODESY AND GEOPHYSICS

THE National Research Council of Canada has re-organised its Associate Committee on Geodesy and Geophysics (formed in 1945) and has given it authority to gather information on, and to direct and co-ordinate research in the field of, "geodesy and geophysics, including meteorology, hydrology, oceanography, seismology, vulcanology, magnetism, terrestrial electricity, tectonophysics, gravity, and any other subjects necessary to an integrated study of earth physics and geophysical prospecting". The chairman of the Committee is Prof. J. T. Wilson, professor of geophysics, University of Toronto.

The Committee is being provided with funds for the award of grants in aid of specific research projects to persons competent to direct work in this field and who have the required laboratory facilities at their disposal. Much of the work that interests the Committee is carried out as part of their normal duties by several Government departments and is paid for by those departments.

The integration and stimulation of geophysical work in Canada are desirable for several reasons: (i) geophysical methods of mineral and oil prospecting have assumed great importance, and this will continue; (ii) the Pre-Cambrian shield is the biggest and richest area of basement rocks in the world, and its study will throw light on earth structure as well as provide minerals; (iii) there are large areas of potentially useful oil-bearing rocks in western Canada; (iv) no other country is in so interesting a position geophysically, since Canada includes the north magnetic pole, and extends to the north geographic pole, and nearly to the magnetic axis; a larger part of the maximum auroral belt crosses Canada than any other country; (v) ionospheric studies for radio prediction have increased greatly during the War, and there are seven Canadian stations; the auroral belt will always produce peculiar effects; (vi) magnetic observations are lacking in northern Canada, where they are of value for navigation and of great interest near the magnetic pole.

More than a score of projects have already been initiated and further investigations are planned. One of the most fruitful subjects aided by the Committee has been the development of an airborne magnetometer. Fluxgate magnetometers were built by the National Research Council during the War; but these, it was known, would require extensive modifications before they could be adapted to airborne use. An early type was fitted to aeroplanes flying on Exercise Musk-Ox, in order to gain experience. In the United States, the Geological Survey had succeeded in adapting to geological use the magnetic airborne detector used in anti-submarine work, and it was thought this instrument would be suitable for use in Canada. The National Research Council obtained three sets from the United States Navy and modified them so that they will be available to the Department of Mines and Resources for use in Canada during the summer of 1947. Arrangements were made for a United States Geological Survey crew to bring a magnetometer to Canada and to make trial magnetic surveys of part of the Sudbury basin and of Louvicourt township. These surveys have been calculated, and the results will be published by the Geological Survey of Canada in co-operation with the United States Geological Survey.

In another project, mining and prospecting companies in Canada have co-operated with the Committee by supplying plans of magnetic readings for some of their properties. The Bourlamagne region in Quebec was chosen as a suitable area on which a regional map might be prepared from the magnetic survey data supplied by mining companies. Magnetic data for five townships have now been compiled and contoured. Comparison with the geology of the area will be made in a report now being prepared for publication.

A seismic study of the crust of the earth using rock-bursts as a source is projected for this season.

Geophysical work will continue to be done and paid for by existing departments, companies, and universities; but all this work will now be co-ordinated by the Associate Committee on Geodesy and Geophysics of the National Research Council. The Committee's work will not overlap that of the Geophysical Committee of the Geology Division of the Canadian Institute of Mining and Metallurgy, which deals with matters such as assessment laws, customs and tax rates, methods of procedure and professional ethics.

Steps have been taken to hold open meetings of the Associate Committee on Geodesy and Geophysics, the first of which was in connexion with the annual meeting of the Canadian Institute of Mining and Metallurgy at the National Research Building in Ottawa on January 23, 1947. The Committee proposes also to start publishing a bibliography on Canadian geophysics which will include reports on its activities.

RELAXATION METHODS APPLIED TO ENGINEERING PROBLEMS

IN this latest instalment* of Dr. R. V. Southwell's application of his relaxation method for the solution of the differential equations of physics, the problems treated are of a kind which are particularly intractable by classical methods—problems relating to the flow of a fluid having one or more free surfaces in a gravitational field. In addition to their practical interest, the results obtained present in an acute form the fundamental question of the extent to which the numerical approach can disprove the possibility of a particular type of solution.

When the relaxation method reveals the existence of a hitherto mathematically unknown flow pattern (as it does in this paper in connexion with the wakes formed by entrained air behind a cylinder or sphere travelling through a fluid), it can be shown that this solution satisfies all the required conditions, and is therefore authentic. But when the computation fails to reveal the existence of a solution which on general grounds might be expected to exist, to what extent is it proved that no such solution does in fact exist? Such a case arises in this paper in the treatment of the stream-line distribution caused by the passage of an inclined plane of infinite width over the surface of a fluid of finite depth. Apparently, in this two-dimensional problem it is impossible for the depth of the fluid to be the same before and after the passage of the plane—a result which may appear to be contrary to expectation. Perhaps the best approach to this question is to regard the relaxation method as an experimental rather than as a mathematical technique. The authors repeatedly stress the tentative nature of the relaxation process, and perhaps their results can be seen in the proper perspective if they are regarded as experiments carried out, as real experiments so seldom are, under ideal mathematical conditions. The failure of such an experiment to reveal a certain phenomenon does not disprove its existence; but a sufficient number of such experiments, carried out under various conditions, and all giving a negative result, may be taken as demonstrating that the phenomenon does not occur in practice—which for the engineer is equivalent to a disproof of its possibility.

The paper also contains numerical solutions to a number of other problems, including the well-known case of the circular weir-Borda flow in three dimensions. From the point of view of computational technique, these problems are among the most difficult that have been attempted by relaxation, and the authors are to be congratulated on the successful conclusion of what must have been a formidable volume of arithmetic.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, March 18

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. S. Herbert Frankel: "Whither South Africa?"

Society of Chemical Industry, Agriculture Group (in the Physical Chemistry Lecture Theatre, Royal College of Science, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. L. Leyton and Mr. G. W. Dumbleby: "Soil Conditions and Tree Growth".*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. E. B. Ford: "Recent Advances in Genetics".

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Prof. John Read, F.R.S.: "Historic St. Andrews and its University".

Royal Anthropological Institute (joint meeting with the International African Institute, at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Mr. G. I. Jones: "The Aba Market and Ibo Distributive Trade".

Institute of Petroleum, Northern Branch (at the Engineers' Club, Albert Square, Manchester), at 6 p.m.—Dr. Whalley: "Progress on the Synthesis of Fuels and Lubricants".

Chemical Society, Nottingham Section (in the Large Chemistry Theatre, University College, Nottingham). at 7 p.m.—Dr. A. E. Alexander: "The Application of Surface Chemistry to Colloidal Problems" (Tilden Lecture).

Royal Institute of Chemistry, Manchester Section (at the Grand Hotel, Manchester), at 7 p.m.—Sir Henry Dale, O.M., F.R.S.: "Chemistry and Medicinal Treatment" (Dalton Lecture).

Society of Dyers and Colourists, Huddersfield Section (at Field's Café, Huddersfield), at 7.30 p.m.—Dr. F. Townend: "The Use of Acids in Wool Dyeing".

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the Welwyn Garden City Scientists' Club, at The Cherry Tree, Welwyn Garden City), at 8 p.m.—Dr. A. M. Ward: "The Training and Qualification of Chemists".

Wednesday, March 19

Physical Society (in the New Physics Lecture Theatre, The University, Manchester), at 10 a.m.—Conference on "Meteors, Comets and the Radio Detection of Meteors" (Fellows of the Royal Astronomical Society are invited).

Physical Society, Low-Temperature Group (at the Clarendon Laboratory, Parks Road, Oxford), at 12 noon–1 p.m.—Survey of the Work of the Low-Temperature Department of the Clarendon Laboratory; at 2 p.m.–3.45 p.m.—Short Talks on Selected Topics and Tour of the Laboratory.

British Society for International Bibliography (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Beginners' Questions on the Use of the Universal Decimal Classification Answered.

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the London Branch of the Institute of Physics, at the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m.—Prof. E. K. Rideal, F.R.S.: "Monomolecular Layers".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Annual General Meeting. Dr. A. E. Trueman, F.R.S.: "Stratigraphical Problems in the Coalfields of Great Britain" (Presidential Address).

Institution of Post Office Electrical Engineers (at Faraday Building, 9th Floor, South Block, Knightrider Street, London, E.C.4), at 5 p.m.—Mr. W. J. Ford: "A Review of Compressed Air Technique and its Practical Application".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Prof. Douglas Hay: "British Coal Mining and the Industrial Revolution, with special reference to the Life and Work of the late Lord Cadman" (Cadman Memorial Lecture).

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. L. F. Broadway, Dr. C. J. Milner, Mr. D. R. Petrie, Mr. W. J. Scott and Mr. G. P. Wright: "Velocity Modulation Valves".

Sir John Cass Technical Institute (at Jewry Street, Aldgate, London, E.C.3), at 6.15 p.m.—Dr. G. M. Dyson: "The Dyson System of Indexing Organic Compounds".

Society of Chemical Industry, Food Group (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Dr. W. G. Ogg: "A Survey of the Work of the Rothamsted Experimental Station" (members of the Agriculture Group are invited).

Society of Dyers and Colourists, Midlands Section (at the King's Head Hotel, Loughborough), at 7 p.m.—Dr. John H. Hill: "The Chemistry and Application of Detergents".

Thursday, March 20

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 12 noon.—Annual General Meeting; at 3 p.m.—Prof. C. N. Hinshelwood, F.R.S.: Presidential Address.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. H. D. Megaw: "Temperature Changes in the Crystal Structure of Barium Titanium Oxide"; Mr. C. W. Bunn and Mr. E. V. Garner: "The Crystal Structure of Two Polyamides ('Nylons')".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. A. Ostrowski: "The Different Types of Convergence in Formal and Numerical Analysis".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. A. W. Groves: "Results of Magnetometric Survey at Benallt Manganese Mine, Rhiw, Caernarvonshire"; Messrs. A. King, A. Clemes and H. E. Cross: "The Treatment of Gold Ore containing Pyrrhotite at the Sub Nigel, Ltd.".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. E. P. G. Wright: "The Modernization of the International Telephone Service and its Reaction on National Telephone Systems".

Institute of Fuel, North-Western Section (at Radiant House, Bold Street, Liverpool), at 6.30 p.m.—Mr. F. Aldred: "Water Treatment".

Chemical Society, Aberdeen Section (joint meeting with the Local Section of the Royal Institute of Chemistry, in the Chemistry Department, Marischal College, Aberdeen), at 7.30 p.m.—Prof. E. L. Hirst, F.R.S.: "Recent Developments in the Chemistry of Starch and Glycogen".

Royal Microscopical Society (joint meeting with the Electron Microscope Group of the Institute of Physics, in the Great Hall of B.M.A. House, Tavistock Square, London, W.C.1), at 7.30 p.m.—Mr. J. Smiles: "Survey of the Inter-relationship of Microscopical Techniques".*

Royal Society of Tropical Medicine and Hygiene (at the Royal Army Medical College, Millbank, London, S.W.1), at 8 p.m.—Laboratory Meeting, and Demonstrations.

Friday, March 21

Physical Society, Optical Group (in the Physics Department of the Imperial College, Imperial Institute Road, London, S.W.7), at 3 p.m.—Mr. W. C. Hynd: "The Physical Properties of Glass"; Mr. T. H. Wang: "The Degree of Inhomogeneity of Optical Glass and some Aspects of its Bearing on Optical Performance".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion on "Modern Methods of Time-Keeping" (to be opened by Sir Harold Spencer Jones, F.R.S.).*

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. M. E. Haine: "The Design and Construction of a New Electron Microscope".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Discussion on "The Combination Torque-Converter and Fluid-Coupling Drive" (to be opened by Mr. B. J. Tams and Mr. A. L. Gatiss).

Society of Dyers and Colourists, Manchester Section (at the Gas Department Show-rooms, Manchester), at 6.30 p.m.—Mr. J. Henderson: "Temperature Range Properties of Vat Dyes on Rayon".

Society of Dyers and Colourists, Scottish Section (at St. Enoch Hotel, Glasgow), at 7 p.m.—Mr. J. R. F. Jackson: "Emulsions for Textiles".

Royal Microscopical Society (joint meeting with the Electron Microscope Group of the Institute of Physics, in the Great Hall of B.M.A. House, Tavistock Square, London, W.C.1), at 7.30 p.m.—Prof. W. T. Astbury, F.R.S.: "The Electron Microscope".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. D. Brunt, F.R.S.: "Where to Live—a Meteorological Problem".

Saturday, March 22

Institution of Chemical Engineers, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 3 p.m.—Mr. H. R. C. Pratt: "Purification and Azeotropic Dehydration of Acetonitrile".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Assistants (3) in Economics—The Registrar, The University, Manchester 13 (March 31).

Lecturer in Ancient Philosophy—The Secretary, The University, Edinburgh (March 31).

Head of the Department of Horticulture, and a Lecturer in the Biology Department, at the Essex Institute of Agriculture, Writtle—The Chief Education Officer, County Offices, Chelmsford (March 31).

Lecturer-in-Charge of the Chemistry Department, and a Lecturer-in-Charge of the Mechanical Engineering Department, in the Technical Education Branch of the Department of Public Instruction, Sydney—The Official Secretary, New South Wales Government Offices, 125 Strand, London, W.C.2 (March 31).

Robert Blair Fellowships (2) in Applied Science and Technology—The Education Officer (H.1/2), London County Council, County Hall, London, S.E.1 (April 1).

Lecturer in Physiology, and a Laboratory Superintendent, at Makerere College, Kampala, East Africa—The Secretary, Inter-University Council, 8 Park Street, London, W.1 (April 1).

Lecturer in Chemistry and Soil Science at the College in Trinidad—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2 (April 7).

Readership in Psychology tenable at the Institute of Education—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 24).

Entomologist with special interest in and knowledge of the Coleoptera, and an Entomologist with special interest in and knowledge of the Hymenoptera—The Director, Imperial Institute of Entomology, 41 Queen's Gate, London, S.W.7 (June 1).

MINING POLICY IN BRITISH COLONIAL TERRITORIES

THE Secretary of State has issued a general directive to Colonial Governments, dealing with policy in mining and mineral exploitation*. The subject is clearly of much importance, and it cannot be too concisely or clearly set forth; discursive statements are not appropriate in a document of this character. The present memorandum contains matter that is trite and redundant, and it might have been better arranged.

The memorandum properly stresses that minerals are a wasting capital asset, and that the first step in mining policy must be the determination of the extent of such resources; for example, by geological surveys. This, of course, is a fundamental need; and the interest now being shown by the Colonial Office in the mineral field, and its recognition, as shown by the appointment of Dr. F. Dixey, formerly director of the Geological Survey of Nyasaland, as adviser to the Secretary of State in all geological matters, of the need for expert services, are encouraging. A reason why systematic survey has come rather late in the history of most territories is that individual mining enterprise has often been the first means of developing and settling regions which would otherwise have remained unattractive; the risks undertaken by private enterprise are rarely contemplated by a State Department.

Two paragraphs (5 and 6) contain strong pleas for the vesting of all mineral rights in the Crown. There are many good arguments in favour of this principle, which has, in fact, received general recognition for many years past, outside the British Isles; its main object being to provide some measure of control over the exploitation of natural resources for the general benefit of the community. This indeed is stated in the preface to the memorandum. One may cite as an example the acquisition of the mineral rights in Southern Rhodesia for the Dominion from the B.S.A. Company. (In parenthesis, it may be observed that bad early legislation gave rise to one of the worst mining law-suits in history within this territory.)

A good measure of indirect control can also be obtained by wise taxation; for example, on the Witwatersrand a sliding scale has been applied, by which the mining of low grade ores is encouraged, and the life of the field prolonged accordingly. In the paragraphs dealing with royalties and taxation (p. 8) it is observed that some such system is being considered for gold mining in Tanganyika and Fiji, in lieu of the standard rate of royalty usual in most Colonies, and may be extended to other forms of mining if practicable.

Since the whole problem of the relation of mining to the community has been the subject of intensive study in the Union of South Africa for many years, it is surprising that the question is only now under consideration for the Colonies. Conditions there do not much resemble those in Great Britain, and have no parallel in the British coalfields; but are more nearly aligned with those in the great mining Dominions. Is it too much to hope that the Colonial Office may look to their example and practice for guidance? In many of these, private enterprise has been the foundation of lasting prosperity and has much to be proud of. It should not lightly be subordinated to current political theory. One suspects, however, that the arguments favouring State control bear some direct relationship to the density of population. Sparsely populated and undeveloped territories are still very dependent upon the efforts of individuals toward their progress.

---

* Memorandum on Colonial Mining Policy. (Colonial N.206.) Pp. 10. (London: H.M. Stationery Office, 1946.) 2*d*. net.

In advocating the ownership and operation of active mines by the State, the memorandum is on far less secure ground. Once a series of highly technical operations is subject to modification by political desiderata, its efficiency must fall. There is an ever-present risk of jobbery; the danger that a Government may only acquire well-developed or profitable properties; suppress legitimate ventures; or squander public funds unjustifiably. In the case of bodies set up by the State, there may be no general meetings at which shareholders and the Press are represented; and the staffs are not subject to the strict rules and discipline of the Civil Service. It is stated that "mining should be carried on according to a deliberately planned programme and its social consequences carefully foreseen and directed . . ." (par. 7). The fact is that, except in certain large well-explored and well-developed fields, mining is too much of an adventure into the unknown to permit of long-range forecasting. That is why, presumably, a policy of short-term leases is advocated (p. 6).

It is twice indicated in the memorandum that Governments should control the rate of exploitation of minerals. This statement requires amplification. The ultimate goal must be to recover the maximum possible quantity of an irreplaceable commodity at a reasonable expense. Nevertheless, it is wise to maintain a strategic reserve within any territory; so that the rate of production must adjust itself to the ascertained reserves, to the demand within the Colony, and the permissible rate of export or other mode of dispersal of minerals. Some form of subsidy for minerals in short supply or of low concentration may well be justified. Once mining has become established, it is subject to regulation by many imponderable factors, and the expert in charge must have the last word, whether the mine is privately or publicly operated. An artificial fluctuation of output or a premature shut-down may cause infinitely more mischief than controlling the production of a factory. It cannot be emphasized too strongly that adequate ore reserves should be developed by exploration before there is major expense on ancillary operations such as provision of plant, power, transport and water supply. The failure to observe this principle has often been one of the weaknesses of private enterprise.

The statement appearing on page 9 of the memorandum that "Governments should seriously consider public exploitation wherever practicable", notwithstanding the diverse conditions in the Colonies, may suffice as a direction to officers of the Crown; many others, however, will not be prepared to accept unchallenged a general statement of this character. Too much depends on the interpretation of the qualifying phrase "where practicable".

The question of mineral resources is now one of world importance; if distress and strife are to be avoided, some world-wide pool for the conservation, distribution and recovery of mineral products may well have to be established. But if, as the present memorandum indicates, minerals are "a gift of Nature to be shared", they are not won without hard planning, work and risk. A distinction must be made between legitimate wants and an importunate clamour for the fruits of someone else's labour. The consequences of mineral policy during the last two decades in the two great mining countries, Mexico and Brazil, where the doctrine of national ownership has been promulgated, might well repay closer study.

Much of the memorandum, however, concerns itself with matters that are normally dealt with by mining engineers or mining economists within individual territories; for example, by the Government Mining Engineer in South Africa, or the Bureau of Mines in Canada; and Colonial Governments must necessarily attach considerable weight to the opinions of their local expert advisers. A close liaison between them and the home authority is eminently to be desired; but too narrow a direction may well be out of place. Some recommendations in the memorandum could only be decided by an expert on the spot.

In securing expert services there is the urgent problem of providing suitable training for geologists and kindred workers in the various Colonial territories. Not all the British universities can provide teachers with the requisite Colonial experience, nor can the British Isles afford a wholly appropriate training ground. In this respect, Canada, Australia and South Africa are more fortunate; and recruits to the Colonial Geological Survey Services ought to be given facilities for special training and experience in the Dominions as well as in Britain.

X-RAY CRYSTALLOGRAPHY IN INDUSTRY

Radiocristallographie

Par André Guinier. Pp. ix+294+16 plates. (Paris: Libr. Dunod, 1945.) 725 francs.

DURING the last twenty years X-ray crystallography has found many industrial applications in France as elsewhere. The present volume is written for the industrial man of science who requires a broad knowledge of the applications of the subject.

The first chapter gives a short account of the properties of X-rays, the second chapter describes very briefly the types of X-ray tubes and high-tension equipment at present in use. The third chapter gives a summary of the theory of crystallography in so far as it is necessary for the determination of cell dimensions; but it is the author's expressed intention not to include a discussion of space-groups or of the methods of finding actual atomic arrangements within the unit cell. Chapter 4 gives an account of the principles of X-ray powder photography, and Chapter 5 discusses the taking and interpretation of rotating-crystal and of Laue photographs. The concepts of the reciprocal lattice and of the reflecting sphere are used; but the discussion of them is rather too brief to enable a serious student to understand the problems fully. The omission of moving-film photographs is surprising seeing how many applications they now have. One of the author's main contributions to recent developments in X-ray crystallography, namely, the use of the focusing monochromator, is described in Chapter 6. Though introduced originally by Johannsen in Sweden, the focusing monochromator has in recent years been more developed and applied in France than elsewhere. This book contains a number of the author's beautiful photographs taken with this monochromator; and for many purposes where freedom from background fogging is necessary, it is particularly valuable. Chapter 7 deals with the study of crystal texture, and includes both the determination of the size of small crystals and the preferred orientation of crystals in polycrystalline aggregates. This discussion also is rather brief, and the omission of the use of charts of constant θ-, ρ- and ω-values is unfortunate. The absence of references to moving-film methods of studying preferred orientation also restricts the usefulness of this chapter. Chapter 8 deals with the connexion between cell dimensions and chemical composition, particularly in relation to solid solution in alloys. A short section is devoted to the measurement of internal stresses in metals by the changes in cell dimensions induced by those stresses. Chapter 9, on superlattices, leads on to a more general study of imperfections in crystals in Chapter 10. This chapter includes the study of the influence of the size of crystals, of thermal agitation and of the effects of cold-working on the breadths and intensities of powder lines. Chapter 11 deals with diffraction by liquids and amorphous bodies. The twelfth and last chapter describes another special contribution of the author to this subject, namely, the use of the scattering of X-rays at very small angles from the incident beam to determine the shape and size of the particles. This method, which is applicable to aggregates of particles ranging in size between 20 and 500 A., no matter whether they are crystalline or amorphous, is likely to yield valuable information on colloidal substances which is complementary to that which can be obtained by other X-ray methods.

The nine appendixes deal with various proofs of fundamental theoretical relations and with a short account of the use of the stereographic projection. Among the tables there is one very useful table of spacings in relation to Bragg angles for cobalt $K\alpha$ radiation, which is not given in the "International Tables for Crystal Structure Determination". The sixteen plates contain some beautiful X-ray photographs which reveal the great advances made in technique by the use of strictly monochromatic radiation.

In conclusion, the author is to be congratulated on producing, just at the end of the War, and under the difficult conditions which then prevailed in France, a work which will be much appreciated not only in his own country but also in every country where X-ray crystallography is studied.

W. A. WOOSTER

THE COAST OF ENGLAND AND WALES

The Coast-line of England and Wales

By J. A. Steers. Pp. xix + 644 + 117 plates. (Cambridge: At the University Press, 1946.) 42*s*. net.

THE appearance of a large and well-illustrated volume dealing with the shore-line of England and Wales is a notable event. Several books have been written about parts of our coasts, but there has hitherto been no full-length study of the coast as a whole, and Mr. Steers is warmly to be congratulated on the completion of so extensive a task and on the successful publication of his work at this time.

Essentially, Mr. Steers' approach is that of the physiographer concerned with the factors influencing coastal forms, and he has included a chapter dealing with such general physiographical considerations as wave action and the movement of shore material, the orientation of beaches and the forms of cliffs. In the eight chapters dealing with particular sections of the coast he has emphasized these aspects of shore-line evolution, at the same time directing attention to the geological conditions which have largely controlled the development of major features both of coastal and inland areas. The close relationship between the nature of the coast-line and the previous history of the area of which it forms the present boundary is a constant theme. Thus much attention is given to changes of relative level of the sea, which have influenced the erosion both of the coast and adjoining land areas. A special chapter towards the close of the volume deals with these recent vertical movements of the shore-line, and present knowledge of their chronology is summarized: but the author well realizes the wide divergencies of opinion regarding problems such as the correlation of raised beaches in distant areas, and the reader is warned that final conclusions are not yet in sight.

The difficulty of a simple classification of our coasts is fully recognized, since in many areas a succession of emergences has been followed by a comparatively recent submergence. As the author points out, "it is clearly difficult to regard much of the Welsh coast as merely either submerged or emerged", and a similar statement would be justified in most parts of Britain. In some areas the results of submergence, and in others the results of emergence, are outstanding, owing to the previous contour of the land or adjacent sea bed.

In his survey of the coasts, as he himself notes, the author has given rather more space to the flat coasts than to cliffed coasts. In the former he finds that there is often an interesting physiographical evolution to trace, while in the latter it is hard to provide much more than a dull statement of rather obvious facts. He notes, however, that there seems "to be scope for a good deal of very interesting work on the intricate details of many miles of rock-bound coast", and suggests that the stratigraphical geologist working on a coastal area could often aid greatly in an understanding of the development of cliff forms. It may be suggested that the preparation of diagrammatic interpretations of the geological structure of the cliff (as in Fig. 102 in this book, showing a part of the Yorkshire coast, and Fig. 51 of Dorset) would enable many physiographers to appreciate very rapidly the essential factors in the structure and to see their relationships to cliff form. Indeed, it would have been a great help to many non-geological readers if such geological diagrams of the cliff face of various areas had been more freely introduced by the author, and it may perhaps be hoped that he will consider this when a new edition is called for. Details of cliff form are so closely related to geological structure that large-scale diagrams may be very illuminating. We may feel some sympathy with Mr. Steers in this matter, however, for notwithstanding the great variety of cliff profiles, caves and headlands, the description of numerous examples of the relationship of rock structure to cliff pattern, so easy of interpretation in most cases, is not a task in which many will find inspiration.

While the author discusses much detail of coast patterns, he has not neglected some of the wider features. Particularly interesting is his treatment of the more notable inlets, such as the Wash, the Thames estuary and the Bristol Channel. The origins of the two latter are compared, and although the surface geology of the two areas is very different, attention is called to suggestions that both are due to Miocene movements, possibly influenced by structures of earlier date. It may be noted that the boundary between Palæo-Europe and Meso-Europe extends approximately parallel to these depressions, and the Bristol Channel at least follows a belt which separated regions of different character both in early and later Palæozoic times; it may correspond to a belt of great tectonic significance. Several lines of evidence point to the occurrence of post-Jurassic (presumably mid-Tertiary) movements in the Bristol Channel area; among these the occurrence of sharply folded and thrust Lower Lias on the Channel shore of North Somerset is important, though its significance in this connexion has not been stressed. Prof. O. T. Jones produced a contour map of the base of the Lias in part of the area, showing marked folding which he suggested had resulted from Miocene movement. Mr. Steers correctly notes, however, that intra-Liassic folding may account for some at least of this folding (p. 191); moreover, later Jurassic movements (especially pre-Vesulian movements) in the Mendip area were such that the amount of Tertiary folding is not readily determined from the form of the Lias base. Mr. Steers also directs attention to the fact that the Bristol Channel consists of two parts, an east-west section which may be regarded as extending eastwards into the flats south of the Mendips; and a north-easterly section, the Severn estuary, the origin of which has not been fully explained, though it is related to the structural features.

It will be seen that Mr. Steers has written a book which is likely to stimulate geologists, physiographers and others to a livelier interest in coast features. He has taken a wide view, and has written much also of interest to the ecologist. Here and there he has introduced notes on coast protection and its problems, while he comments on many matters relating to the use of the coast-line and to its preservation. In short, this book should be consulted by many readers besides students of those subjects for whom it is written. If, as we may hope, many parts of our coasts are preserved for the benefit of those who wish to enjoy their beauties or to investigate the scientific problems they present, this book will provide information for those who are responsible for selecting the stretches of coast-line or for their maintenance.

It remains to add that there are two introductory notes, by Prof. L. Dudley Stamp and Sir Patrick Abercrombie; that there are numerous diagrams and maps (a few unfortunately without a scale—a real disadvantage for the reader); and that there are 115 photographs showing features from all parts of the coast, besides two very beautiful colour photographs.

A. E. TRUEMAN

NATIVE FARMERS AND BRITISH INDUSTRY

Colonial Agricultural Production

The Contribution made by Native Peasants and by Foreign Enterprise. By Sir Alan Pim. (Issued under the auspices of the Royal Institute of International Affairs.) Pp. ix + 190. (London, New York and Toronto: Oxford University Press, 1946.) 10*s*. 6*d*. net.

THE history of emigration and settlement contains little which our own or any other colonizing State can contemplate with much satisfaction, when considered in relation to the native populations of the countries colonized. For long years the natives were at best sources of cheap labour for the enterprises initiated by the colonists, and it would be no exaggeration to say that any consideration for them, any recognition of their organisations and social institutions, or any feeling of responsibility for the improvement of their economic condition, are things of very recent growth. The idea of trusteeship for backward peoples, always present in our best administrators, was not generally recognized by British public opinion until well into the present century. Even to-day, it could not be said that the interests of those controlling the capital invested in plantation agriculture are always pursued with due regard for the native communities upon whom they depend, almost exclusively, for manual labour. The importance of the Colonies, however, in our national economy is even greater to-day than it was before the great changes in the commercial structure of the British Empire and its relations with other countries brought about by the War. The problem is how to develop their great latent resources in the interests alike of the Empire and of the native populations, and this, in the main, is the problem with which Sir Alan Pim deals in his new book, which is published under the auspices of the Royal Institute of International Affairs.

No one is better qualified than he either to describe the conflict of interests, where such exists, and to pronounce judgment upon it, or to direct our attention to the great field of work still awaiting our administrators in the Crown Colonies, in raising both the social and the economic standards of life among the native races. Following a distinguished career in India, Sir Alan has been employed by the Government on special missions to Swaziland and Zanzibar, Bechuanaland, Basutoland, Kenya, Northern Rhodesia, among British African dependencies, and to British Honduras. Thus he had been able to study the problem over a wide range of territories and races, exhibiting every stage of development in agriculture, from the entirely primitive native production to the highly developed plantation industry, and every stage of culture from the untutored savage to the native graduate at a British university.

The results of his study are presented geographically in his recent book: the Netherlands Indies, Malaya, Ceylon and Mauritius; Fiji and the West Indies; the tropical African dependencies; and British Central and East African dependencies. Sir Alan quotes Lord Hailey for the statement that "it has been an outstanding tenet of British Colonial policy that peasant production is to be preferred to any of those forms of development involving the use of imported capital and management, which are generally known as the 'plantation system'". It would be interesting to know when this became the official policy, for there is little in the organisation, for example, of so young a colony as Kenya, to suggest that the Home Government had been seriously concerned, from the first, to promote the agricultural development of the natives. However, this is only one issue; and not the least interesting feature of Sir Alan's book is his description of the great variety of social and economic conditions with which the administrations have to contend. Not only is there the question of getting a 'square deal' for the natives under the plantation system, there is also the difficult problem of improving the technique of great numbers of native producers who are misusing the land or failing to use it fully, to the detriment in either case of their standards of life; and lastly there is perhaps the most important consideration of all, how can the native standard of farming be raised in association with the production of a market crop?

Native producers the world over are mainly subsistence farmers, and only by the evolution of a land utilization system which can combine self-supply with steady production for the market will it be possible to introduce or to extend a cash economy, in the interests alike of the native countries and of the highly organised States such as Britain, who have assumed responsibility for their administration. The self-sufficient peasant or native farmer has a strength that no other class of any community can show, for he need never starve. At the same time, his standard of life is generally a low one, often falling below an adequate nutritional level, and the only escape is by the practice of some form of husbandry which will enable him to enter the market with something to sell. Immediately, he becomes a purchaser of other requisites than food, or of foods with which to supplement the deficiencies of his own culture, and there is a general rise in the economic level of the community.

How to bring about these conditions would seem to be the principal aim of British Colonial administration. It involves education, finance, health services, and public works of all kinds for opening up the territories. Sir Alan writes with authority on all these subjects, and on the special difficulties which have to be faced in each of the countries reviewed—problems of land tenure, for example, or of credit, or of training for the labourer, particularly in the use of labour-saving appliances and machinery. In some countries, physical and climatic conditions call for heavy expenditure on capital works such as irrigation, if agricultural production is to be possible. In other countries, the populations are so sparse that labour may have to be imported; in others again, too densely populated, the subdivision of land has gone too far for good living, and the organisation of other industries for alternative employment is pressing. At the present time, much is to be hoped, and may even be expected, from the development of native agriculture, alike in the interests of the agriculturists and of British trade and industry.

C. S. Orwin

SCIENCE AND THE HISTORY OF SOCIETY

The Path of Science

By Dr. C. E. Kenneth Mees, with the co-operation of Dr. John R. Baker. Pp. xii+250. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1946.) 3 dollars.

In this book the author has expanded a course of lectures on the development of science and its relation to the history of society, recently given by him as Hitchcock professor at the University of California. The first of its ten chapters deals with the interpretation of history, and the different conceptions that have been put forward, namely, unique events, cycles of civilization, and the idea of progress. Dr. Kenneth Mees rightly directs attention to the separation of humanistic learning from scientific knowledge, and adds: "The humanists must understand what the scientists have done in the past, are doing now, and may do in the future; while the scientists must see their work in the light of history and in relation to the effects that its application to social conditions will produce".

The second chapter is an attempt to reconcile the various conceptions of history. The theme is the 'Helix of History', which admits of a vertical component as well as indicating the idea of revolutions of civilization. The frontispiece shows how the helix may steadily increase the separation of its coils, and then, suddenly, after the discovery of the methods of experimental science, spring upward in an almost vertical direction.

Chapters 3 and 4 deal with the method of science and its development. Reference is also made to the sense of 'frustration' felt by such writers as Prof. J. D. Bernal, and it is pointed out that it is not organisation that will solve the difficulty, but more knowledge. With regard to the latter, it is "quite impossible to predict in advance whether any particular scheme of scientific work will produce results which can be 'applied'". Explanations are reviewed of the unique phenomena of the seventeenth century, and reference made to the comparatively small number of those responsible for scientific development since that period.

About one third of the book is devoted to a comprehensive survey of the growth of the major sciences—physics, chemistry and biology. In the words of the author, this forms a "résumé of the ideas of science and the methods by which these ideas have been evolved. A brief account of science intended to give a picture of the whole to an educated man." The growth of physical and chemical ideas is traced by Dr. Kenneth Mees, and indicates a wide interest of subject, culminating in atomic fission and the cyclotron. Chapter 7, "The Growth of Biological Ideas", is written by Dr. John R. Baker, lecturer in zoology in the University of Oxford, who with a wealth of knowledge and experience traces the development of modern biology from 1537, the year in which Vesalius settled in the University of Padua. Reference is made to individual work, as well as to broad lines of development. The chapter concludes with a plea that physiology should break loose from subservience to medicine; then "we may look for rapid progress in our understanding of the processes of growth and differentiation".

The remainder of the book deals chiefly with the organisation of research—whether for basic scientific knowledge, or in the more applied form of industrial research; and Dr. Kenneth Mees' experience—he is vice-president in charge of research, Eastman Kodak Company, Rochester, New York—gives weight to his analysis of the problem. The book concludes with a short chapter in which the "Path of Science" is reviewed, particularly with reference to methods of government and political leadership.

H. D. Anthony

TEACHING OF INORGANIC CHEMISTRY

General and Inorganic Chemistry

For University Students. By Prof. J. R. Partington. Pp. xxiii + 916. (London: Macmillan and Co., Ltd., 1946.) 36*s*.

HOWEVER much a new text-book from an authoritative writer may be welcomed, an even warmer reception usually awaits a well-established text after searching revision. Prof. Partington's "Text-Book of Inorganic Chemistry for University Students" is familiar to every student of chemistry, and an up-to-date text-book, planned in a generally similar way and from the same pen, is a valuable addition to our teaching resources. The new "Partington" is a distinct advance on its predecessor, particularly in the provision of much-expanded sections on the chemistry of the less common elements.

The book is divided into two distinct sections. The first, comprising rather less than one third of the text, is an outline of classical physical chemistry, at a standard adequate to provide for intermediate and university scholarship candidates. The second section treats the chemical elements in the order of groups in the 'short' Periodic Table; this section is of substantially higher standard than the first, and it is designed as a basis for work up to general degree level in inorganic chemistry, the intention being that honours students should read the more advanced aspects of the subject in original papers and specialized texts. The book thus provides all the physical and inorganic chemistry needed by a university scholarship candidate, with sufficient additional material in inorganic chemistry to make it useful right up to the honours degree examination. The policy of covering so much ground in a single volume is perhaps open to question, but Prof. Partington's succinct style of writing and careful selection of material have ensured thorough treatment of the whole field, and consequently a wide appeal for his book.

The general and physical chemistry section of the book is well planned on conventional lines, and proper attention is given to atomic and molecular weights, the kinetic theory, the phase rule, solutions, thermochemistry, electrochemistry, and chemical and electrochemical equilibria. Four chapters at the end cover the Periodic Law, modern atomic theory, the solid state, and the quantum theory of the atom and of valency; these chapters provide a basis of general principles for the inorganic section of the book. Unfortunately the pace of recent developments and war-time restrictions have been such that the treatment of radioactivity will need considerable expansion at an early date. The discussion of valency affords a useful picture of modern views without being too highly theoretical, and is well adapted to students' needs. The sections on the structure of solids, however, are disappointing, and do not sufficiently reflect the basic importance of structural concepts in the inorganic chemistry of solids. Non-stoichiometric relationships in solids, particularly, merit more consideration in view of the rapidly growing appreciation of their fundamental significance.

The inorganic section of the book, considered as a concise and accurate presentation of chemical facts, is uniformly excellent, and the author is to be congratulated on covering a large and diverse field of knowledge in a way that is open to little detailed criticism. However that may be, the general approach to the subject as a whole is unattractive; in its condensed and rather uninspiring presentation of factual chemistry, the book may tend rather to weaken than to arouse interest in the inorganic field. Admittedly there is no short cut to a knowledge of the descriptive chemistry of the elements, and for this reason the adoption of a simple system of treatment based on the Periodic Table merits hearty commendation; too early an attempt to systematize the facts of inorganic chemistry leads to disillusionment when the exceptions are discovered to be far too numerous to prove the rules. Nevertheless, many branches of modern inorganic chemistry lend themselves to discussion in such a way that broad lines of progress are emphasized, and genuine interest promoted in the reader. The present work retains the classical style of inorganic text-books rather too tenaciously.

Prof. Partington maintains in his preface that students should consult original papers in the course of their studies, and he gives a century-old quotation by George Fownes in support of his view. During the past century, however, inorganic chemistry has developed rapidly, particularly in the application of new experimental techniques, and university courses have also changed a good deal. Modern students complain, not without good reason, that they are expected to read far too much; they will scarcely welcome the author's suggestion that his admittedly concentrated survey is intended as a companion to more or less extensive reading elsewhere. They will find it a hard task, in fact, to use the book in this way. The references are too numerous and insufficiently discriminating, and unless they are followed up with a measure of wisdom uncommon in students they will lead to a detailed knowledge of a few selected topics, at the expense of a broad general acquaintance with inorganic chemistry. Certainly a graduate in chemistry should have studied original memoirs of recognized merit; but their selection requires much more definite guidance than this book affords. In inorganic chemistry, original papers are best used in the study of special experimental methods and their application, which usually possess sufficient inherent interest to hold the reader's attention and infuse in him something of the spirit in which the science has developed.

Prof. Partington's book deserves popularity, but its limitations should be realized and counteracted by wise counsel from the teacher—an indispensable adjunct, after all, to any university course. If the book arouses interest in the whole subject of teaching methods in inorganic chemistry, Prof. Partington's service to chemists, already great, will be yet greater.

Adequate descriptions of lecture experiments are given throughout the book. The diagrams are clear and well chosen, and the standard of printing and production is high.

A. J. E. Welch

THE INDIAN SCIENCE CONGRESS

DELHI MEETING

By SIR CHARLES DARWIN, K.B.E., F.R.S.

THE thirty-fourth Indian Science Congress was held at Delhi between January 1 and January 8, and was attended by delegations from various countries. From Great Britain delegations were appointed by both the Royal Society and the British Association, and it is appropriate to recall that nine years ago the British Association had sent a large party to the twenty-fifth Congress, when it met in Calcutta. I had the privilege to be a member of that earlier party, and it was pleasant to renew acquaintance with Indian friends, and interesting to witness the progress in science made in the interval. The other delegations were from Canada, the United States, France, the U.S.S.R. and China, and we were all treated in a most generous manner by our hosts, who bore all the expenses of our stay in India, arranged for our tours to all parts, and looked after us most considerately the whole time.

As to the personalities of the Congress, the president was Pandit Nehru, who managed to spare a very considerable amount of time from his other activities, both in attending the meetings and in entertaining the visitors; it is encouraging to see what a large place the furtherance of scientific development plays in the plans of the political leaders. The chief part in organisation was played by Sir Shanti Bhatnagar, who occupies in the Government of India a position akin to that of the secretary of the Department of Scientific and Industrial Research in Great Britain. It is largely due to him that India is establishing no less than five new government-controlled research institutions, one of them in physics, but of this more below [see *Nature*, February 8, 15 and March 1]. The secretaries were Prof. P. C. Mahalanobis, the statistician, and Prof. D. S. Kothari, the physicist. In addition to the others who assisted in the organisation, special mention should be made of a large body of 'volunteers', students of the University of Delhi, who seemed to be able always to give the right kind of help, whether in setting up a lantern, re-arranging chairs, taking messages, or clearing gangways, without, so far as one could see, any instructions at all.

Apart from the Russians, who of course came by a different route, most of the delegates flew together from London to Delhi, and slightly disorganised the Congress by arriving late on account of the weather at the start. Consequently the opening ceremony was postponed a day. It was held in the grounds of the University of Delhi, and there was a very large attendance, including many prominent members of the Government of India. In addition to the presidential address, there was an address of welcome by Sir Maurice Gwyer, the vice-chancellor of the University, and other speeches were made and letters of goodwill presented, including one from Sir Henry Dale as president of the British Association.

On the following day there was the ceremony of laying the foundation stone of the new National Physical Laboratory by Pandit Nehru. This is to be built on a large vacant site not far from New Delhi, and near the already existing Agricultural Research Institute. It was a great pleasure to me personally to witness this scene since, when Sir Shanti Bhatnagar led a mission to Great Britain a year ago, he had told us much about his plans for a laboratory to parallel our own N.P.L. In a country like India, where industrial development is rather young, there is great need for a centre which can look after standardization, and this will probably be the main activity of the new Laboratory at the start, though it very properly intends to undertake a good programme of research as well. On another day we attended a ceremony when the foundation stone was laid of an Institute of Industrial Research, which is to be an organisation on something of the lines of the Mellon Institute in Pittsburg. It has been established through the generosity of Sir Shri Ram as an independent institution, and lies in grounds next the University. Yet another ceremony we attended was the conferment by the University of Delhi of honorary degrees. Lord Wavell, who is chancellor, made a great impression by speaking in Russian when he conferred degrees on the Russian delegates.

With these engagements and with much hospitality given to us, it was not easy for the visitors to attend the sectional meetings with any diligence. Each evening some of us gave lectures on general scientific subjects to audiences of something like two thousand, and we were much struck by the interest and enthusiasm of these audiences, and the notable absence of the restlessness which would be expected among such a large number. Most of us also gave papers in the sections, but it was not possible to attend the meetings regularly, and for the rest it is only possible to record general impressions. Of mathematical studies the most flourishing is statistics; including theory and application, there were no less than fifty-three contributions on the subject. Of the distinction of the many workers in physics it is scarcely necessary to speak, though reference should be made to the newly established institute in Bombay under the direction of Prof. H. J. Bhabha. In experimental physics it is refreshing to see what a lot of important work can still be done outside the nucleus. Some of us have felt there was a danger that all interest had disappeared in general physics, even including in the term the atomic physics which flourished fifteen years ago, and it is reassuring to see such a good list of titles in the subject, leaving no doubt of what a lot of interesting work there still is in it. Of other subjects I cannot claim personal knowledge, but from colleagues I have gathered that in the biological sciences the emphasis has been more on the systematic and taxonomic side, rather than on the physiological. This is perhaps natural and proper, since the fauna and flora of India must still repay closer study than they do in an intensely explored region like Europe. On the side of practical developments in scientific agriculture the outlook is most promising, though in that field there is the opposition of the intensely conservative traditions of peasant agriculture.

During the week of the Congress there was an Exhibition of Scientific Instruments in the buildings of the University of Delhi. Part of this was contributed by the Army, which showed much [illegible] the equipment it had developed for tropical warfare. One aspect shown was the damage done to military stores by various pests, both fungi and insects, and the methods of coping with it. The damage was enormous in quantity; for example, the termite is usually regarded as one of the chief tropical pests, but its damage did not rank very high in the list compared to certain beetles. There was an exhibition by the Meteorological Office of instruments and also of its methods of giving warning of flood or storm.

The chief items, however, were the manufacturers' exhibition of instruments. Before the War, scarcely any scientific instruments were made in India, but now quite a large number of firms are making them. There was a considerable variety of laboratory equipment, most of it the ordinary equipment suitable for students' laboratories. For a start this is clearly appropriate, since the demand for it is so large; but to judge by the workmanship it will not be long before more ambitious plans are made.

At the end of the Congress the visitors were taken by air to Agra for a day of sightseeing of the Taj Mahal and the other wonderful monuments near by. After this they dispersed all over India, especially to Calcutta, Bombay, Hyderabad, Bangalore and Lahore, to visit scientific institutions or to give lectures, and they then returned home separately. Since on my previous visit I had not seen the Punjab, I this time visited Lahore, which is the headquarters of the very large University of the Punjab, with its colleges spread over various parts of the province. Here I also had the good fortune to see something of the works of irrigation, including the hydraulic laboratory at Lahore and a field laboratory for hydraulic models at Madhopur, a hundred miles away. The development of hydraulics, both in experiment and practice, has in India reached a level beyond what we have yet achieved in Britain, as is witnessed not only by these laboratories but also by the actual irrigation works. In flying through Sind one goes over literally hundreds of square miles of intensively cultivated country now watered by the Indus which thirty years ago was a complete desert. In the Punjab the irrigation has been going on much longer, and they are now preoccupied with its less encouraging sides, the increasing salinity of the soil and the waterlogging.

From Lahore I went to Peshawar to see the north-west frontier. Though strictly speaking it is a digression from the subject of this article, one item of my visit may be mentioned, which is of metrological (or perhaps anthropological?) interest. Not far from Peshawar there is tribal territory which is not under the direct control of the Government of India. Here the blood-feud prevails and has called into existence a flourishing industry of rifle manufacture. The factory I saw must have had sixty or seventy workmen working with hand-driven lathes and hand-blown furnaces making rifles and revolvers which are exact copies of the British army types. They are expected to be so exact that they must be stamped with the appropriate marks, "V.R.", "Enfield", etc. The shaping is also accurate; for example, the block of metal for the chamber is filed by hand to match a template, though I confess it seemed to me that the match was visibly not quite perfect. The gun-sight was very accurately aligned with the barrel, but I could not find out how this was done. They showed me how the bore was measured during the work in a very simple manner, by pushing a conical bullet in at the muzzle so that the distance it went in gave an accurate indication of the diameter. Even the screws in the stock were hand made, but with the help of a set of taps acquired from England. The chief fault of the rifles, I was told, was that the heat treatment of the barrel could not be controlled, so that the life of the rifle was rather short; but since ammunition is hard to come by this is not so serious. I was told that it takes a man about a month to make a rifle.

For purpose of record it may be of interest to give a list of the various visiting delegations:

Britain. Prof. P. M. S. Blackett, Prof. W. Brown, Sir Charles Darwin, Sir Arthur Fleming, Prof. Munro Fox, Sir Harold Spencer Jones, Prof. L. J. Mordell, Prof. Dudley Stamp, Sir D'Arcy Thompson.

Canada. Dr. W. F. Hanna, Dr. T. L. Tanton, Prof. R. B. Thomson.

China. Prof. S. S. Chen.

France. Prof. and Mme. J. S. Hadamard.

U.S.A. Dr. A. F. Blakeslee, Dr. W. E. Deming, Dr. E. Newton Harvey, Dr. O. Riddle, Dr. Harlow Shapley.

U.S.S.R. Prof. Bolshaikov, Prof. E. N. Pavlovsky, Prof. S. Umarov, Prof. V. P. Volgin.

STRUCTURE OF CLAY

By Prof. NILS HAST
Kungl. Tekniska Högskolan, Stockholm

Methods of Investigation

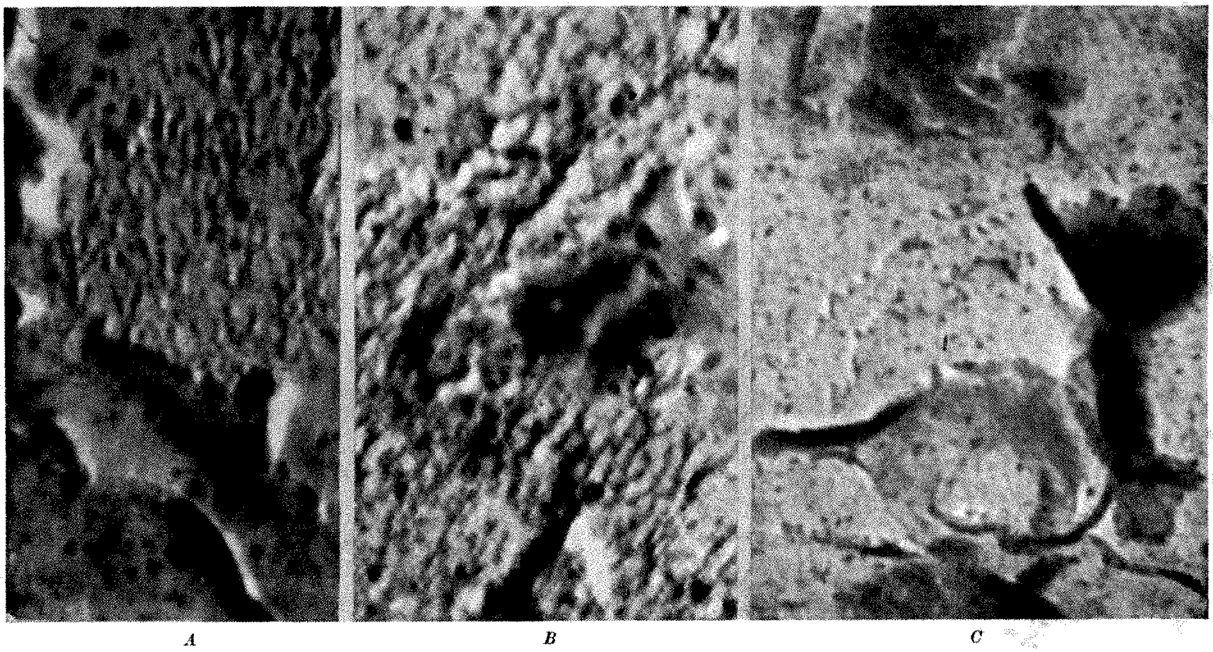
Electron-microscopical studies on clays are generally performed by suspending the clay particles in water and transferring them to the specimen film in the microscope. By this means, however, it is impossible to gain insight into the structure of the clay, since this is broken down in the suspension process.

In studying the structure of clay, I have worked out and used the experimental procedure described below. The electron microscope used is that of the Nobel Institute for Physics, Frescati, Stockholm, at which Institute the investigations are at present in progress.

A fresh fracture surface is prepared in the clay by breaking a small piece of the material in a direction perpendicular, or parallel, to the natural direction of stratification. On this surface are spread immediately some drops of a liquid with a surface tension lower than that of water, for example, amyl acetate. This liquid then covers the moist surface of the clay, entering even the slightest irregularities. If, for example, cellulose nitrate has been dissolved in the amyl acetate, the evaporation of the solvent will leave a thin film of cellulose nitrate on the clay surface. This skin, which constitutes in some measure a cast of the surface, can afterwards be peeled off.

The molecular dimensions of cellulose derivatives, polystyrene and other suitable casting preparations are, however, so large in relation to the fine structure of the clay that a cast of the finest details cannot be made with their aid. As will be shown below, the structure of clay contains details measuring 15 A. or less, which is less than the molecules in the casting material. It is also known with respect to films of the materials mentioned that they possess structures of their own, which may render the interpretation of the photographs more difficult when very high magnifications of about 100,000 must be employed, as in the case of clay.

The present procedure is based on the idea that the projecting irregularities of the clay surface are surrounded with the 'casting material' and accompany the latter when it is peeled off, but that at other parts of the fracture surface also there is a certain adhesion between the cast and the clay. When the film is removed, a fracture may take place in the actual boundary layer, for example, if water



A B C

Fig. 1. BENTONITE, FROM KINNEKULLE, SWEDEN (UPPERMOST LAYER BUT ONE IN THE CHASMAPS SERIES)

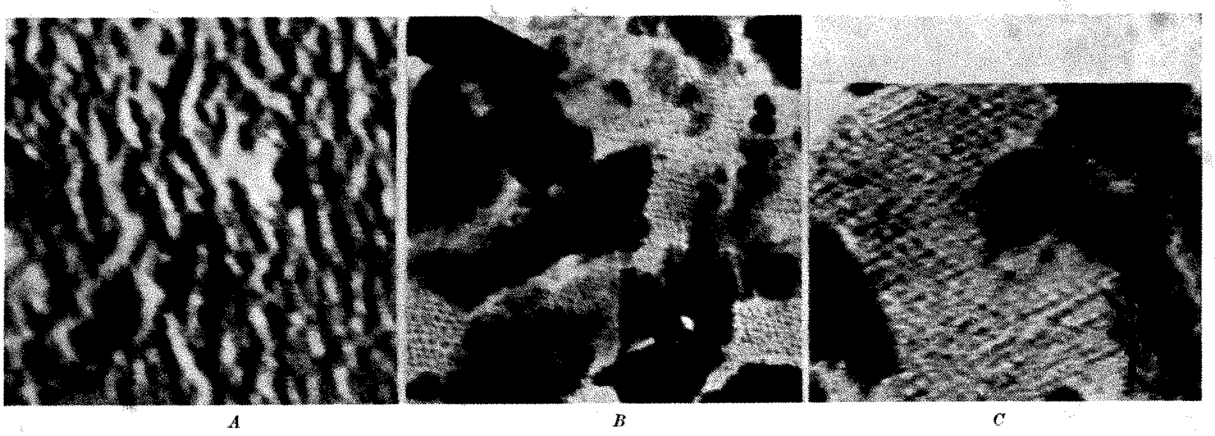
A. Section perpendicular to the direction of stratification. In the fracture surface pile-like formations appear with a diameter of about 120 A. Some of them appear to have been broken during the preparation of the specimen. Both in the piles and in other parts shown in the photograph there can be observed a distinct lined structure parallel with the natural direction of stratification in the material. The photograph also shows the tendency of the material to split up into layers. × 70,000

B. Preparation as in Fig. 1. The piles and stratum structure are plainly visible. On the right of the photograph slight indications are seen of the piles in the 'scales'. × 64,000

C. The turning up of the outer parts of the split-up thin flat pieces ('scales') are clearly visible, causing a very pronounced absorption of the electron radiation. The apparently round crystals of which the montmorillonite seems to be built up can be seen lying flat on the surface. The object film prepared according to Method 1 gives excellent diffraction patterns indicating that the bentonite used consists of fairly pure montmorillonite

covers the surface of the clay ; but the fracture will often be situated somewhat within the clay in a region where the cohesion in the structure is at its minimum. The layer of clay removed in this manner will in some places be so thin as to permit direct observation of the structure undestroyed, provided that the supporting film is sufficiently transparent. The film must be fairly thick, however, in order to be peeled off, and will consequently be opaque. This film is used to fix the thin layer of clay, so that the structure of the clay will not be deformed during the subsequent preparation. The following technique is employed to make possible the desired observations of the clay structure.

The peeled-off film of cellulose nitrate with the accompanying particles and thin surface-layer of clay are introduced into a vacuum and coated with a very thin deposit of vaporized beryllium or aluminium 25–50 A. thick. The cellulose nitrate is then dissolved away with the aid of amyl acetate.



A B C

Fig. 2. CLAY, FROM VASBY, SWEDEN

A. A lined structure is clearly visible. The dark lines represent stratification layers, as a rule two or three atomic layers in thickness. They are separated by lighter lines—actually holes produced by layers having been withdrawn in the preparation process and accompanying the other fracture side. In the photograph are also seen dark piles, and between them are holes left by withdrawn piles, leaving, however, as has been mentioned, some layers unbroken which appear as the lined structure in the picture. × 70,000.

B. Fracture configuration of a thin layer of clay. Two axes can be discerned at an angle of about 60° to each other and lying symmetrically in relation to the direction of stratification, also seen in the photograph. × 53,000.

C. Fracture surface similar to that in *B*. × 83,000.

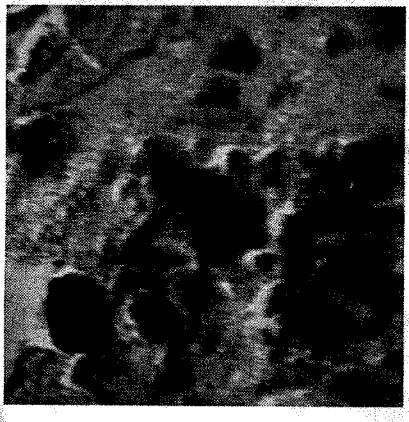


Fig. 3. CLAY. Section perpendicular to the direction of stratification. The holes left by the withdrawn single crystals are clearly visible. The width of the holes is about 120 A., but may also be double that or more. The depth of the holes corresponds to one or more atomic layers with the water layers between. Clearly marked lines with a thickness of less than 15 A. have been measured on the exposed plate. × 60,000

The removed layer of clay will remain adhering to the liberated metal film. The dissolution of the 'casting material' from the sample should preferably be carried out when the sample is placed on a specimen holder designed for direct introduction into the electron microscope for observation.

If the surface of the clay (or of any other material under investigation) has a fibrous or a porous structure, the solution of cellulose nitrate, or any other suitable solution being used, will penetrate to some depth. When the preparation is made in the way mentioned, a threadlike surface structure may be observed in the electron microscope with the threads in unaltered positions, precisely as if an extremely thin layer of the material had been cut off and transferred to the specimen holder.

As the deposited metal obviously cannot be of the same thickness at all points, one might have reason to fear that this would cause distortions in the photographs. This, however, does not appear to be the case if the film is very thin. (A photograph has been taken of a clay specimen, the thickness of the metal film being 25 A. Afterwards another 25 A. of aluminium was evaporated on the other side of the particles of the specimen and again the same part of the specimen was photographed. No details which were not visible before could be detected.) Even minute details in the clay structure prove to offer greater resistance to the electron radiation than does a beryllium or aluminium film of the minimal thickness in question. If, on the other hand, metals heavier than beryllium (or aluminium) are deposited, or if the beryllium (or aluminium) films employed are not exceedingly thin, the photographs will be distorted, and the finest details of the clay structure can no longer be detected.

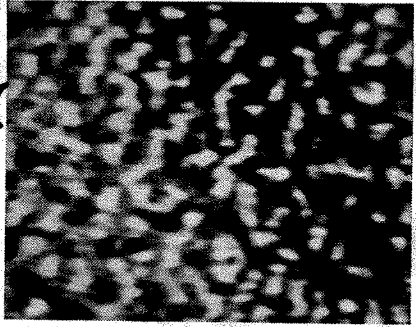

Fig. 4. FROZEN CLAY, from Väsby. The structure is in three dimensions. × 40,000

The clay surfaces have not been prepared with cutting tools, for fear that the surface structure would thus be destroyed or that water from internal cavities in the clay would spread over the surfaces. Even in the present method of breaking the clay, the coarse structure is somewhat deformed. In order to avoid this, experiments were made in which the clay samples were frozen before breaking. The frozen water stabilized the clay structure while the sample was broken off, and the structure appeared in a less deformed state in the pictures.

Other Casting Materials and Methods

In addition to cellulose nitrate as a base for the deposition (Method 1), other casting materials have been employed, largely with the aim of checking that the structure of the withdrawn film, dissolved away after the deposition of metal, does not appear in the final sample. With polystyrene, for example, the same picture of the clay and bentonite structure has been obtained as with cellulose nitrate.

Mention may also be made of the following method, intended to facilitate the reproduction of the clay structure without risk of including the structure of the casting material itself (Method 2). The film of cellulose nitrate, etc., withdrawn from the clay surface is laid, with the clay particles downwards, upon a very thin metal film (20–50 A.) on a specimen holder. The cellulose acetate is dissolved away with great care, for example, with amyl acetate. The surface layer of clay then lies on the specimen film. It is possible to do this in a satisfactory manner only if a drop of liquid is placed between the object film and the particle side of the cellulose nitrate film, the drop being evaporated before the procedure of dissolving begins. If the object film is very transparent, even the finest details in the clay structure may be observed directly. The procedure employed in preparing such extremely thin specimen films with low absorption will be described elsewhere (see p. 370 of this issue of *Nature*).

Structure of Clay

The composition of clay varies greatly according to the site of its occurrence. It usually contains substances belonging to the kaolinite and montmorillonite groups in addition to mica-like materials. As montmorillonite is identical in chemical composition with the mineral bentonite, the structure of the latter has been studied in parallel with that of clay by Methods 1 and 2. It has been found that the structure of bentonite observed in this manner is also found in a certain part of the clay material, apparently montmorillonite, which surrounds and binds together the other crystalline particles in the clay.

Photographs of bentonite and clay which I have examined seem to point to the conclusion that the montmorillonite is entirely built up of small, plane crystals—apparently round 'plates' about 120 A. in diameter. It seems likely that the plates are in fact hexagonal, though too small to be studied in detail. Their thickness seems actually to tally with that found by Hofmann and other investigators with the aid of X-rays (about 10 A.). The plates are

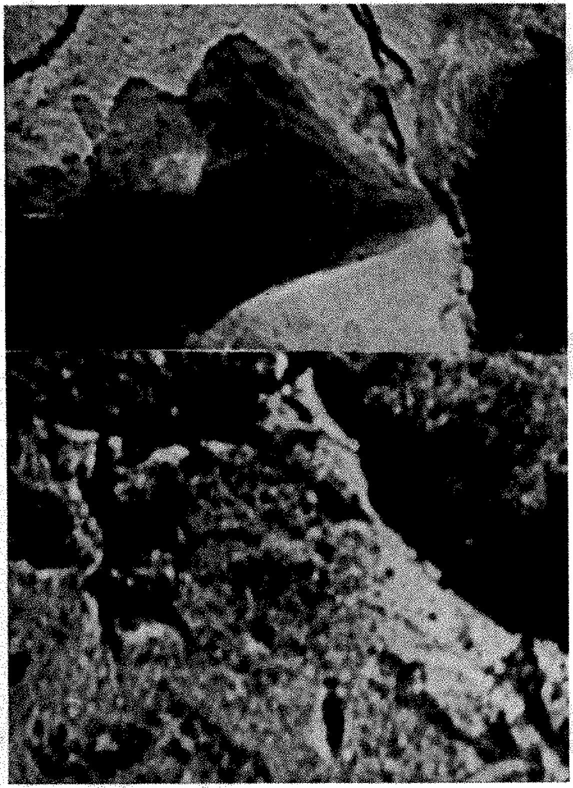

Fig. 5. MONTMORILLONITE. The layer is so thin that the structure system is visible, though in three dimensions. Upper picture, × 80,000; lower picture, × 40,000

placed one upon the other, but with a slight displacement of each in relation to the one beneath it, in a manner similar to that observed in kaolinite, and form piles, sometimes resembling threads. In a fracture of montmorillonite perpendicular to the natural stratification, these piles appear raised. Sometimes, especially when the layer of the clay removed is very thin (Method 1), figures of a regular form are to be seen in the fracture, indicating that the small crystals or plates may have regular positions in the direction of stratification. In this case it is possible that the plates are arranged in hexagonal nets, often not regular, as may be seen in some photographs, forming channels or cavities in the montmorillonite. The above-mentioned piles of plates, showing slight undulations, constitute the walls of these cavities.

The peeled-off thin layer of clay, bentonite, etc. (Method 1), has been produced on fractures perpendicular to, as well as on fractures parallel to, the natural direction of stratification.

If the montmorillonite is built up in the way suggested, that is to say, of piles of crystals with a comparatively slight force of adhesion between them, it will split into thin, flat pieces, somewhat like scales, whenever the preparation is made (Method 1) on a fracture perpendicular to that of stratification. The *C*-axis of the small crystals will then be parallel to the plane of the photograph. If the 'scales' are thin enough, the piles will be fairly clearly visible. Sometimes the 'scales' do not remain plane, their outer parts turning up and showing a very marked propensity to absorb electrons, but this effect may also depend on a variation in the thickness of the scales. In this particular the aspect is very similar to that observed when bentonite is suspended in water.

In the preparation of the clay surface and the removal of the cellulose acetate film, some of the 'plates' in the piles would appear to accompany one side of the fracture and some the other. The consequence is that line structures appear in the casts, these being holes left by withdrawn 'plates'. The thickness of the lines generally shows that they must represent two or more atomic layers together with the water-layers lying between. Occasionally, however, lines are observed that cannot be estimated as exceeding 15 A. in thickness. These suggest the cavities left by single atomic layers, with their attendant water-layers, withdrawn from the pile. That such narrow lines can be observed with such sharpness is due to the fact that the objects reproduced are layers seen edgewise, or cavities between such layers, with a depth of absorption some ten times greater than the width of the lines. The method should be capable of further development as a means of determining the resolving power of the electron microscope.

ATMOSPHERIC OSCILLATIONS*

THE theory of the tides is one of the many offshoots of Newton's theories of mechanics and of gravitation. Much of the later development of these theories was achieved by the great French school of mathematicians, and the first important steps in the theory of the atmospheric tides were made by Laplace (1774) and later described in his "Mécanique Céleste". He also was the first to attempt to determine the lunar atmospheric tide from barometric observations; he realized that tropical data were the most suitable for the purpose, but lacking them, he used 4,752 readings at Brest. His result, as he recognized, did not give the true tidal pressure variation at Brest, which is too small to be separated, in such a short series of data, from the solar daily variations and the much larger irregular changes associated with the weather.

The Lunar Atmospheric Tide

The lunar atmospheric tide was first determined in 1842 by Lefroy from bihourly barometric readings over seventeen months at the British Colonial Magnetic and Meteorological Observatory at St. Helena (16° S.). Smythe, Sabine and Elliot extended the analysis at St. Helena, and also determined the tide at Singapore. Several of the gifted directors of the Netherlands Government Observatory at Batavia (6° S.) made valuable determinations there, as their barometric data accumulated.

These successes were possible because in the tropics the lunar atmospheric tide has its greatest amplitude, while the irregular variations there are less than elsewhere (except during extreme cyclonic conditions). Further attempts to determine the tide in temperate latitudes by Bouvard, Eisenlohr, Neumayer, Airy (using twenty years hourly observations at Greenwich), Börnstein, Morano and others proved unsuccessful, until 1918, when Chapman made a determination for Greenwich, where observations covering sixty-

* This article summarizes a Geophysical Discussion held at the Royal Astronomical Society on January 24, under the chairmanship of Sir Edward Appleton. The Discussion, which was opened by Prof. Sydney Chapman, was continued by Sir Geoffrey Taylor, Dr. M. V. Wilkes and Mr. K. Weekes.

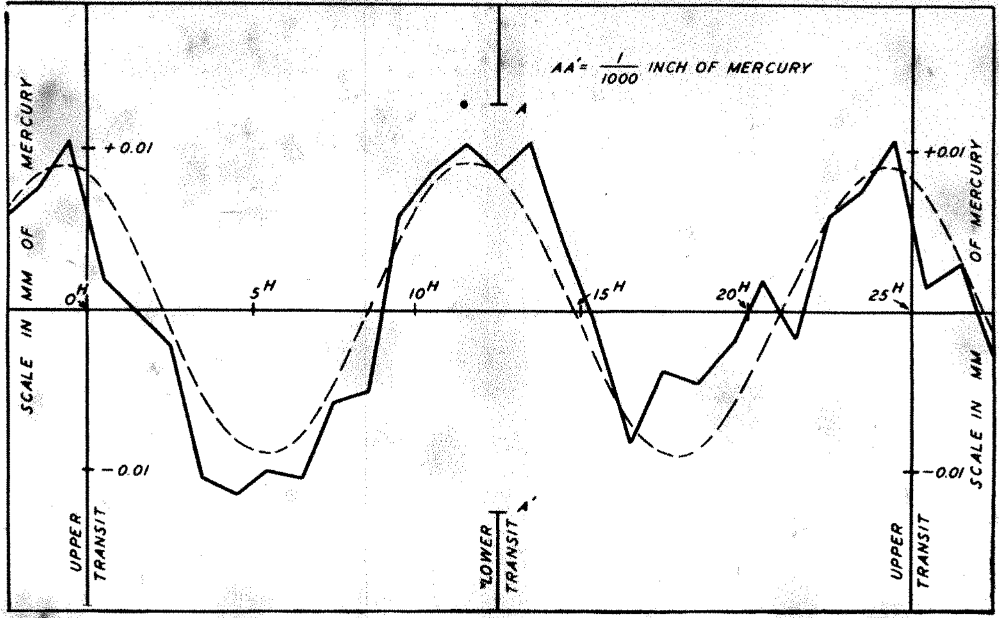

Fig. 1. THE LUNAR TIDAL BAROMETRIC VARIATION AT GREENWICH; ——, CURVE CALCULATED FROM THE HOURLY BAROMETRIC OBSERVATIONS; – – –, SEMI-DIURNAL COMPONENT OF THE CALCULATED CURVE

three years were by then available. Two thirds of the data were discarded, only those days being used on which the barometric range did not exceed 0·1 in. of mercury. Moreover, the last digit of the readings (made to 0·001 in.) was discarded. It was a remarkable illustration of the law of errors that the data, thus used only to 0·01 in., disclosed a lunar semi-diurnal variation of pressure (Fig. 1) of total amplitude less than 0·001 in., the average change from hour to hour being of order 0·0001 in.

Since 1918 the number of determinations of the lunar atmospheric tide has greatly increased, its present value being about fifty-four (forty-four in the northern hemisphere, ten south of the equator; fifteen tropical, thirty-nine in higher latitudes). Bartels has obtained three of these, Pramanik also three, Robb and Tannahill one, most of the others having been derived by Chapman and his colleagues at the Imperial College of Science and Technology, where the speed of the work was greatly increased after 1930 by the generous loan of a set of Hollerith machines by the British Tabulating Machine Company, Ltd.

Some of the results are summarized in Fig. 2, which shows a number of arrows on a Mercator map of the world. Each arrow represents in length (on the scale indicated) the semi-amplitude of the lunar tidal variation of the barometer at the place situated at the *centre* of the arrow; if the arrow is regarded also as the hour hand of a clock that keeps lunar time (so that the northerly direction on the chart would correspond to 12^{h} lunar, that is, upper or lower meridian passage of the moon), then the direction of the arrow indicates the time of maximum barometric pressure, or atmospheric high tide (lunar).

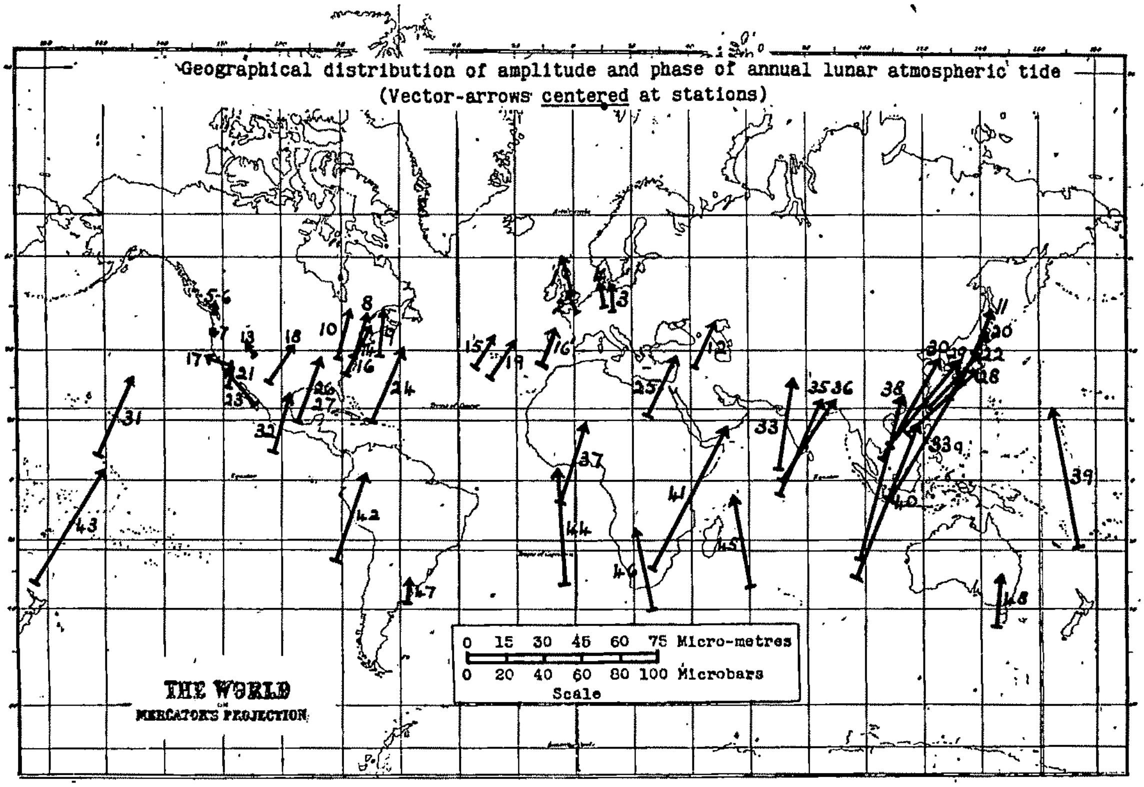
The chart shows that at most of the places considered the time of high tide is after lunar transit, by about 45 min. in the northern hemisphere, and 20 min. in the southern, where, however, there are large gaps in our knowledge; but there are stations where the tide is certainly early, before the moon's passage, namely, Mauritius (No. 45 on the chart) and Kimberley (No. 46). The tide is greatest in the tropics, but the decrease with increasing latitude is not regular: places in the same latitude may have decidedly different air-tides; for example, Buenos Ayres (47) and Melbourne (48). These irregularities are perhaps surprising, as the atmospheric ocean is not complicated by lateral boundaries.

The lunar atmospheric tide seems to vary in amplitude from apogee to perigee, with the changing distance of the moon, in much the way that tidal theory would suggest. But it has an unexpected variation also throughout the year, which is not seasonal, as it does not change when the sun crosses the equator; over most of the earth the tidal range is greatest at the June solstice; near the December solstice the lag after the moon is most pronounced, being more than half an hour later than the annual mean hour of tidal maximum. This change of the tide throughout the year still awaits an explanation.

Solar Daily Oscillations

Though in the oceans the daily changes of level are due primarily to the moon, in the atmosphere this is not so. The main periodic oscillation is solar semi-diurnal, with maxima in barometric pressure at about 10 a.m. and 10 p.m. local time. This is shown clearly in tropical barograph records, of which it is the main feature, except when hurricanes pass the station. In temperate latitudes it is obscured by the far larger irregular changes of pressure, but it is easily determined by averaging the data of many days.

Though the phase of this 12-hour (solar) wave in the barometric variation is remarkably constant over the belt between ± 50° latitude, with increasing latitude the oscillation tends to vary with *absolute* time, as first perceived by Greely. Through the work of Schmidt, Alt and Simpson, it has been shown that there are *two* solar semi-diurnal oscillations, one of tidal type, following the sun (and anti-sun) round the earth, the other being symmetrical about the earth's axis, and consisting of a 'zonal' oscillation of air between the equator and the poles. Simpson found that the corresponding two terms in the barometric variation are:



Geographical distribution of amplitude and phase of annual lunar atmospheric tide
(Vector-arrows centered at stations)
0 15 30 45 60 75 Micro-metres
0 20 40 60 80 100 Microbars
Scale
THE WORLD ON MERCATOR'S PROJECTION

Fig. 2

$$0{\cdot}937 \cos^3\varphi \sin(2t + 154^\circ) \text{ mm. of mercury}$$
$$\text{and } 0{\cdot}137(\sin^2\varphi - \tfrac{1}{3}) \sin (2t + 105^\circ - 2\lambda) \text{ mm.,}$$

where φ denotes the latitude, t the local mean solar time reckoned in angle at the rate 15° per hour, and λ denotes the longitude east of Greenwich. Thus at the equator the amplitude of the zonal part of the semi-diurnal oscillation is only 0·046 mm.

The solar 12-hourly oscillation, like the lunar tide, has an annual variation, mainly not seasonal; in phase the change is opposite to that for the lunar tide, the maximum pressure occurring earliest in December and latest in July or August. The amplitude varies less than in the case of the lunar tide; at many places it has two maxima in the year, near the equinoxes, and two minima near the equinoxes.

In addition, there is a fairly regular world-wide oscillation of period 8 (solar) hours, represented approximately in the barometric variations by a term of amplitude $0{\cdot}46 \sin\varphi \cos^3\varphi$ mm. in December; the phase is nearly opposite in the two hemispheres, and is nearly reversed from summer to winter.

Theory of the Oscillations

As Sir Geoffrey Taylor pointed out in the discussion, Laplace showed that in an *isothermal* atmosphere, oscillations involving no vertical motion, and in which the changes of volume occur *isothermally*, have the same free periods as those of corresponding mode (or geographical distribution) in a liquid ocean of a certain equivalent depth, which is actually the height of the equivalent homogeneous atmosphere. Margules developed the theory along these lines, stimulated by a hypothesis proposed by Kelvin, to explain why the solar semi-diurnal atmospheric oscillation so much exceeds the lunar (the ratio at the equator being about 15 to 1). Kelvin concluded that the former is of thermal origin, and that it is much magnified by resonance with a free period of atmospheric oscillation, of the same mode, very nearly approximating to 12 solar hours. Margules confirmed Kelvin's resonance hypothesis by finding a free period nearly coinciding with half a day. But this confirmation was unreliable, because the atmosphere and its oscillations are not isothermal, as Laplace's theory and Margules' calculations postulated.

Lamb investigated the horizontal propagation of plane waves in a non-rotating atmosphere on more realistic assumptions, taking into account vertical motion and adiabatic oscillations, but not the observed temperature-distribution with height. He then assumed that free oscillations of the atmosphere can exist which are identical in mode and period with those of an ocean of such depth that long waves are propagated in it with the speed that he calculated for plane waves. This assumption, which may be regarded as an extension of Laplace's theory of waves in an isothermal atmosphere, is not obviously true, since it involves the possibility that the atmosphere may have many equivalent depths, a contingency which is not possible in the case of an isothermal atmosphere. Lamb's assumption was later proved to be true by Taylor, who had used it previously to estimate the period to be expected in an atmosphere capable of carrying waves propagated at the speed observed in those produced by the Krakatoa volcanic eruption in 1883; Taylor concluded that the atmosphere has no free motion with a period so close to 12 hours as to fit Kelvin's resonance hypothesis. Later, however, he developed Lamb's work on oscillations having similar ground distributions but different height distributions of motion, taking account also of the cessation, at the tropopause, of the upward lapse of atmospheric temperature. Soon afterwards Pekeris applied Taylor's methods to determine the free periods of an atmosphere in which the stratospheric temperature again begins to increase upwards (as indicated by the abnormal propagation of sound to great distances) and then, still higher up, decreases once more. He showed that such an atmosphere could have a free oscillation of tidal type with a period very close to 12 hours, though the uncertainty of the upper atmospheric data as yet preclude the exact calculation of the period.

Tides in the Ionosphere

The calculations by Pekeris indicated that the amplitude of his free oscillation of nearly half-day period would increase greatly with height. Soon afterwards, Appleton and Weekes announced the astounding but well-authenticated discovery of a lunar tidal twice-daily rise and fall of the *E* layer of the ionosphere by nearly ± 1 km., indicating an enormous magnification of the lunar tidal oscillation at high levels, as compared with the ground.

The study of the lunar daily geomagnetic variations had already shown the existence of the lunar tide in an electrically conducting layer of the atmosphere, reasonably to be identified with the ionosphere. The theory of these variations was in some ways rendered easier by the discovery of the large tide in the *E*-layer, which lessened the rather difficult demands made by the theory on the conductivity of the layer. The *E*-layer tide, however, was in phase with the moon, whereas the magnetic variations indicate an oscillation of opposite phase.

New Calculations of the Forced Oscillations

This interesting and complex situation as regards the facts and the theory of the atmospheric oscillations and their ionospheric effects calls both for further observations (in particular, as to the thermal structure of the atmosphere up to ionospheric levels) and renewed theoretical studies of the oscillations. Dr. M. V. Wilkes and Mr. K. Weekes described their new studies of this kind. The main input of tidal and thermal energy into the atmospheric oscillations is near the ground; energy passes upwards from thence, as if propagated in a medium with refractive index μ given by

$$\mu^2 = -\frac{1}{4} + \frac{1}{h}\left(\frac{\gamma - 1}{\gamma} H + \frac{dH}{dx}\right),$$

where γ is the usual specific-heat ratio, x is a co-ordinate depending on the height, H the scale height ($RT/\overline{m}g$) and h the equivalent height of the ocean with the same free period for the type of oscillation considered. If the distribution of temperature T (or $T/\overline{m}$, where $\overline{m}$ denotes the mean molecular weight) makes μ^2 negative at a certain layer, this acts as a barrier against upward propagation, like a total reflector, and resonance may occur. Using this method of approach, it is possible to see on general grounds that if the resonance theory is accepted the temperature in the atmosphere must be assumed to fall again (for example, to 200–240° K.) above the first hot layer in the stratosphere. The boundary condition applied at high levels is that the flow of energy is upward. The energy is finally lost in the region above 150 km., where the kinematic viscosity becomes so great as to cause heavy damping of the waves.

Mr. Weekes described the strenuous efforts made to find temperature–height distributions consistent with the high resonance of the solar half-daily oscillation at the ground, and of the lunar tidal oscillation in the ionosphere. Taking the stratospheric temperature to rise from 220° K. to 400° K. in the layer between 33 and 45 km. height, and then to fall to 200° K. (as suggested by the work of Ratcliffe, Budden and Wilkes on the propagation of long radio waves), the oscillation at about 100 km. was found to be reversed, agreeing with the indications of the lunar tidal geomagnetic variation. This reversal of phase at high level, which was first found by Pekeris, is in contradiction to the experimental results of Appleton and Weekes. Further calculations have shown, however, that this discrepancy is not a fundamental one and can be resolved, for example, if the temperature is assumed to rise again to a further maximum in the *E* region.

It may be expected that in the fairly near future the temperature–height distribution in the atmosphere will be actually measured by V2 rocket methods. This will remove much that is now tentative in the theory of these atmospheric oscillations; but it remains to be seen whether the many pieces of evidence will then combine to form a clear co-ordinated picture, or whether discrepancies will persist and call for further search and effort.

S. CHAPMAN

HISTORY AND WORK OF THE PALÆONTOGRAPHICAL SOCIETY

MARCH 23 marks the hundredth anniversary of the foundation of the Palæontographical Society, the only Society which devotes all its resources to the illustration and description of British fossils. Members will celebrate this centenary of scientific work by holding the hundredth annual general meeting on the morning of Monday, March 31, when the present president, Prof. H. L. Hawkins, professor of geology in the University of Reading, will deliver a commemorative address; in the afternoon, a public lecture will be delivered in the lecture room of the Geological Survey Museum, and in the evening, members will dine at the Hall of the Worshipful Company of Tallow Chandlers, Dowgate Hill, London.

Several years before the foundation of the Society, a group of seven enthusiasts had common interests in the study of Tertiary fossils, and acted together under the name of the London Clay Club; for the most part, their rich collections of fossils passed eventually to the British Museum (Natural History). The leading spirit of this club was J. S. Bowerbank (1797–1877), a well-to-do London distiller, keenly interested in many sciences, who in 1839 was one of the founders of the Royal Microscopical Society. The other members were F. E. Edwards (1799–1875), a solicitor; John Morris (1810–86), then a Kensington pharmacist; J. de C. Sowerby (1787–1871), a naturalist who was continuing the illustration and publication of the "Mineral Conchology" started in 1812 by his father, J. Sowerby; N. T. Wetherell, M.R.C.S. (1800–75), of Highgate; S. V. Wood (1798–1880), a retired officer of the Merchant Navy; and Alfred White. The members of this Club contributed papers to the learned societies and periodicals, and occasionally unique fossils from their collections were illustrated and described in the "Mineral Conchology"; this publication, however, with its 649 hand-coloured octavo plates issued over thirty-seven years in 113 instalments, had no particular systematic arrangement; furthermore, it was waning in frequency of appearance, and between 1835 and 1845 only thirty-nine plates were published. In 1845 its publication ceased; and in the following year, G. B. Sowerby and Son issued a fly-leaf inviting subscriptions for the first number, price five shillings, of a royal quarto publication to be called "Fossils of the British Strata Illustrated and Described" and to be issued on January 1, 1847, and on the first day of alternate months. The first works promised were fossils of the Crag (shells and other invertebrates by S. V. Wood, Echinodermata by E. Forbes), also fossils of the London Clay (shells by F. E. Edwards, Echinodermata by Forbes). A specimen plate of the Crag fossils was exhibited at the British Association meeting held in September 1846 at Southampton. The publication did not materialize on January 1, 1847, but the concept grew and the promised works appeared later; for, on February 3 of that year, during the tea following the reading to the Geological Society of J. Prestwich's paper "On the Probable Age of the London Clay and its Relation to the Hampshire and Paris Tertiary Systems", with the collaboration of Edward Forbes, palæontologist to the Geological Survey, Bowerbank "solicited the leading geologists present to support him in establishing a Society for the publication of undescribed British fossils" (*Geol. Mag.*, 192; 1877).

As a sequel, a meeting was held on March 23, 1847, in the Geological Society's apartments, then in Somerset House, to establish a Society, "to figure and describe as completely as possible a stratigraphical series of British Fossils". The chair was taken by Sir Henry De la Beche, director of the Geological Survey and president of the Geological Society. The new society was named the Palæontographical Society, and it was resolved that an annual subscription of one guinea, paid in advance, on the first day of January each year, entitled a member to the publication issued by the Society for that year. The business was to be conducted by a president, treasurer, secretary and sixteen members of council to be elected annually at a general meeting. The foundation resolutions are still adhered to by this Society, and the Geological Society continues to offer the hospitality of its apartments for council and general meetings and for storing sales stock.

Those elected as officers and council of the Society at its inaugural meeting included several who were among the seventy-five authors of the eighty-two monographs eventually embarked upon by the Society; in the list that follows, the subjects and dates of issue of such monographs are indicated in brackets. President, Sir Henry De la Beche, F.R.S.; Treasurer, S. V. Wood (Crag Mollusca, 1848–82; Eocene Bivalves, 1861–77); Secretary, J. Morris (with J. Lycett, Great Oolite Mollusca, 1851–63). Council: Prof. T. Bell, F.R.S. (Malacostracous Crustacea, 1858–62; with R. Owen, London Clay Reptilia, 1849); J. S. Bowerbank, F.R.S., who within six weeks was elected secretary; F. E. Edwards (Eocene Mollusca, 1849–77); Sir Philip de M. Egerton, M.P., F.R.S., collector and authority on fossil fishes; H. Falconer, M.D., F.R.S., distinguished for his work on fossil mammals; W. H. Fitton, M.D., F.R.S., a pioneer in the study of the British Cretaceous and Upper Jurassic strata; J. W. Flower of Croydon; Prof. E. Forbes, F.R.S. (Tertiary Echinodermata, 1852); Capt. L. L. B. Ibbetson, who, according to Buckland, had applied a "photogenic process for rapidly producing perfect drawings of fossil shells on metallic plates from which when fixt by the engravers tool, lithographic transfers may be rapidly multiplied to an almost indefinite extent"; C. Lyell, F.R.S., renowned for his text-books and for his definition of the Eocene, Miocene and Pliocene formations; Prof. J. Phillips, F.R.S. (British Belemnites, 1865–70), with Conybeare, the first to define the Carboniferous System and its main subdivisions; J. Prestwich, authority on the Pleistocene, Tertiary and Coal Measures; D. Sharpe (Chalk Mollusca, 1853–57); J. Smith, F.R.S., of Jordanhill, Glasgow, who studied the Pleistocene; N. T. Wetherell, many of whose Tertiary fossils were illustrated in the Society's monographs, and A. White. The last surviving member of this illustrious council, Sir Joseph Prestwich, died on June 23, 1897, four days after the Society's fiftieth anniversary had been celebrated.

At early council meetings, the format of publication was adopted as quarto demy, and offers of monographs were considered; G. B. Sowerby was commissioned to undertake copper-plate engraving, and Messrs. Adlards were engaged as printers; this last engagement has been unbroken for the hundred years. Special recruiting meetings were held at the British Association meeting at Oxford in 1847 and again at the Association's meeting at Swansea in 1848, by which time Volume 1, containing the first part of S. V. Wood's "Monograph of Crag Mollusca", had been distributed to nearly six hundred members. Local secretaries, who assisted in the distribution of the volumes to members, numbered thirty-eight. As would be expected from the circumstances preceding the Society's formation, monographs dealing with Tertiary fossils were prominent in early volumes; these included a monograph by Charles Darwin dealing with fossil Cirripedes; by 1851, however, William King's "Permian Fossils" had been completed, and other major productions such as Milne Edwards and J. Haime's "Fossil Corals" and T. Davidson's "Fossil Brachiopoda" had been commenced. This last is unique among the Society's publications, since its range is from Cambrian to Pliocene; it is illustrated by drawings made on stone by Davidson himself, and it continued publication until 1885, giving description and illustration to some 960 species. Most of the monographs cover considerably shorter time-ranges; but rarely do they range below the stratigraphical unit of series.

It has been said that at the period of the Society's formation, opinion was held that the work should be ended within twenty-five years, presumably because the species then known were few. The number now described is uncounted. Morris's "Catalogue of British Fossils" in its 1854 edition listed but 8,359; by 1886, however, Etheridge estimated them at 19,022, and up to 1897 the Society was stated to have illustrated and described only some 6,988 species. Since that time, monographs current then have been finished, and twenty-five new works either have been completed or are still in progress. Several of the older as well as some of the modern monographs have had a considerable influence on both stratigraphy and palæontology; in 1899, the science's historian, K. A. von Zittel, recorded that the publications held the foremost place among periodicals dealing with palæontology. There remain, however, a few groups of fossils still virtually untouched by the Society, and certain monographs need revision; these defects are being remedied as specialists become available and willing to undertake such work. Preparation is being made for the issue of nomenclatorial supplements to early monographs, and a new monograph on Carboniferous Crinoidea is promised publication in the near future.

The Society came into being when there were many collectors anxious to identify their finds, and the membership remained between five and six hundred during the first fifty years of the Society's history; there was, however, during that time a steady rise in the proportion of library subscribers. In the first thirty years of the present century, there was a marked fall in numbers of personal members, but the figures have lately shown a slight rise. The fall in membership as well as the rise in cost of printing has resulted in a decrease in thickness of the annual volume, because it was thought desirable not to increase the original subscription rate.

The Society has had ten presidents: Sir Henry De la Beche (1847–55); W. J. Hamilton (1856–67); Dr. J. S. Bowerbank (1867–77); Sir Richard Owen (1877–92), who was responsible for eight monographs on fossil Reptilia and Mammalia; T. H. Huxley (1893–5); Dr. H. Woodward (1896–1921), who wrote three monographs dealing with Palæozoic Arthropoda, one in association with T. R. Jones; E. T. Newton (1921–28); Dr. F. A. Bather (1928–34); Sir Arthur Smith Woodward (1934–44). The treasurers have been seven: S. V. Wood (1847–80); S. V. Wood, jun. (1880–84); R. Etheridge (1884–1904); Dr. G. J. Hinde (1905–14), who wrote a monograph on fossil sponges; R. S. Herries (1914–38); W. E. F. Macmillan (1938–46). The secretaries, who also serve as editors, have been five: J. Morris (1847, for a few weeks); J. S. Bowerbank (1847–63); Rev. T. Wiltshire (1863–1900); Sir Arthur Smith Woodward (1900–34), who during this period completed two monographs on fossil fishes. The present office holders are: President, Prof. H. L. Hawkins (1944–); Treasurer, Dr. A. J. Bull (1946–); Secretary, Dr. C. J. Stubblefield (1934–).

C. J. S.

OBITUARIES

Brigadier H. St. J. L. Winterbotham, C.B., C.M.G.

Harold St. John Lloyd Winterbotham died on Tuesday, December 10, 1946, at his home at Sutton Courtenay at the age of sixty-eight. He was the second son of Canon R. Winterbotham, was born on February 5, 1879, educated at Fettes and the Royal Military Academy, Woolwich, and commissioned in the Royal Engineers in 1897. He was awarded the Queen's Medal with three clasps for his services in the South African War, and when the War ended was appointed garrison adjutant at St. Helena. After a short period of home service he returned to South Africa in 1908, where he carried out a topographical survey of the Orange Free State.

In 1911 he joined the Ordnance Survey at Southampton, where he was placed in charge of the Trigonometrical and Topographical Division. Some doubts had been expressed about the accuracy of the Principal Triangulation of Great Britain, which had been carried out about a hundred years before. It had already been decided to carry out a check, and a new base had been measured at Lossiemouth before Winterbotham arrived. He took charge of the remaining operations required to complete the check of the old work, and published an important professional paper describing the results. This indicated that the Principal Triangulation was comparable in accuracy with work carried out on the Continent by the most modern methods.

Soon after the outbreak of war in 1914, Winterbotham left Southampton for France in command of the Ranging Section R.E., a small unit intended to be used for fixing the position of an aeroplane at the instant that it dropped a smoke signal over a hostile target. This small unit was the nucleus which, in conjunction with "Maps G.H.Q.", grew into the large military survey organisation which existed in the field in 1918. In this organisation Winterbotham served first in command of the 3rd Field Survey Company and later as technical assistant to the Officer in Charge of Maps G.H.Q., with a short interval during which he was in charge of Survey at G.H.Q. Italy. For his services he was mentioned three times in dispatches, was made a C.M.G. and received the D.S.O. and the brevet of lieutenant-colonel.

In 1920 Winterbotham returned to his old post in the Trigonometrical Division of the Ordnance Survey. In 1922 he became chief of the Geographical Section, General Staff, a post which he retained until 1929. During this time he was jointly responsible with Colonel (later Sir Charles Arden) Close for the production of the third edition of the "Text-Book of Topographical Surveying", and he also published "Survey Computations", a book of great value to the field surveyor whether military and civil.

At this time a revolutionary alteration in the design of theodolites had been made on the Continent, and British models were in danger of being completely outclassed. It was on Winterbotham's initiative that a conference was called at Tavistock to consider the design of a new British instrument. This was attended by representatives of the Services and of the leading survey instrument manufacturers, and led to the production of the Tavistock theodolite by the firm of Cooke, Troughton and Simms, to the great advantage of British surveyors in the Second World War.

During his term at the War Office, Winterbotham's interest in geodesy not only led him to take an active part in the affairs of the International Union of Geodesy, but also he was responsible for sending a party to Africa to complete the geodetic observations of a section of the arc of the 30th meridian. During this time, too, he was one of the original founders of the Field Survey Association, the success of which owed much to his energy.

Following his term at the War Office he carried out an inspection of Colonial survey departments, and included in his tour a visit to the party of Royal Engineers which he had been responsible for sending out to carry out the trigonometrical observations of the arc of the 30th meridian in Africa.

In 1930 Winterbotham was appointed director-general of the Ordnance Survey, and the following year became A.D.C. to the King. His time at the Ordnance Survey was one of severe financial stringency, when establishments were cut to the bone. Opportunities for carrying out any original work, or indeed anything but routine revision, were few. Fortunately for the Ordnance Survey, Winterbotham was able to find time for a study and overhaul of old records. His most important publication at this time was "The National Plans", which gives a very complete historical description of the large-scale plans of the Ordnance Survey. His work on this and other publications came to be fully appreciated by those who had to restart the Ordnance Survey on its national work after the Second World War. With many files and records destroyed during the War and a seven years gap in the continuity of the work, the existence of those carefully prepared historical studies was an inestimable boon. In 1935, having reached the age limit, Winterbotham retired from the Army and from the Ordnance Survey. In the same year he was made a C.B.

But the energy which had so far been mainly directed to the execution of his official duties was now more fully available for that work for the International Union of Geodesy and Geophysics which had always been one of his principal interests. In the early general assemblies of the Union his professional co-operation had been much in demand by the Governments he had advised and assisted in survey work. At the third assembly in Prague (1927), we find him entrusted with the representation of South Africa, Australia and Canada, as well as the General Staff of the War Office.

Then in 1928, when Colonel (later Sir Henry) Lyons succeeded Sir Arthur Schuster as general secretary of the International Research Council and resigned the general secretaryship of the International Union of Geodesy and Geophysics, Winterbotham accepted an invitation to succeed him; and from the following assembly at Stockholm in 1930 until his death, Winterbotham's interests and enthusiasms were seldom far from the Union. There he guided and humoured successive presidents and executive committees and helped the secretaries of the constituent associations not quite so experienced or so expert in administrative matters as himself—all with a friendly kindliness which did not stop him from frank expression of opinion when he considered the real interests and welfare of the Union to be at stake.

Winterbotham's wide experience of men and affairs stood the Union in excellent stead during the war years. Immediately after the Washington assembly in September 1939, from which he was recalled for official duties, Winterbotham took steps to safeguard the international interests and widely distributed funds of the Union and of its various associations. It is largely owing to his judgment and foresight that the International Union of Geodesy and Geophysics came through the war years ready to undertake fresh international scientific work. Meanwhile he had offered his services to the Government and had been employed, first as chief instructor in survey at the School of Military Engineering, and later under the Admiralty on the preparation of topographical reports.

Before the War had properly ended, Winterbotham set about gathering together again the broken threads of international geodetic and geophysical collaboration. At a meeting of the executive committee of the Union which he was instrumental in calling together in 1945, plans were discussed for early renewal of the Union's activities. By that time, unfortunately, Winterbotham had been advised that he must take things more easily, and it was with great regret that the committee accepted his resignation. At the subsequent extraordinary assembly of the Union in August 1946, Winterbotham was honoured by election as one of the two vice-presidents of the Union under the new statutes in the framing of which he himself had spent much thought and care. By this election the assembly hoped that his ripe experience and judgment in Union affairs would continue at the disposal of the Union for many years; but, though not known to many, he was already a sick man, and he did not live to contribute still further to the Union's international prestige, which he had done so much to enhance during his long and active association with it.

There will be many people in many lands who will remember Winterbotham's sage counsel given in a characteristic and incisive style, and there will be many who will miss that counsel in the years to come. He leaves a widow, one son and two daughters.

G. CHEETHAM

Dr. C. T. Madigan

BY the death of Cecil Thomas Madigan, Australian geology has been deprived of one of its most colourful personalities, a man who throughout his entire life had retained the youthful spirit of the true pioneer and explorer. Born on October 15, 1889, the son of Thomas Madigan of Renmark, South Australia, he was educated at the University of Adelaide, where he was known as a first-class oarsman.

Although elected to a Rhodes Scholarship at Oxford in 1911, Madigan did not go into residence until 1914, in the meantime having accompanied Sir Douglas Mawson as his second-in-command on the Australian Antarctic Expedition. On the outbreak of war not long after his arrival in Oxford, he was granted a commission in the Royal Engineers, with whom he saw four years service in France, being twice wounded and gaining a mention in dispatches.

On demobilization in 1919, Madigan returned to Oxford and obtained a first-class in the final honour school of geology. While carrying out research on material brought back from the Antarctic, he was appointed assistant Government geologist in the Sudan, where he spent two years before returning to Adelaide to become senior lecturer in geology, a post he held until his death. During the Second World War Madigan again joined the Forces, and with the rank of lieutenant-colonel was chief instructor of the School of Military Engineering at Liverpool, New South Wales, for three years.

The greater part of Madigan's work was devoted to the exploration of what Gregory had aptly termed the "Dead Heart of Australia". In 1929 he made the first aerial reconnaissance of this *terra incognita*, exploring an area of some 28,000 square miles which no white man had ever seen and which had previously baffled all attempts to cross it. He proved that the great lakes were dry, and that nothing lay within the area other than clay-flats encrusted with salt and everlasting sand-ridges; having had, in his own words, the somewhat melancholy satisfaction of saving the danger and expense of further exploration.

By this and subsequent journeys with car or camels, Madigan obtained a vast amount of valuable geological and topographical information, extending as far north as the MacDonnell Ranges and the area north of Lake Eyre, which he named the Simpson Desert; and the account he has given of this most inhospitable country in numerous papers published by the Royal Society of South Australia, the Royal Geographical Society and the Geological Society of London makes the most interesting reading. Some of his remarkable aerial photographs were recently published in the *Illustrated London News* (January 25, 1947).

In 1915 Madigan married Wynnis Wollaston, by whom he had three sons and two daughters, all of whom survive him. While grieving his loss, his many friends may be comforted by the thought that one who loved the wide open spaces was spared possibly many years of enforced inactivity. He has left behind a record of service to his country of which any man might well be proud. J. A. DOUGLAS

Prof. P. J. Daniell

PROF. P. J. DANIELL, professor of mathematics in the University of Sheffield, died on May 25, 1946, at the age of fifty-seven. He was educated at King Edward VI School, Birmingham, and at Trinity College, Cambridge. He was Senior Wrangler in 1909, the last year in which the names of the candidates in Part 1 of the Mathematical Tripos were placed in order of merit. In Part 2 of the Natural Sciences Tripos in 1910 he obtained a first class, and in 1912 he was awarded a Rayleigh Prize. After studying in Göttingen for two years and then acting as an assistant lecturer at the University of Liverpool, he went to the Rice Institute, Texas, where he was professor of mathematics until 1923. In that year he returned to England as professor of mathematics in Sheffield, and held this post until his death. In the summer of 1945 he had a serious illness from which he did not fully recover, and he died about a year later after a sudden relapse.

Prof. Daniell was a distinguished scholar of pure and applied mathematics. The most important of his earlier contributions to mathematical knowledge were related to generalized integrals and derivatives. He extended the Radon–Young integral to space of an infinite number of dimensions, and his integral was applicable, for example, in the theory of functionals. He considered also generalized derivatives, using methods that were based partly on Young's work in one dimension and partly on ideas introduced by himself. His research, however, extended over a wide field of applied science, and much of his time and energy were spent in assisting and advising research workers in a variety of problems. His mathematical investigation on the propagation of flame motion, for example, was related to experimental work carried out by the Safety in Mines Research Board in Sheffield. Perhaps his most important work of this kind was that done during the War, when he was engaged in problems arising from the control of instruments designed to pick up and locate targets such as aeroplanes and ships. He assisted in the work of improving the performance of such instruments, and he was a leading exponent of the frequency response approach to the problems involved in the design of these instruments. He initiated methods in dealing with problems of back-lash, and he assisted the Admiralty in ultra-high-frequency detection methods.

In educational affairs generally, Daniell took an active share in addition to his university activities. He was the representative of the University of Sheffield for more than twenty years on the Joint Matriculation Board, and took a significant part in shaping its policy.

His death means a great loss to the mathematical world, but he is especially missed in the University of Sheffield, where his experience and wisdom would have been of great value in guiding the developments now in progress.

NEWS and VIEWS

Library of Sir James Hall, Bart., of Dunglass, Haddingtonshire

IN the last week of February, Messrs. Hodgson and Co., of Chancery Lane, London, offered for sale the library accumulated at Dunglass House, in East Lothian, in the latter half of the eighteenth and the earlier part of the nineteenth century by Sir James Hall (1761–1832), the distinguished geologist, and other members of his family. The collection contained many early and important works in various branches of science and in medicine, but was of more particular interest on account of the geological works included. Hall was a pioneer in experimental geology, and carried out a number of classic laboratory experiments devised to support some of the conclusions reached by his friend James Hutton, from general reasoning based on geological field work, and embodied by the latter in his "Theory of the Earth". One series of experiments was designed to show that molten basalt lava, when cooled slowly, forms a stony or crystalline mass comparable with the basalt occurring in Nature, rather than a vitreous mass, as was usually contended at that time. The second and more famous series was instituted to determine the combined effects of heat and pressure on carbonate of lime, the problem being to find out if powdered chalk could be converted into firm limestone or into marble by heating in a confined space. Hutton's view that marble would result was based on geological grounds, but was apparently at variance with experimental facts, as then known. Some preliminary trials were carried out during Hutton's lifetime, but a more prolonged and systematic series of experiments was not commenced until after the latter's death, having been postponed in deference to his marked disapproval of those who "judge of the great operations of the mineral kingdom by kindling a fire and looking into the bottom of a crucible".

The main experiments, which proved entirely successful in their object, were carried out during the period 1798–1805; and full details were recorded by Hall, in the form of a diary, in two folio volumes. These are the volumes which appeared in the sale room as Lot 98, bearing the title "Chemical Experiments made with a view to Obviate some of the Difficulties in Dr. Hutton's 'Theory of the Earth' ". It is a matter for satisfaction to be able to record that these diaries were purchased by Messrs. Quaritch on behalf of the National Library of Scotland, where they will now find a permanent and appropriate resting place. Among other works of interest sold, the writings of James Hutton were well represented, not only by his lesser-known books, but by two copies of his famous "Theory of the Earth". The publication of this book, in 1795, has long been recognized as a landmark in the history of geology. The prices obtained, £110 for one copy and £95 for the second, reflect not only its scientific importance but also its great rarity.

Dr. T. W. King (1809–47)

Thomas Wilkinson King, who died of pulmonary tuberculosis on March 26, 1847, may without undue straining of the phrase be hailed as the 'father of endocrinology'. Such an appellation is justified by his paper "On the Structure and Function of the Thyroid Gland" (*Guy's Hospital Reports*, 1, 429; 1836), in which he described the colloid secretion of the thyroid and which is remarkable for this prophetic sentence: "We may one day be able to show that a particular material is slowly formed and partially kept in reserve, and that this principle is also supplementary, when poured into the descending cava, to important functions in the course of the circulation". This original article remained almost completely forgotten until it was rescued from obscurity by Sir Humphry Rolleston (Fitzpatrick Lectures, 1933). The son of a medical practitioner at Dover, at the age of sixteen King entered Guy's Hospital, on October 4, 1824. In 1837 he succeeded Thomas Hodgkin as curator of the museum and lecturer on morbid anatomy, assuming the additional lectureship on comparative anatomy and physiology three years later. As a lecturer he was not popular, for he was a poor speaker and inclined to be over the head of the average student. A tireless worker, he founded his many novel theories on clinical observations which he verified experimentally. On December 11, 1843, King became one of the original fellows of the Royal College of Surgeons of England. He was then practising at 36 Bedford Square, London; it is recorded that "Though young, he had an aged, worn look", and a perpetual cough.

World Federation of Scientific Workers

Mr. J. G. Crowther has been appointed secretary-general designate of the World Federation of Scientific Workers. Mr. Crowther was during the War in charge of the Science Department of the British Council and is the author of several books on the history and social relations of science. The World Federation of Scientific Workers was founded last year at a conference convened by the Association of Scientific Workers in Great Britain and attended by representatives of many foreign associations of scientific workers. It is intended to serve as a centre through which the various national associations may render each other mutual advice and encouragement, to help the growth of the individual associations in their own countries, and to assist them to work out common aims and methods of organisation. It is preparing a charter of the rights and duties of scientific workers. The constituent associations work towards an agreed policy on matters of fundamental importance such as secrecy, and freedom and co-ordination in scientific research. The president of the Federation is Prof. F. Joliot-Curie, High Commissioner for Atomic Energy in France. Communications can be sent to the London office, at 15 Half Moon Street, London, W.1, or to M. P. Bonet-Maury, Institut du Radium, 11 rue Pierre Curie, Paris, V^e.

Chemicals from Petroleum

At a meeting held at the Mayfair Hotel, W.1, on March 11, an announcement was made by the Shell Petroleum Co., Ltd., of a new and extended programme for the production in Great Britain of chemicals from petroleum. In the past the main sources from which organic chemicals have been derived are coal by-products and fermentation processes. The petroleum to be used as the new raw material will be imported from sterling areas, and the productive capacity of the Shell organisation in the United Kingdom is to be expanded to give a greatly increased output. This venture has been facilitated by the exemption from import and excise duty of hydrocarbon oils used as raw material for processes of chemical synthesis. By the use of modern methods and equipment it is claimed that a high output per man will be achieved. Among the basic chemicals to be produced are acetone, methyl ethyl ketone, methyl *iso*butyl ketone, *iso*propyl alcohol, diacetone alcohol, *sec.*-butyl alcohol, *tert.*-butyl alcohol, mesityl oxide, methyl *iso*butyl carbinol and *iso*propyl ether. A big expansion in the production of sodium higher alkyl sulphates, used as detergents and wetting agents, is envisaged, the method of manufacture being based on the vapour phase cracking of a petroleum wax to produce higher olefines. Further developments include the manufacture of insecticides, fungicides and other products used in agriculture; and an experimental farm has been acquired at Woodstock, Kent, where a study can be made of the application of new products to a variety of agricultural and horticultural purposes. Owing to the absence of natural gas resources in Great Britain, the production of chemicals from petroleum in this country calls for different manufacturing methods for the basic olefines from those generally followed in the United States of America.

The Fertiliser Society

It has long been felt by the various sections of the fertiliser industry that, as in other progressive industries, there was a need for a technical society to serve the personnel of the industry and to deal with technical problems. On the initiative of the Fertiliser Manufacturers' Association, therefore, representatives of the Basic Slag Producers' Association, the British Sulphate of Ammonia Federation, the Federation of Bone Users and Allied Trades Ltd., and the Horticultural Fertilisers Association Ltd., met recently to discuss proposals. The formation is now announced of the Fertiliser Society, having as its objects: (1) the provision of a medium for discussion of scientific and technical aspects of the production, use and application of fertilisers; (2) the promotion of the interchange of views and the dissemination of information to members concerning such scientific and technical aspects. Membership is open to persons engaged in, or associated with, the manufacture of fertilisers, and such other persons as the Council from time to time approve. The secretary is Dr. G. F. New, and the offices of the Society are at 44 Russell Square, London, W.C.1.

Health and the Suppression of Dust in Mines

The relation of dust to the health of mine-workers will be the subject of meetings to be held at the Royal Institution during April 15–17. On April 15, at 5.0 p.m., the first Sir Julius Wernher Memorial Lecture of the Institution of Mining and Metallurgy will be delivered by Major-General A. J. Orenstein, chief medical officer of Central Mining—Rand Mines, Ltd., who will speak on "The History and Prevention of Silicosis with special reference to the Witwatersrand". The lecture will be open to the public, without ticket. During April 16–17, a Conference on Silicosis, Pneumokoniosis and Dust Suppression in Mines, arranged by the Institution of Mining Engineers and the

Institution of Mining and Metallurgy, will take place. There will be four sessions, the first two dealing with medical aspects, and the third and fourth with dust sampling and control. There is no fee for attending the Conference; a volume of proceedings will be published as soon as possible after the meeting. Particulars can be obtained from either of the organising Institutions, Salisbury House, Finsbury Circus, London, E.C.2.

German Scientific Periodicals

We have received a list of ninety German scientific periodicals for which permission to begin publishing has been obtained from the Control Commission. About a quarter of these have already been started. Among them are a number of journals which existed before the War, such as *Die Naturwissenschaften*, published with Prof. A. Eucken of Göttingen as editor, *Metallforschung* under Prof. Masing's direction, and also a considerable number of medical journals. Messrs. Springer intend to restart *Zeitschrift für Physik*; but this apparently has not yet begun. A new journal containing interesting articles by a number of well-known physicists is *Zeitschrift für Naturforschung*, published by Dieterich'sche Verlagsbuchhandlung, Wiesbaden (see *Nature*, Sept. 14, p. 372).

Association of British Zoologists

At the annual meeting of the Association of British Zoologists held in the rooms of the Zoological Society on January 11, the following were elected officers and new members of the council for the year 1947–48: *President*, Dr. Edward Hindle; *Hon. Secretary*, Dr. D. L. Gunn, Anti-Locust Research Centre, British Museum (Natural History), Cromwell Road, London, S.W.7; *Hon. Treasurer*, Dr. A. G. Hamilton, Royal Veterinary College, Royal College Street, London, N.W.1; *New Members of Council*, Prof. H. Gordon Jackson (re-elected under provisions of the constitution), Prof. C. M. Yonge, Dr. J. W. Evans, Dr. A. Graham and Mr. G. P. Wells. A discussion on "Careers in Zoology—Possibilities and Training" took place, an account of which is reported on page 378 of this issue of *Nature*.

Royal Society of Edinburgh: New Fellows

The following have been elected fellows of the Royal Society of Edinburgh: Mr. F. W. Anderson, senior geologist, H.M. Geological Survey, palæontologist in Scotland, Edinburgh; Dr. J. G. C. Anderson, senior geologist, H.M. Geological Survey, Edinburgh; Dr. R. N. Arnold, regius professor of engineering, University of Edinburgh; Mr. Hamilton Bailey, Denham, Totteridge, London, N.20; Dr. G. H. Bell, senior lecturer in physiology, University of Glasgow; Dr. W. P. Blount, poultry adviser to Unilever Group, Stoke Mandeville, Bucks; Dr. N. L. Bor, Forest Research Institute, Dehra Dun; Dr. L. M. Brown, lecturer in technical mathematics, University of Edinburgh; Dr. W. F. Cassie, professor of civil engineering, King's College, University of Durham; Dr. S. C. Curran, lecturer in natural philosophy, University of Glasgow; Dr. J. H. Fraser, member of scientific staff, Marine Laboratory, Aberdeen; Prof. Tom Grahame, Anatomy Department, Royal (Dick) Veterinary College, Edinburgh; Dr. G. Heslop Harrison, University of Durham; Dr. J. A. Hewitt, senior lecturer in physiology, King's College, University of London; Dr. J. M. Hyslop, lecturer in mathematics, University of Glasgow; Dr. J. M. Jackson, lecturer in mathematics, University College, Dundee; Dr. Otto Löwenstein, lecturer in zoology, University of Glasgow; Dr. A. J. Macintyre, lecturer in mathematics, University of Aberdeen; Group Captain G. S. Marshall; Dr. James Reekie, lecturer in physics and Carnegie Teaching Fellow, University of St. Andrews; Mr. J. M. Muirhead, manager, Scottish Provident Institution, Edinburgh; Mr. W. H. Senior, assistant secretary, Department of Agriculture for Scotland, Edinburgh; Dr. A. K. M. Trivedi, professor of chemistry, Lingraj College, Belgaum, India; Dr. G. R. Tudhope, lecturer in pathology, University of St. Andrews, and pathologist, Royal Infirmary, Dundee; Dr. B. Woolf, lecturer in vital statistics, Department of Public Health, University of Edinburgh.

Announcements

The Council of the Royal Society of Edinburgh has awarded the Makdougall–Brisbane prize for the period 1944–46 to Dr. William Black, of the Scottish Society for Research in Plant Breeding, for his work dealing with genetical investigations on the potato, with their practical applications.

The Textile Institute has awarded a scholarship, offered under the terms of a grant from the Cotton Trade War Memorial Fund (total value £750, tenure three years), to George H. Ewins, a cotton-spinning student at Bolton Municipal Technical College, who will now proceed to a university degree course.

Dr. William A. Hamor, an assistant director of the Mellon Institute of Industrial Research, Pittsburgh, has been given the honorary degree of doctor of laws of the University of Miami.

The Bristol, Clifton and West of England Zoological Society has agreed to provide funds for a research scholarship in vertebrate zoology tenable at the University of Bristol at the rate of £300 for three years. Many university scholarships and fellowships in the fields of physics, chemistry and related subjects are now being financed through industrial sources, and the establishment of this scholarship in the biological field is a most welcome one.

A Polarographic Discussion Panel, having as its objects the holding and the sponsoring of informal discussions on the subject of polarography as applied to chemical analysis, has been formed by the Physical Methods Group of the Society of Public Analysts and Other Analytical Chemists. Plans are in hand to arrange a first meeting in London during April. Particulars may be obtained from the honorary secretary, Mr. J. T. Stock, Chemistry Department, L.C.C. Norwood Technical Institute, Knight's Hill, London, S.E.27.

Major John A. Hunt asks us to state that inquiries in connexion with the report on the Survey of British Somaliland (see *Nature*, **158**, 511; 1946) should be addressed to the Secretary to the Government, Hargeisa, British Somaliland, via Aden; and not Burao as indicated in the bibliographic reference.

Erratum.—In the communication entitled "Constitution of Strychnine and its Relation to Cinchonine" by Sir Robert Robinson in *Nature* of February 22, p. 263, the bond from the quinoline nucleus should be attached to the 4-position and not to the 3-position as printed.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Use of a Cyclotron to Detect Short-Period Activities

THE cyclotron at Cambridge has a high-frequency set which can be readily modulated, allowing information to be obtained on activities of period varying roughly from 100 microseconds to 1 second.

The apparatus (Fig. 1) consists of a master oscillator driving a ring-of-twelve scaling unit. Position 1 on this ring of twelve, operating through the modulator, turns on the radio-frequency voltage to the dees and delivers a burst of particles. Position 2 is a blank, and positions 3–12 connect the counter impulses, via a gating unit operated by the ring, to ten separate scales-of-four with separate mechanical recorders.

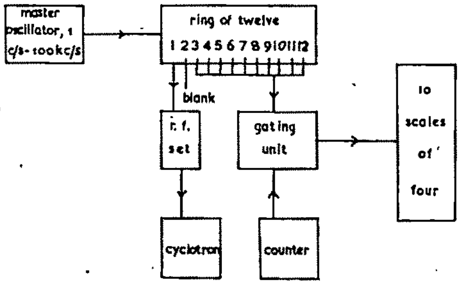


Fig. 1

To test this arrangement on a known reaction, the modulator time constants were adjusted to allow the master oscillator to run at 5 cycles per second, and the cyclotron output (for this experiment 5 MeV. protons, 70 microamp. beam current) was used to produce neutrons from a lithium target. Close to the target was placed a Geiger counter with a thin mica window outside which was a sheet of beryllium metal. The assembly was screened on all sides by about 1 in. thickness of lead. The Be($n\alpha$) reaction giving He^6 would be expected, and a period of about 0·8 sec. was found.

It was decided to check the period, and a sequence of forty-four short runs was made, each of 30 sec. duration. Between runs the apparatus was switched off to allow the background to decay to a predetermined figure—the time taken being 5–9 minutes. This background was found to be roughly proportional to the integrated number of neutrons in the 30 sec. run, and is probably due to neutron-induced activities in the brass wall of the counter, the period of 5 min. agreeing with one of the copper isotopes.

The results were:

Channel No.	3	4	5	6	7	8	9	10	11	12
Totals (each unit equals 4 β-particles)	433	368	347	286	265	233	215	198	177	157
Background of 57 subtracted	376	311	290	229	208	176	158	141	120	100

These (Fig. 2) show an exponential decay with channel number, giving a half-life of 4·74 channels, or 0·87 sec.

The errors in this determination are partly statistical (± 0·04), and partly arise from the determination of the background count. This was estimated by doing background measurements before and after particular runs, and also from another set of data using the proportionality mentioned above. The error is probably ± 10, which would change the period by about ± 0·04 sec. The final result is, therefore, 0·87 sec. ± 0·06, agreeing with other determinations.

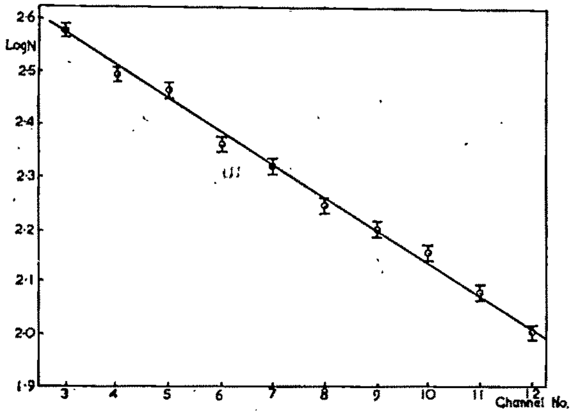

Fig. 2

One other observation of interest was made. The master oscillator was varied over the range 5 c./sec. to 6,000 c./sec. Apart from the He^6 period, the only effect observed was an increased counting-rate on the first two or three channels at the highest speed. This may well have been due to slow neutrons scattered from the screening tanks around the cyclotron. There were certainly no other periods from 10^{-3} sec. to 1 sec. of comparable cross-section to the Be($n\alpha$)He^6.

We should like to thank Mr. Kandiah's group for building the electronic apparatus for us.

Presence of a Penetrating Component in Extensive Showers in the Atmosphere

THE existence of a penetrating component in extensive atmospheric showers has been investigated by several workers[1], using different methods. Results obtained with cloud-chambers[2] do not seem to justify a final conclusion. Cocconi and co-workers[3], using counters, decided in favour of the presence of meson showers simultaneous with extensive showers; more recently, Rogozinski[4], using counters driving neon lamps, concludes that mesons are probably associated with extensive showers.

We have undertaken an investigation using counters, so conducted that a greater number of criteria is available for distinguishing penetrating particles from the electrons and photons existing in the showers. This distinction was based upon the following properties of penetrating particles: (1) high penetrating power; (2) low multiplication probability while crossing thick iron or lead layers; (3) penetrating particles dissipate energy in a different way from high-energy photons and electrons, so that absorption varies differently as the atomic number of the absorbers is varied.

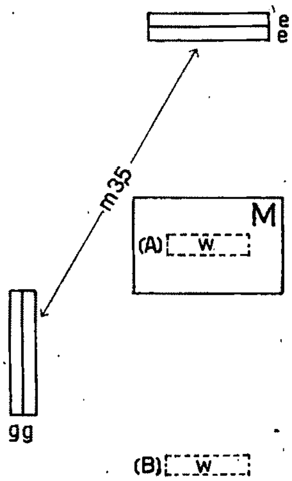

Fig. 1. EXPERIMENTAL OUTLAY (NOT TO SCALE)

Our experiments were carried out at a height of 2,100 m. above sea-level (at Lago d'Inferno, lat. 46° 01′ N., long. 9° 32′ E.) during the summer of 1946. The experimental arrangement is shown in Fig. 1. The counters to which the same identification letters are assigned are in parallel. Counters *e*, *f*, *g* in coincidence detect the presence of extensive showers. In Fig. 2, group *M* (selector) includes seven counters, of which twofold coincidences $a + b$ and fourfold coincidences $a + b + c + d$ were registered. Twofold coincidences which were not accompanied by fourfold coincidences were accounted for as being due to non-multiplying particles (such as mesons) crossing layers S_1 and S_2; fourfold coincidences as being due to high-energy photons and electrons, or to simultaneous arrival of several penetrating particles. The selector was arranged in accordance with Arley's[5] and Molière's[6] theoretical calculations on the multiplication and lateral spread of shower electrons.

Since we are interested in events coinciding with the extensive showers as detected by $e + f + g$, we measured the $a + b + e + f + g$ coincidences (referred to as V; the number of random coincidences, directly evaluated, was found to be less than 5 per cent of the effective ones), the $a + b + c + d + e + f + g$ coincidences (VII), and eventually we appraised the difference between them, V–VII. The table gives observed counting-rates per minute for different layers S_1 and S_2:

S_1 (cm.) 1	S_2 (cm.) 2	V/min. 3	VII/min. 4	$\frac{\text{V} - \text{VII}}{\text{min.}}$ 5	$\frac{\text{V} - \text{VII}}{\text{VII}}$ 6
5 Pb	1·6 Pb	$4{\cdot}0 \pm 0{\cdot}4 \times 10^{-2}$	$3{\cdot}3 \pm 0{\cdot}4 \times 10^{-2}$	$7{\cdot}7 \pm 1{\cdot}6 \times 10^{-3}$	0·2
5 ,,	5 ,,	$2{\cdot}7 \pm 0{\cdot}2 \times 10^{-2}$	$2{\cdot}2 \pm 0{\cdot}15 \times 10^{-2}$	$5{\cdot}2 \pm 0{\cdot}8 \times 10^{-3}$	0·2
10 ,,	5 ,,	$7{\cdot}9 \pm 0{\cdot}9 \times 10^{-3}$	$5{\cdot}3 \pm 0{\cdot}7 \times 10^{-3}$	$2{\cdot}6 \pm 0{\cdot}5 \times 10^{-3}$	0·5
15 ,,	5 ,,	$4{\cdot}3 \pm 0{\cdot}6 \times 10^{-3}$	$2{\cdot}5 \pm 0{\cdot}4 \times 10^{-3}$	$1{\cdot}8 \pm 0{\cdot}4 \times 10^{-3}$	0·7
18 Fe	5 ,,	$1{\cdot}2 \pm 0{\cdot}14 \times 10^{-2}$	$8{\cdot}8 \pm 1{\cdot}3 \times 10^{-3}$	$3{\cdot}4 \pm 0{\cdot}8 \times 10^{-3}$	—
36 ,,	5 ,,	$5{\cdot}9 \pm 0{\cdot}8 \times 10^{-3}$	$4{\cdot}5 \pm 0{\cdot}7 \times 10^{-3}$	$1{\cdot}4 \pm 0{\cdot}4 \times 10^{-3}$	—

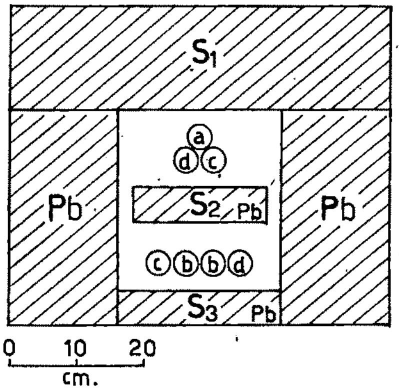

Fig. 2. VERTICAL CROSS-SECTION OF THE SELECTOR *M*

Consider the data obtained for lead (first four lines of the table). From columns 4 and 5, it appears that, as the thickness of the lead layer is increased, the frequency of VII coincidences decreases more quickly than the frequency of the V–VII coincidences. In column 6 the rate change of the ratio $\frac{\text{V–VII}}{\text{VII}}$ is separately shown for the sake of clearness. It is to be noted that, were coincidences V–VII due to shower electrons which originated twofold rather than fourfold coincidence in the selector system, the ratio $\frac{\text{V–VII}}{\text{VII}}$ should decrease or at most remain unchanged; in fact, the selector's efficiency increases as we increase the thickness of layers S_1 and S_2 [5,6].

The existence of V–VII events and their frequency-rate constitute, therefore, preliminary proof of the presence of penetrating particles in extensive showers. Further proof is given by our results with iron. The frequency-rates of coincidences V and, especially, of coincidences V–VII, for 18 cm. iron plus 5 cm. lead and 36 cm. iron + 5 cm. lead, are less than those found for 5 + 5 cm. and 10 + 5 cm. lead respectively, whereas these thicknesses of lead should be equivalent to the above-mentioned thicknesses of iron, were the coincidences only due to high-energy electrons or photons.

The absorption curve which may be deduced from column 5 shows that, whenever the penetrating component of extensive showers is due to mesons, these would have a spectrum of lower energies than those of mesons present in total radiation.

It should, however, be noted that some of the events due to penetrating particles may have accumulated in coincidences VII by the effect of secondary knock-on electrons, or owing to the simultaneous presence of several mesons.

During the measurements, about two hundred photographs were also taken in a cloud-chamber, in coincidence with the extensive showers detected by the counters. The chamber was operated in the two different positions *A* and *B* (see Fig. 1). In position *A* (chamber under the selector, $S_1 = S_2 = 5$ cm. lead, S_3 removed) no photographs were obtained which showed for certain more simultaneous mesons (meson showers); in the *B* position, photographs appear distinctly richer in tracks when the cloud-chamber is driven by VII coincidences than when it is driven by V–VII coincidences.

A detailed report of these measurements will be published elsewhere.

Spread of Discharge in Geiger Counters

The important differences in the behaviour of slow and fast counters noticed by Trost[1] and others[2,3] have led several workers to investigate, in a preliminary manner, the factors which prevent the discharge, developed near the path of the incident primary particle, from spreading along a counter, or from one counter to another enclosed within the same envelope. The experiments of Stever[4], Wilkening and Kanne[5], Ramsey[6] and Curran and Strothers[7], and others are well known. Hill and Dunworth[8] have recently reported results on the velocity of discharge spread.

It appears to be implied in some of the earlier discharge-localization experiments[9] that, provided the interruption in the path of the discharge, whether it be a bead on the wire or a gap between two cathodes, etc., is of reasonable size, the discharge will very rarely, or never, spread in a fast (self-quenching) gas. Wilkening and Kanne[5] showed qualitatively that the discharge-spread in fast counters increased with decreasing concentration of quenching gas, etc.

We have recently re-investigated this matter with divided cathode counters similar to those used by Ramsey[6] and others, about 12 in. in length and containing six 2-in. or twelve 1-in. copper cathodes (Fig. 1). The cathodes were cleaned in acid and may be described, therefore, as unoxidized in the gross chemical sense. One of the extreme cathodes was irradiated with radium γ-rays using a carefully tested collimator system, and double coincidences between this cylinder and those farther down the tube, taken in turn, were measured. The intervening cylinders were operated at voltages just below their counting thresholds. Subsidiary experiments were made to assess the importance of random coincidences, the effect of which was shown to be negligible, and the usual counter tests were applied to the individual cylinders to check their behaviour. The plateaux even for the 1-in. long, ¾-in. diameter cathodes were satisfactory; they were ∼ 160 volts long with alcohol/argon, but were less with methane fillings. The main results were not thereby affected.

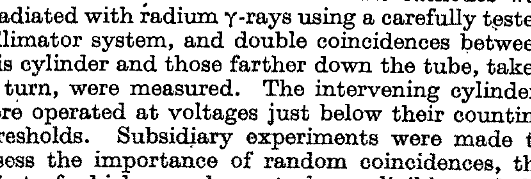

Fig. 1

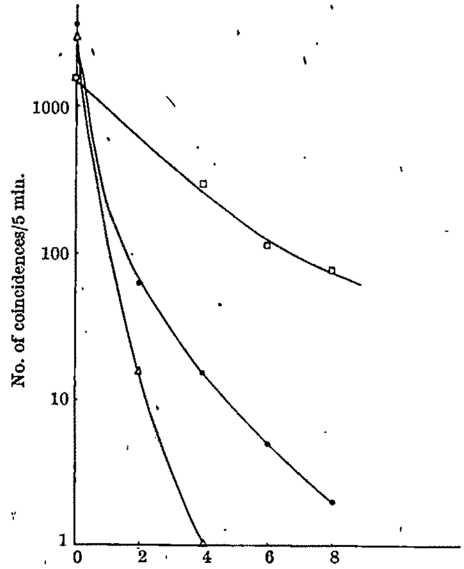

Fig. 2. △, 1·0 cm. Hg ethyl ether, 10 cm. Hg argon
□, 2·5 cm. „ methane, 7·5 cm. „ „
●, 0·4 cm. „ ethyl alcohol, 10 cm. „ „

Fig. 2 gives some typical results for fast counter fillings. Experiments with argon alone showed much greater discharge spread, namely, approximately 100 per cent even for 8-in. counter length; in this case it was necessary to use external quenching in order to obtain a satisfactory resolving time in the coincidence circuit. It is seen from Fig. 2 that localization is by no means complete, and even with 2 in. between the irradiated counter and its coincidence partner, roughly 1 per cent of the primary discharges caused spreading of the discharge. Similar results taken with a different experimental arrangement were obtained by Curran and Strothers[7].

It is scarcely possible to interpret these results without further work (now in progress); a particular point of interest is to decide whether the discharge spreads by virtue of (*a*) photo-ionization in the gas, or (*b*) through emission of photo-electrons at the cathodes; it is unlikely that the spread of discharge is caused by diffusion of electrons since the field in the intervening cathodes (Fig. 1) would remove them (see also Korff[9], p. 95). Some preliminary experiments we have made with another special counter lead to the tentative conclusion that the mechanism (*b*) above is the more important cause of discharge spread. The discharge invariably spread from the end counter to that next to it (⅛-in. gap) when they were used in coincidence, due presumably to field penetration. Coincidence counting was thus started with the first and third cylinders.

The results are of interest in that they show the presence of marked photon effects in fast counters. Similar results have been published previously[5], using a different and more qualitative method of presentation, but the absence (relative or total) of such effects, particularly those caused by relatively long wavelength photons, appears sometimes to be postulated without reason. The present results imply that photo-electrons are emitted more or less continuously from the cathode, or gas in the counter near it, during the early part of pulse formation in a fast counter, that is, so long as photons are being produced. The basic conclusion, due to Korff, that in fast counters the positive-ion sheath causes no secondary emission on arrival at the cathode, is, of course, unaffected by the above results.

Stability Constants of Internal Complexes

Apart from the results of a series of studies dealing with complexes of copper, little is known of the stability of internal complexes. Calvin and his collaborators[1] have found wide variation in the stability of complexes of copper formed from a series of β diketones and *o*-hydroxy-aromatic aldehydes. It is a matter of interest to determine whether a similar wide variation of stability occurs with complexes formed by the co-ordination of a series of metals with one chelating molecule. For this reason and also because stability constants may eventually help to throw some light on the inactivation of essential trace metals in biological systems[2], we have begun an investigation of complexes formed by a variety of metals.

Working in the first instance with 50 per cent water – 50 per cent dioxane solutions and using substantially the method employed by Calvin and Wilson[1], we have obtained the following values (see Table 1) for the stability constants of complexes formed by a series of bivalent metal ions with salicylaldehyde. The reactions involved are

$$Me^{++} + K\bar{e} \rightarrow MeKe^{+}$$
$$MeKe^{+} + K\bar{e} \rightarrow MeKe_2,$$

where $K\bar{e}$ represents the bidentate chelate minus a hydrogen ion. K_1 and K_2, the equilibrium constants for the two successive steps, are related to K_{av} as follows:

$$(K_{av})^2 = K_1.K_2 = \frac{[MeKe_2]}{[Me^{++}][K\bar{e}]^2}.$$

Table 1

Metal	Radius of metal*	Log K_1	Log K_2	Log K_{av}
Pd	1·32 A.	7·74	7·03	7·39
Cu	1·32	7·40	5·91	6·65
Ni	1·39	5·22	3·97	4·59
Pb	1·46	5·06	4·04	4·55
Co	1·32	4·67	3·63	4·15
Zn	1·31	4·50	3·60	4·05
Cd	1·48	4·62	3·14	3·88
Mg	1·40	3·69	3·11	3·40

* The values quoted in this column are tetrahedral or square covalent radii taken from "The Nature of the Chemical Bond" by L. Pauling (Cornell Univ. Press, 1939).

Preliminary work with other chelating substances such as glycine and oxine shows that the stability constants of the metal complexes fall in much the same order as with salicylaldehyde, except that occasionally the position of neighbouring metals is reversed. Not enough types of chelate molecules have yet been studied to say whether this similarity of order is general. Attempts to obtain values of K_{av} for salicylaldehyde complexes in water by a process of extrapolation, using values obtained with water–dioxane mixtures containing progressively less than 50 per cent dioxane, were not satisfactory owing to the fact that even in mixtures containing as little as 10 per cent dioxane the solubility was too low. However, by using acetylacetone as the chelating substance, it was found practicable to work with water solutions and thus to observe the effect of change of solvent on the magnitude of K_1, K_2 and K_{av}. The following values were obtained for nickel acetylacetone in different solvents.

Table 2

Solvent	K_1	K_2	K_{av}
50% dioxane	6·82	5·24	6·03
20% "	6·12	4·79	5·46
Water	5·92	4·57	5·25

It is not yet clear what factor or factors determine the order of the metals in Table 1. Electronegativity of the metal might be expected to play some part. If this were so and if electronegativity is accurately defined by the relation recently deduced by Gordy[3], we should expect to find a correlation between the covalent radii of bivalent metals and the stability of the complexes formed by them. From Table 1 it can be seen that there is no simple relation between these two constants.

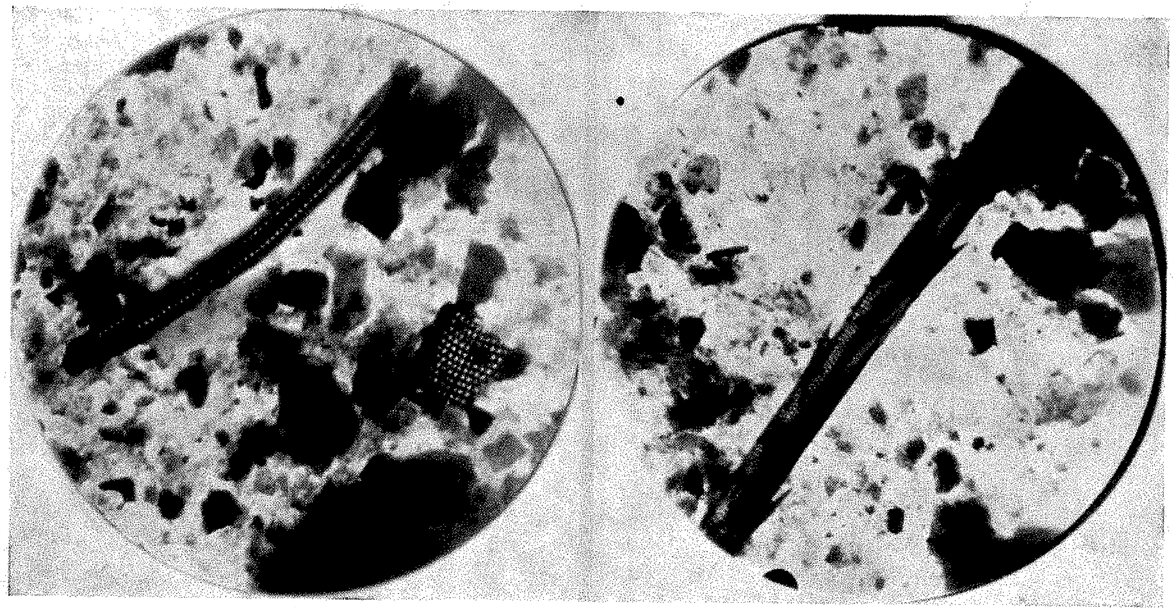
Preparation of Thin Specimen Films

A film of cellulose nitrate or a similar material is laid on a water surface and transferred to a specimen holder. A very thin layer of beryllium or aluminium is then deposited on the film from the vapour phase, after which the cellulose nitrate is dissolved away. Only the metal film then remains, and its lack of visible structure can be checked by photographing in the electron microscope. The durability and resistance of the layer to chemical attack are very high. A matter of great importance in the study of specimens in which completely opaque particles occur on the film is that the metal film readily conducts away absorbed energy. With such particles, however, films of cellulose acetate or similar materials are very easily broken. Beryllium and aluminium films of as little as 20 A. thickness (diameter 100 μ), and also aluminium films 12 A. in thickness, have been prepared by this procedure.

Because of the absorption being slight in this film, it is possible to make a closer study of minute



A *B*

Fig. 1

B. A beautifully branched minute fine structure. × 28,000

structures, such as large molecules, and their shape.

With the aid of such resistant metal films, it is possible, by taking series of photographs, to follow the reactions of one and the same particle of a substance when subjected to different chemical treatments. It is not difficult to number the holes on the preparation holder in such a way that any given hole can be easily located.

Observation of Diatoms. The method described elsewhere (see p. 354 of this issue of *Nature*) for the investigation of the structure of clay can also be employed with advantage for the study of diatoms. Several photographs of diatoms have been taken in connexion with studies on post-glacial clays. It is found that diatoms lying in the clay surface accompany the cellulose acetate film when it is drawn away. Since the cellulose nitrate encloses the diatoms within an envelope of sufficient strength, they can readily be removed from the clay. Even diatoms of extremely fine structure or of great fragility can be loosened and transferred to an aluminium or beryllium film for observation in the electron microscope. In cases where the diatoms consist of adjacent fragments, they also can be studied in the microscope with their original relative positions in the clay undisturbed, which has hitherto been impossible.

The high resolving power of the electron microscope employed makes it possible to study diatoms of submicroscopic size. Diatoms have thus been seen which have hitherto been unobservable on account of their minute dimensions. Of interest is the detailed study of the structure of the diatoms, especially the structure of the shells, which is sometimes so fine that magnifications of more than 100,000 are necessary to disclose it.

Ion Exchange Resins as Catalysts

Ion exchange resins, in the hydrogen form, appear to offer several advantages as acid catalysts, such as the possibility of their continuous or repeated use without renewal, and their easy removal, by decantation or otherwise, from the reaction mixture. A paper on the subject has now been published by Sussman[1], who reports several examples of the successful use of 'Zeo-Karb' in esterification, alcohol dehydration and other acid-catalysed processes. Sussman was less successful with ester hydrolysis, and attributes this to the poor contact attainable in the three-phase system ester–water–catalyst.

We have examined the hydrolysis of some esters, using 'Amberlite IR-100' as catalyst; this is a synthetic resin containing one equivalent of strong (sulphonic) acid groups in approximately 500 gm. of resin. 1–4 gm. of resin were used per 100 ml. of liquid, the mixture being agitated in a thermostat at 25° C. Methyl and ethyl acetates, both in aqueous solution, underwent hydrolysis according to first-order reaction equations, whereas with *n*-butyl and benzyl acetates the reaction was of zero order so long as ester was present as a separate phase. If we assume in these latter cases that the reaction occurs in the saturated aqueous phase, we may compare our rates with those previously reported[2] for the same reactions catalysed by hydrochloric acid. Regarding the 'Amberlite' as a strong acid of equivalent weight 500, we find that the heterogeneous catalyst is the more efficient of the two, by factors of 1·7 for methyl acetate, 2·3 for ethyl acetate and 9·8 for butyl acetate.

We think that these results illustrate the importance of adsorption in resin-catalysed reactions; in general, reaction-rates will be governed not only by solubilities but also by the relative adsorptions of reactant, product and solvent molecules at the resin surface.

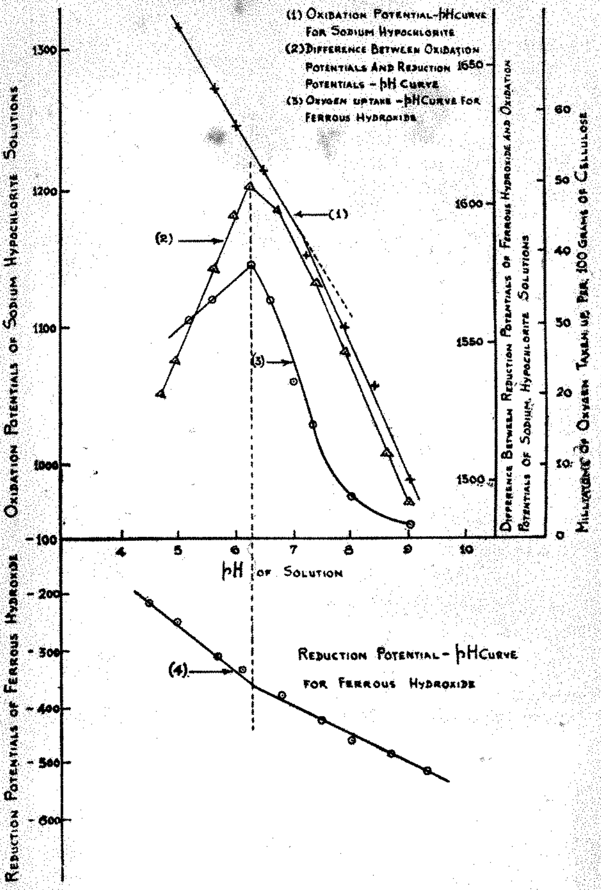
Reduction Potentials of Ferrous Hydroxide

The accelerated oxidation of cellulose in the presence of ferrous hydroxide by dilute solutions of sodium hypochlorite, buffered to different hydrogen ion concentrations, has been studied by Nabar and Turner[1]. It was shown that the maximum absorption of oxygen and the maximum attack on cellulose occurred at about *p*H 6·4. From similar earlier investigations, with leuco vat dyes as accelerators, Nabar, Scholefield and Turner[2,3] had shown that the maximum oxygen uptake and the maximum oxidation of cellulose occurred at about *p*H 7·4. The obvious dependence of the oxidizing intensity of sodium hypochlorite solutions on the specific substance present on cellulose may be attributed to the differences in their physico-chemical properties, such as reduction potentials, ease of oxidation, etc. The present work was undertaken to study the reduction potential of ferrous hydroxide and examine its influence on the oxidation mechanism.



A few attempts[4,5] have been made to measure the reduction potentials of ferrous hydroxide; but values proposed by different investigators show considerable variation. The problem under investigation was to determine the reduction potentials of ferrous hydroxide in dispersed condition on cellulose, since the activation of oxidation has been found to occur when cellulose is impregnated with the ferrous hydroxide. The following procedure was finally evolved and adopted for the measurement of the potentials.

Ferrous hydroxide was precipitated on loose cotton tightly wrapped around a platinum wire sealed in a glass tube. The impregnated cotton was washed in air-free distilled water, and the electrode was immediately immersed in a specially designed flask containing an air-free buffer solution of known hydrogen ion concentration through which hydrogen was being rigorously bubbled. With saturated calomel half-cell as the reference electrode, the E.M.F. of the following cell was measured at regular intervals:

$$\underset{+}{\mathrm{Hg}} \mid \mathrm{Hg_2Cl_2}, \text{ Sat. KCl.} \parallel \text{Sat. KCl} \parallel \begin{array}{l}\text{Ferrous hy-}\\ \text{droxide on}\\ \text{cotton in}\\ \text{buffer solu-}\\ \text{tion.}\end{array} \mid \underset{-}{\mathrm{Pt}}$$

The E.M.F. reached a constant value after about fifteen minutes and remained steady for two to four hours. This value was taken as the E.M.F. of the cell referred to above. The oxidation potential of sodium hypochlorite was measured as described by Nabar, Scholefield and Turner[3]. Measurements of oxygen uptake by cotton impregnated with ferrous hydroxide were carried out simultaneously. All measurements were made at 30° C. The results are illustrated in the accompanying graphs.

Curve 1 shows the relation between the *p*H of sodium hypochlorite solutions and the oxidation potentials. Curve 4 shows the relation between the *p*H and the reduction potentials of ferrous hydroxide on cotton. The relation of the difference between the oxidation potentials of sodium hypochlorite to the reduction potentials of ferrous hydroxide and the *p*H is shown in curve 2, and the relation between oxygen uptake by cotton impregnated with ferrous hydroxide and the *p*H of hypochlorite solution is shown in Curve 3. It is interesting to see the close resemblance in the shape of curves 2 and 3, and the coincidence of the *p*H for maximum oxygen uptake and the *p*H for the maximum difference in the potentials with the break in the *p*H-reduction potential curve. The results will be discussed in detail elsewhere.

Inhibition of Catechol Bacteriostasis by Molybdates

Large areas in and near Somerset are unsuitable for grazing because they cause severe diarrhœa in cattle. These areas, called 'teart', are found on the argillaceous Lower Lias. The disease has been shown[1] to be due to an excess of soluble molybdates in the herbage and the soil; it can be cured by adding copper salts to the diet. A possible explanation of the effect of molybdates is suggested by the following observations.

Molybdates form red complexes with catechols[2,3]. These are not very stable, and we have found that the colour disappears on warming, or on shaking with ether to remove catechol. Now it is likely (though unproved) that catechols occur in the intestine of ruminants, because they are present in many fodder plants[4] and because the tyrosine of proteins is converted by intestinal bacteria to phenol[5] which, in the presence of suitable plant[6] or animal[7] oxidases, is oxidized to catechol.

Catechol, like other phenols, is bacteriostatic, but might be less so in the presence of molybdate owing to the formation of the complex. We have found that, in fact, potassium molybdate does reduce the bacteriostatic action of catechol when added in concentrations which by themselves have no effect on the bacteria. In a serial dilution test at 25° C., a catechol concentration of *M*/1280 was needed to inhibit the growth of *Staphylococcus aureus*: when half a mole of potassium molybdate was added per mole of catechol, the concentration of catechol needed to inhibit growth was raised to *M*/160. Even *M*/20 potassium molybdate was without effect on *S. aureus*. With *Escherichia coli* similar results were found; the minimum bacteriostatic concentration of catechol was raised from *M*/160 to *M*/40 by adding half a mole of potassium molybdate per mole of catechol used.

Phenol, *o*-cresol and resorcinol form no coloured complexes with potassium molybdate; correspondingly, we found that it had no effect on their minimum bacteriostatic concentrations.

These biological results suggested that a complex, $K_2MoO_4.2C_6H_6O_2$, was formed, and a colorimetric experiment was made at 25° C. to test this theory.

Molarity in aqueous solution		Colour intensity in arbitrary units
Potassium molybdate	Catechol	
0·06	0·02	1·00
0·533	0·0266	1·29
0·04	0·04	1·84
0·0266	0·0533	2·27
0·02	0·06	1·77

The total molarity of solute is kept constant, and the colour intensity, and hence presumably the concentration of the complex, is a maximum at a proportion equivalent to $K_2MoO_4.2C_6H_6O_2$.

These facts are compatible with the theory that the activity of bacteria in the normal intestine is controlled by catechols: that molybdates reduce the effective concentration of catechols by forming complexes: and that with the removal of the control, bacterial activity becomes excessive and causes diarrhœa. It is realized that further investigation would be needed to confirm this theory; in particular, the effect of copper as an antidote still requires explanation.

I am grateful to Messrs. McGowan and Brian for allowing me to read their letter and to add my comments. Some data obtained in 1943, when working in the Unit of Animal Physiology at Cambridge, are of interest in connexion with their observations. It was found that fresh aqueous plant extracts give a colour reaction when molybdate is added. This reaction is due to the presence of substances, usually classified as 'tannins', which contain vicinal phenolic hydroxyl groups. Fresh grass cuttings were fed for two days to a rumen-fistula sheep; the rumen contents were then removed through the fistula. An extract of the ingesta thus obtained gave a colour reaction characteristic of catechols, with both ammonium molybdate and ferric chloride. This shows that the reaction between molybdate and catechols suggested by McGowan and Brian does, in fact, occur. Their explanation still remains to be tested by experiments on animals, but the readiness of molybdates to form organic complexes must be an important factor in the etiology of molybdate poisoning in cattle.

Succinic Dehydrogenase in Protozoa

THERE is, as yet, relatively little information about the occurrence of individual enzymes in Protozoa. We have been successful in demonstrating the presence of a succinic dehydrogenase in homogenates of *Paramecium caudatum*. This has been done using a modified Cartesian diver respirometer of macro dimensions (40–60 μl. total volume).

Three-day cultures were concentrated and freed from bacteria by a process of electrically directed migration followed by centrifugation. Cell-structure in the suspension ($2–6 \times 10^4$ organisms/ml.) was destroyed by grinding for two minutes between ground-glass surfaces at 0° C. The resulting homogenate was brought to *p*H 7·2 with phosphate buffer and its oxygen uptake in the presence of succinic acid, methylene blue, and inhibitors was studied. The final concentrations used were: succinate, 0·05 *M*; methylene blue, 0·5 mgm./ml.; phosphate buffer, 0·03 *M*; malonate, 0·08 *M*; cyanide and azide, 0·01 *M*; The *Q*'s (μl. oxygen/10^4 organisms/hour) are set out in Table 1.

TABLE 1

	Q
Homogenate	1·9
„ + succinate	4·3
„ + „ + KCN	1·8
„ + „ + NaN_3	2·0
„ + „ + methylene blue	6·0
„ + „ + „ „ + KCN	4·8
„ + „ + „ „ + malonate	2·0

These results show that succinate doubles the endogenous oxygen uptake, and that cyanide or azide abolishes this increase. In the presence of succinate, methylene blue produces a further increase, and is able to offset the cyanide inhibition. Malonate completely abolishes the increase of oxygen uptake which is caused by succinate.

For comparison, Table 2 shows the effect of some of these factors on the endogenous respiration.

TABLE 2

	Q
Homogenate	1·9
„ + KCN	0·8
„ + NaN_3	1·1
„ + methylene blue	1·9

From these tables it follows that cyanide inhibits the endogenous respiration by 56 per cent and the extra respiration due to succinate by 58 per cent. The corresponding figures for azide are 44 and 63 per cent. Failure of methylene blue to stimulate the endogenous respiration of the homogenate may indicate lack of substrate, or, conversely, a sufficient supply of carriers, in the original system.

While indicating that *P. caudatum* contains a succinic dehydrogenase essentially similar to that found in the Metazoa, the results have direct bearing on the question of cyanide-stability of respiration often reported in Protozoa, and should be interpreted in the light of the occurrence of cytochrome oxidase[1].

The investigation will be published in full elsewhere.

Histological Distribution of Alkaline Phosphatase in Helminth Parasites

THE organisms used in this investigation were *Ascaris lumbricoides*, from the small intestine of the pig, and *Moniezia expansa*, from the small intestine of the sheep. They were brought to the laboratory in host gut contents contained in vacuum flasks and were fixed within two hours of the time of their removal from the host. The histological distribution

Fig. 2. CUTICULAR REGION IN A TRANSVERSE SECTION OF A MATURE SEGMENT OF *Moniezia expansa* (× 400) STAINED WITH HÆMATOXYLIN-EOSIN BY THE USUAL METHODS

Fig. 3. CUTICULAR REGION IN A TRANSVERSE SECTION OF THE SCOLEX OF *Moniezia expansa* (× 400) STAINED FOR ALKALINE PHOSPHATASE. THE THICK 'CUTICLE' IS ABSENT AND THE PHOSPHATASE REACTION WAS NEGATIVE

Fig. 4. INTESTINE IN A TRANSVERSE SECTION OF *Ascaris lumbricoides* (× 400) TAKEN FROM ABOUT THE MID-POINT OF THE PARASITE. THE SECTION WAS STAINED FOR ALKALINE PHOSPHATASE, THE SMALL BLACK BODIES IN THE INTESTINAL CELLS INDICATING THE POSITIVE REACTION

of alkaline phosphatase was determined by the method of Gomori[1], using sodium glycerophosphate as a substrate.

The enzyme appeared to be present on or in the cuticle of mature segments of the cestode in considerable amounts (Fig. 1). In sections stained by the usual methods with hæmatoxylin-eosin, this cuticular region stained a dark blue colour (Fig. 2). Only a very faint brown deposit could be seen on the extreme outside edge of the cuticle after incubating sections in the absence of substrate and staining by either the cobalt nitrate or silver nitrate methods. When this 'cuticle' was absent as in young proglottids, no phosphatase reaction was obtained (Fig. 3). Apart from that in the cuticular region, the enzyme was found only in tissues surrounding developing eggs, and then only in small amounts.

Small spherical bodies in the intestinal cells of the nematode *Ascaris lumbricoides* gave a phosphatase reaction (Fig. 4). No other tissues of the parasite gave a positive reaction.

Chandler[2] has shown that certain tapeworms are dependent on host *dietary* carbohydrate for development. This would indicate that the parasites concerned obtained their carbohydrate from the intestinal contents of their host, implying that absorption took place through the parasite body surface. Glucose is absorbed from the intestinal contents of *Ascaris lumbricoides*[3]. It would appear then that the helminth parasites examined showed greatest concentrations of alkaline phosphatase in those regions which are associated with the absorption of carbohydrate. This finding is, therefore, in accordance with the hypothesis concerning the phosphorylation mechanism of absorption of glucose in the intestine and kidney[4,5].

I wish to acknowledge the assistance given by Mr. L. Turk.

Co-existence of Two Different Esterases in Liver Juice

WE have recently reported[1] the inhibition of the esterases contained, *inter alia*, in glycerol extracts of pancreatin and in liver juice by emulsifying the substrates employed (methyl butyrate, ethyl butyrate and ethyl propionate) with gum arabic. The cleavage of glycerides such as monobutyrine or olive oil, however, was not inhibited by this emulsification procedure. We therefore concluded that there are virtually two enzymatic systems present in these extracts, namely, a lipase splitting the esters of glycerols, and an esterase cleaving esters, where glycerol is replaced by lower alcohols.

Meanwhile, the observation was made that a further subdivision of the esterase system both in respect of pancreatic and liver extracts is possible, if the above-mentioned aliphatic ester compounds are being replaced by esters consisting of at least one aromatic constituent such as in ethyl benzoate. The cleavability of ethyl benzoate is not inhibited by emulsification with gum arabic, contrary to the findings with esters consisting of an aliphatic alcohol and an aliphatic acid.

The question whether there is a separate 'salolase' in liver juice or in pancreatic extracts concerned with the splitting of aromatic esters has been widely discussed without arriving hitherto at any definite conclusion[2]. Recently, I. S. Falconer and D. B. Taylor reported the isolation from liver juice of an enzyme precipitate of esterase 10–15 times purer than whole liver[3]. They arrive at the conclusion that their preparation is not identical with the purified esterase prepared by E. Baman and co-workers, on the grounds of the different solubilities of the precipitable materials, and conclude: "It therefore appears that there are two liver esterases which we will refer to in order of their solubility as liveresterases I and II until a more satisfactory basis is found for their characterisation".

Without excluding the possibility that the esterase system of liver might be composed of more than two components, it would be worth while to investigate whether there exists a correlation between our two esterases (one of which is not inhibited by gum arabic) and Falconer and Taylor's esterase I and II.

Our method of emulsification, which is an improvement on that formerly used, is as follows. 2 millimoles of each ester (stored permanently in a refrigerator at 2° C.) are mixed in a small porcelain mortar with half their weight of recrystallized commercial gum arabic, and are vigorously ground for approximately 5 sec. 0·5 ml. amounts of phosphate buffer solution (*p*H 7) are then added from a burette at intervals of 10–15 sec. (temperature of buffer solution, 15° C.). Following the addition of each portion of buffer, the mixture is again vigorously ground. After 5 ml. have thus been introduced, the mixture is quantitatively transferred to a conical incubation flask of 50 ml. capacity with a 20 ml. mark. Small portions of buffer are used to rinse the sides of the mortar before the mixture is transferred to the flask, which is filled up with buffer to 20 ml.; 2 ml. of beef liver juice (diluted with three parts of distilled water) and 5 ml. samples are taken for titration at intervals of 0, 20, 40 and 80 min. When pancreatic glycerol extracts are employed, 6 ml. of a glycerol extract (diluted with two parts of buffer solution) are added, and samples are taken at intervals of 0, 45, 105, 165 and 225 min. The inhibitory effect thus obtained ranges from 65 per cent to 100 per cent, depending upon the ester and the sample of enzyme preparation. (The strongest inhibition is obtained with methyl butyrate emulsion if cleaved by pancreatic esterase. Tests carried out with one and the same sample were fairly constant; however, the amount of inhibition suffered by different enzyme preparations was found to vary by about 20 per cent. Cleavage of the esters in the absence of gum arabic was not subject to fluctuations.)

Provided that esterase I and II are separable from each other, I suggest that they should be tested as to their behaviour towards the emulsions of aromatic and aliphatic esters; for example, methyl butyrate and ethyl benzoate.

The objection might be raised that our esterases from beef liver extracts are not necessarily identical with those obtained from pig liver. Unfortunately, it is impossible in Palestine to obtain fresh pig liver at regular intervals. Since, however, this inhibitory effect is very general and has been observed in extracts prepared from living material covering nearly the whole range of biology (pig pancreas, beef liver, different organs of the honey bee, worker maggots of the honey bee, grasshopper's eggs, *Aspergillus niger*, *Penicillium Rocheforti*, *Bac. pyocyaneus*), it seems scarcely probable that pig liver juice should differ from beef liver juice in this respect.

A detailed account of our investigation will be given elsewhere.

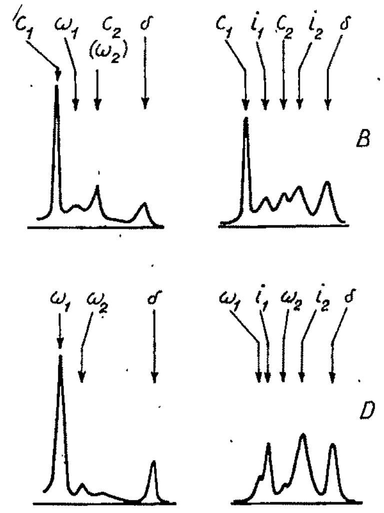
Changes in the Electrophoretic Pattern of Cow's Milk during Early Lactation

DIFFERENCES in composition of colostrum and milk are well known, but with few exceptions have not been thoroughly studied by modern physico-chemical methods. During investigations of milk proteins which are to be published elsewhere, I have also studied samples of colostrum, and milk and whey recovered from these samples in the electrophoresis apparatus of Tiselius. All experiments were carried out in phosphate buffer at *p*H 7·7 and ionic strength 0·1. The diagrams reproduced are from the positive, ascending side of the apparatus. The samples were taken from cow's milk given on the day of delivery and 1, 3, 7 and 37 days thereafter.



In an electrophoresis diagram of milk (*A*), there are two main peaks, c_1 and c_2, corresponding to caseins, and a small one, w_1, corresponding to lactalbumin and lactoglobulin of the whey. (Another peak of whey protein, w_2, is overlapped by c_2.) In experiments with colostrum, diagrams are obtained (*B*) which are quite different from those with ordinary milk. The main difference is the presence of two new peaks, i_1 and i_2, in the case of colostrum. Of these, i_1 is evidently overlapping w_1. During the following days these decrease and the casein fractions come to dominate the diagram. After seven days there is only a very small difference, in comparison with the ordinary milk diagram.

Since the difference between colostrum and milk depends chiefly upon differences of the whey-forming components, whey has been prepared from the milk samples and investigated in the same manner. Diagrams of colostrum whey (*D*) are entirely different from those of ordinary whey (*C*). In the first case, the w_1- and w_2-peaks are very small, and two new peaks, i_1 and i_2, dominate the diagram. The slowest moving of them has been observed by Smith[1] and called 'immunoglobulin'. During succeeding days the picture changes rapidly (*C*), the w_1- and w_2-peaks increasing and the i_1- and i_2-peaks decreasing. As early as one day after delivery the shape of the diagram is markedly changed in this direction. After seven days it is the same as for ordinary whey. Mobility figures for components mentioned are collected in the accompanying table.

Samples investigated	Mobilities of different peaks × 10^5 cm.^{2} volt^{-1} sec.$^{-1}$				
	c_1	w_1	i_1	c_2 and w_2	i_2
Colostrum (*B*)	7·5	—	5·3	4·4	2·1
Whey from colostrum (*D*)	—	(6·6)	5·6	(4·2)	2·0
Milk seven days after delivery (*A*)	7·6	6·7	—	3·8	—
Whey from milk seven or thirty-seven days after delivery (*C*)	—	6·4	—	4·4	—

Thus the difference in protein composition between milk and colostrum is not due simply to an increased proportion of the whey components. Marked qualitative changes in the whey proteins also occur. These changes, as well as the increased protein content, are rapidly transient.

Effect of the Source of Nitrogen in the Medium on the Formation of Penicillin by Surface Cultures of *Penicillium notatum*

A FRACTION which is active in stimulating penicillin formation may be prepared from aqueous extracts of seed peas either dried or green by means of ethanol precipitation[1].

The active ethanol-insoluble fraction, however, must be used at the correct dry matter concentration if consistent yields are to be obtained[2]. Using as a basis the idea that a definite amount of substance must be present in the medium, we tested first the effect on penicillin formation of a number of compounds which either had been isolated from, or might be postulated as occurring in, pea extracts.

Since then we have tested for their effect in stimulating penicillin formation a number of nitrogen-containing chemical compounds which could not be regarded as existing in vegetable extracts.

The results obtained indicate that penicillin formation may be stimulated by diverse chemical compounds.

A basal medium containing 0·3 per cent $NaNO_3$, 0·05 per cent KH_2PO_4, 0·025 per cent $MgSO_4.7H_2O$, 1 per cent NaCl and 3 per cent lactose was made up, and to this the compound under test was added so

TABLE 1

Mould growth as wet weight of mycelium in gm., penicillin formation (units/c.c.) and *p*H developed after 8 days in 40 c.c. medium containing basal constituents, 1·5 per cent glucose and compound under test in amount equivalent to 56 mgm. of nitrogen

Compound	Wet weight of mycelium (gm.)	*p*H	Titre units/c.c.
dl-Norleucine	0·87	7·4	100
l(−)-Leucine	3·14	8·3	240
l(−)-Tyrosine	2·5	7·9	225
l(+)-Cysteine	1·2	6·3	200
Triethylamine	0·88	6·4	160
Uric acid	1·67	6·3	160
Allantoin	1·88	5·3	100
Uracil	1·34	6·5	180
Sodium nitrate	0·60	7·3	150
Potassium nitrate	0·85	7·4	200
Nicotinic acid	1·04	5·4	200
Gelatin	2·0	8·1	190

that the nitrogen content was 56 mgm./40 c.c. medium (that is, 140 mgm. per cent).

The initial *p*H of the medium was adjusted in all cases to 5·6.

Since, when the active fraction from peas was used at its most stimulating concentration, 1·5 gm. per cent of glucose (or its carbohydrate equivalent) was present, this concentration of glucose was added to each compound under test.

In the experiments described *Penicillium notatum* 1249.B21 in surface culture was used, but preliminary experiments with submerged aerated cultures show that similar results may be obtained.

The wet weight of mycelium has been used as a measure of mould growth.

Representative results with various nitrogen-containing compounds are shown in Table 1. Low yields were obtained with the following amino-acids and other nitrogenous compounds: *dl*-tyrosine, *dl*-serine, *l*(−)-cystine, *dl*-aspartic acid, *l*(+)-glutamic acid, *l*(+)-arginine, *l*(+)-histidine, *dl*-tryptophan, *l*(−)-proline, asparagine, trimethylamine hydrochloride, diethylamine hydrochloride, hypoxanthine and potassium thiocyanate. The following nitrogenous compounds had no stimulating effect on penicillin formation although growth in their presence was good: glycine, *dl*-alanine, *dl*-valine, *d*-isoleucine, *dl*-phenylalanine, *l*-dihydroxy-phenylalanine, *dl*-methionine, *dl*-lysine, urea, *n*-propylamine and choline.

The results show that a wide variety of nitrogen-containing compounds has an effect in stimulating penicillin formation, and we cannot relate this stimulating effect to the presence of any definite chemical group in the substances tested.

It will be seen that gelatin forms a good basis for a synthetic medium. Using gelatin as a source of nitrogen, sources of carbon other than glucose have been tested. Typical results are shown in Table 2.

TABLE 2

Mould growth, penicillin formation and *p*H developed after 8 days, in 40 c.c. of medium containing basal constituents, gelatin to give a nitrogen content of 56 mgm., and carbon-containing compounds under test to give a concentration in the medium of 0·6 gm. (that is, 1·5 gm. per cent)

Compound	Wet weight of mycelium (gm.)	*p*H	Titre units/c.c.
Xylose	3·11	7·9	150
Glucose	2·0	8·1	190
Sorbose	1·5	7·9	150
Maltose	2·06	7·9	150
Trehalose	2·03	8·5	260
Raffinose	1·85	8·0	150
Inulin	1·98	7·9	240
Adonitol	1·61	7·7	260
Methyl alcohol	0·66	7·2	0
Ethyl alcohol	1·57	7·8	25
Sodium acetate	0·43	8·8	0
Ethyl acetate	0·46	5·0	0

The results show that when good growth did occur there was marked stimulation of penicillin formation, and that a variety of carbon-containing compounds could be used.

As with the active fraction prepared from peas, the concentration of sodium chloride in the synthetic media had a marked effect in stimulating penicillin formation, as will be seen in Table 3.

TABLE 3

The effect of the concentration of sodium chloride on penicillin formation in the basal medium containing gelatin equivalent to 56 mgm. of nitrogen and raffinose at a concentration of 0·6 gm. per 40 c.c. of medium

NaCl %	Lactose %	Wet weight of mycelium (gm.)	Titre
0·5	3	1·49	50
1	3	1·91	100
2	3	1·54	240

By means of the differential assay, we have found that the type of penicillin formed in most cases was penicillin –X–.

A full account of these investigations will be published elsewhere.

Australopithecinæ or Dartians

WHEN Prof. Raymond Dart, of the University of the Witwatersrand, Johannesburg, announced in *Nature*[1] the discovery of a juvenile *Australopithecus* and claimed for it a human kinship, I was one of those who took the point of view that when the adult form was discovered it would prove to be near akin to the living African anthropoids—the gorilla and chimpanzee[2]. Like Prof. Le Gros Clark[3], I am now convinced, on the evidence submitted by Dr. Robert Broom[4], that Prof. Dart was right and that I was wrong; the Australopithecinæ are in or near the line which culminated in the human form. My only complaint now is the length of the name which the extinct anthropoid of South Africa must for ever bear. Seeing that Prof. Dart not only discovered them but also rightly perceived their true nature, I have ventured, when writing of the Australopithecinæ, to give them the colloquial name of 'Dartians', thereby saving much expenditure of ink and of print. The Dartians are ground-living anthropoids, human in posture, gait and dentition, but still anthropoid in facial physiognomy and in size of brain. It is much easier to say there was a 'Dartian' phase in man's evolution than to speak of one which was 'australopithecine'.

CAREERS IN ZOOLOGY

"CAREERS in Zoology—Possibilities and Training" was the subject of a discussion at the annual meeting of the Association of British Zoologists held in London on January 11. The Council had proposed this topic in an endeavour to provide those responsible for the teaching of zoology in schools, universities and kindred institutions with some guidance on openings likely to be available for young zoologists in the future and what, if any, special directions training should take.

Early in the discussion it became apparent that the field of employment in zoology is clearly divided into two parts: (i) teaching coupled with academic research, and (ii) applied work with research that is, to some extent at least, *ad hoc* and directed. All speakers who alluded to this division expressed their dissatisfaction with its existence, and stated that they believed that for the general health of zoology it is imperative to break down the division as soon as possible. Prof. J. Gray (Cambridge), opening the discussion, emphasized the desirability of encouraging first-class students to enter the applied field, where interesting but difficult problems await solution; increased facilities for fundamental research and a feeling of intellectual freedom are at least as important as high salaries. At present there is little relation between the supply and the demand for recruits; the numbers involved are often small, and no one could afford to undergo specialist training in such subjects as helminthology and protozoology unless assured of a reasonable career. Prof. Gray felt that many existing difficulties would be overcome if there were closer liaison between university teaching departments and institutions undertaking applied studies; he felt that much could be said for extending the principle whereby individuals should occupy simultaneously a university post and an official position under such organisations as the Medical or Agricultural Research Councils.

Dr. F. P. Coyne (Imperial Chemical Industries, Ltd.) suggested that what industry and commerce require of the entrant into the field of applied zoology is not that he be a ready-made specialist, but that he have a capacity for clear thinking. The idea that he need have an encyclopædic knowledge of a special field, or of the whole of zoology for that matter, is found among non-applied zoologists but not among those already in the applied field. Beyond a general training in zoology, the best additional qualification for applied work is probably a degree or diploma in agriculture. An acquaintance with statistical methods is also desirable, first so that the output of statistical departments can be appreciated, and secondly that experiments can be planned from the beginning in a form that will give results that statisticians can readily deal with. This does not, of course, mean that the zoologist should attempt to become a fully developed mathematician.

Prof. C. H. Waddington (Edinburgh) began his observations by pointing out that while Britain had, at one time, led the field in genetics, the subject has latterly fallen behind somewhat, and the main developments have been taking place elsewhere. Genetics cannot be purely a study of breeding experiments, but successful research is dependent on parallel advances of knowledge in the physiology of plants and animals, and in the analysis of exactly what factors contribute toward the qualities of plant or animal that it is desirable to improve. He illustrated this by pointing out some of the many factors that contribute toward a satisfactory milk-yield in dairy cows. Another field in which advances are due to be made is that of genetics in relation to general evolutionary processes. Prof. Waddington suggested that genetics should be more integrated into the general subject of analytical biology, and the past tendency towards the separation of genetics from zoology should, if possible, be reversed. Future laboratories of genetics will require zoologists as well as specifically trained geneticists.

Speaking of fisheries research and work on marine biology generally, Mr. Michael Graham (Fisheries Laboratory, Lowestoft) pointed out that while proposed developments may lead to an average intake of some two or three individuals every year, this could not be expected to be a regular intake owing to inevitable inequalities in age-groups employed. He therefore suggested that while an individual student might well train for fisheries or other marine research, if aptitude had been shown, he would be well advised to have a good alternative subject, with which to seek employment should openings in fisheries and related work prove to be few and far between. Mr. Graham pointed out that it is now possible to gain some information about the financial side of careers in zoology by reference to the White Paper on the Scientific Civil Service, since the conditions laid down therein apply to work undertaken or supported by Government institutions, and would certainly be used as a guide by the majority of research stations.

An interesting account of developments in the relatively small field of research on the anti-fouling of ships was given by Prof. J. E. Harris (Bristol). He pointed out that while this work will be almost certain to continue, it cannot be expected to absorb a large number of zoologists. Prof. Harris emphasized that this applied work brings the research worker into contact with fundamental problems of marine biology; and that those who control financial aspects are becoming convinced that the division between the applied field and the non-applied is, perhaps, much less apparent in this field than elsewhere.

Dr. E. L. Taylor (Veterinary Laboratories, Weybridge), discussing veterinary science generally and helminthology in particular, pointed out that work in these fields tends perhaps to overlap into other fields to a greater extent than any other type of work in which zoologists normally find employment. However, it would not be desirable to add pharmacology, for example, to the zoologist's equipment; but perhaps the general subject of parasitism in all its manifestations, and including immunity, might receive more attention in the general training of zoologists. Dr. Taylor stressed the fact that the fundamental approach to the problems of parasitic diseases is ecological, since all these diseases are, on final analysis, the result of man-made derangements of environment. Losses due to parasitic disease are enormous, and it is to be hoped that, in future, zoologists, even if in limited numbers, may find employment in this field.

The field of employment before the young entomologist was analysed by Dr. V. B. Wigglesworth (Cambridge). It consists—with exceptions, of course—of a limited number of openings in teaching, which is in fact part of pure zoology; a limited number in systematic entomology or museum work; and a much larger number in applied work. An applied entomologist is primarily an investigator, and he is not fully trained until he is acquainted with the industry which he serves. University training should therefore aim at a synthesis of insect morphology, physiology and taxonomy, and afterwards a year or two of research. In addition, the applied entomologist will require at some stage a training or a period of apprenticeship in the industry which he is to serve. Dr. Wigglesworth concluded by enumerating some of the very diverse organisations wherein entomologists can seek employment if prepared to carry out applied work.

In the general discussion among members which followed the introductory papers, a number of points were made. It was suggested that biology, and therefore zoology, is now such a complex subject, with roots deep down in chemistry, physics and mathematics, that certain preliminary training in these subjects should be insisted upon before work in zoology itself is commenced at any other than a most elementary level. Such training is required for medicine; why should zoology exempt its trainees from being of a certain educational standard in such very relevant subjects? The great need for systematic zoologists was mentioned, but the opinion was expressed that systematists gradually develop in the course of general zoological training, and few, if any, could be specifically trained for taxonomic work. In any event, systematics is a very specialized field, and a relatively small one compared with the rest of the general field of zoology.

One speaker suggested that the rising cost of living, along with the relatively poorer career prospects in biology, is leading to an ever larger number of potential zoologists taking up medicine rather than zoology; but this point of view was immediately controverted by another speaker.

The fact that zoologists appear to have succeeded in a great number of non-zoological war jobs was cited as showing that zoology as a discipline has very considerable educative value, as distinct from being a subject of training in a specific technical field, and that it is desirable that this should be stressed. To speak of 'training' in zoology implies in itself that the trainee is to become a professional zoologist. No one would talk of a 'training' in classics, but an 'education' in classics was held to fit a man for almost any job where administration is involved. Is there anything that makes the man 'educated' in the classics or such similar subjects automatically a better potential worker than the man 'trained' in zoology?

JOHN SMART

MODERN METHODS OF FIBRE INVESTIGATION

STUDIES on the properties of single fibres have been particularly successful in increasing our knowledge of the structure of natural and synthetic high polymers and of the basic principles underlying many industrial processes. Special techniques have been developed to overcome the experimental difficulties involved in making measurements on single fibres, and many of these methods were discussed at a Conference on Single Fibre Testing held by the Textile Institute in the University of Leeds on January 29. The February issue of the *Journal of the Textile Institute*, in which the papers read at the Conference are published, forms a valuable addition to scientific literature, and will be a useful practical reference volume for all who are interested in this field of investigation.

Determinations of breaking load, extension at break, and other elastic properties which have attracted many workers were discussed by R. Meredith, and an instrument designed by J. Sikorski, C. S. Whewell, and H. J. Woods was described in detail on account of its having proved satisfactory for making such measurements over a period of ten years. Interest in studies on bending has recently been intensified, and measurements of bending modulus may be made simply by the use of apparatus described by P. Carlene and by L. G. Wilson. R. H. K. Thomson and D. Traill gave an account of an apparatus designed to assess the resistance of fibres to repetitive bending—a property which is equally important, although some doubt was expressed as to the correlation between results obtained by this method and those obtained on material in bulk. Deformation of fibres by shearing stresses was considered by A. Finlayson, and papers by R. Meridith and by W. E. Morton and F. Permanyer supply details of satisfactory methods for measuring torsional rigidity and torsional relaxation, which are particularly significant in relation to the spinning of textile fibres. Determination of axial swelling by direct microscopic observation is slow and difficult, especially with fibres of varying and irregular cross-sections, but new methods of measurement devised by J. M. Preston and S. Das Gupta and by F. L. Warburton are much simpler.

Other fibre properties, less frequently studied, were the subjects of a contribution by J. M. Preston on the refractive index of textile fibres, and an interesting account of preliminary experiments by G. E. Collins on the surface tension method for measuring the perimeter of a fibre and the contact angle.

Weighing the single fibre is a necessary operation in most investigations, and has in the past been done by using torsion balances. These instruments are delicate and often lack stability, but the cantilever microbalance of E. Lord is more robust and stable, and is very suitable for routine work.

Sampling is one of the most important aspects of single fibre testing, and statistical analysis of the results is in most cases necessary. These topics were discussed by R. C. Palmer and H. E. Daniels, who illustrated their contribution by reference to the measurement of fibre length. The value of modern single fibre testing is possibly best illustrated by the results which have been obtained on animal fibres, for although opinions may differ on the detailed interpretation of certain observations, studies on the properties of natural and chemically modified animal fibres under various conditions have been particularly successful. Some of this work was described by J. B. Speakman, who gave a lucid account of the uses of load/extension curves, set, and supercontraction in the routine control of wool textile processes as well as in research on the chemistry of animal fibres. The new techniques developed by R. D. Preston and by F. Happey and A. W. Porter for obtaining X-radiograms of single fibres should also prove valuable in investigations on the structure of fibres.

FORTHCOMING EVENTS

Saturday, March 22

BRITISH INSTITUTE OF RADIOLOGY (at the French Institute, Queensberry Place, London, S.W.7), at 10.15 a.m.—Prof. D. W. Smithers: "The Radiotherapist and the Cancer Patient" (Presidential Address); at 2 p.m. (at the Royal Cancer Hospital (Free), Fulham Road, London, S.W.3).—Demonstrations.

Monday, March 24

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Dr. J. A. V. Butler: "Enzymes—their Isolation, Structure, Mode of Action and Place in Nature" (Cantor Lectures, 3).

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.15 p.m.—Mr. F. E. Brown: "Engineering Economy in the Rubber Factory".

ROYAL STATISTICAL SOCIETY, SHEFFIELD BRANCH of the INDUSTRIAL APPLICATIONS SECTION (in Room B1, Department of Mechanical Engineering, The University, St. George's Square, Sheffield), at 6.30 p.m.—Mr. K. A. Brownlee: "The Value of the Factorial Experiment in Chemical Investigations and its Development".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON STUDENTS' SECTION (joint meeting with the ASSOCIATION OF LONDON STUDENTS OF THE INSTITUTION OF CIVIL ENGINEERS and the LONDON GRADUATES' SECTION of the INSTITUTION OF MECHANICAL ENGINEERS, at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Short papers on "Hydro-Electric Power Schemes".

INSTITUTE OF BRITISH FOUNDRYMEN, SHEFFIELD BRANCH (at the Royal Victoria Station Hotel, Sheffield), at 7.30 p.m.—Mr. G. W. Nicholls: "Machine Tool Castings".

Tuesday, March 25

FEDERATION OF BRITISH INDUSTRIES (at the Queen's Hotel, Birmingham).—Conference on "Industry and Research". At 10 a.m.—"Research and Economic Recovery"; at 2 p.m.—"Industrial Research in the Midlands".

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Sir Theodore Tasker: "Prehistory and Anthropology in the Hyderabad Deccan".

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7 p.m.—Mr. H. Wrighton: "Reflections on War-time Steel Inspection".

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. R. Meakin: "Electronics in Non-destructive Testing".

Wednesday, March 26

PHYSICAL SOCIETY, COLOUR GROUP (at the Royal Photographic Society, 16 Princes Gate, London, S.W.7), at 3.15 p.m.—Mr. M. E. Clarkson, Dr. O. L. Davies and Dr. T. Vickerstaff: "A Statistical Investigation of some Aspects of Colour Harmony".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Dr. A. J. Turner: "Flax Utilisation".

SOCIETY OF CHEMICAL INDUSTRY, NUTRITION PANEL (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. Kenneth Mellanby: "Human Water Requirements" (all members of the Food Group are invited).

INSTITUTION OF NAVAL ARCHITECTS (at 10 Upper Belgrave Street, London, S.W.1).—Annual General Meeting.

Thursday, March 27

MINERALOGICAL SOCIETY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

ROYAL AERONAUTICAL SOCIETY (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Air Vice-Marshal E. B. Addison: "The War in the Ether".

SHEFFIELD METALLURGICAL ASSOCIATION, REFRACTORIES GROUP (at 198 West Street, Sheffield), at 7 p.m.—Mr. J. E. Pluck: "Open Hearth Refractories and Insulation".

TEXTILE INSTITUTE, BELFAST SECTION (at the College of Technology, Belfast), at 7.30 p.m.—Dr. R. G. Fargher: "Trends in the Continuous Processing of Textiles".

Friday, March 28

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5 p.m.—Annual General Meeting. Mr. J. A. Sumner: "The Norwich Heat Pump"; Mr. T. F. Thomas: "The Air Cycle Heat Pump".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Harold Spencer Jones, F.R.S.: "Eclipsing Variable Stars".

Tuesday, March 25—Friday, March 28

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2).—Convention on "Radiocommunication with particular reference to War-time Activities and their possible Influence on Peace-time Development".

Tuesday, March 25

At 5.30 p.m.—Sir Stafford Cripps, P.C.: Opening Ceremony. Colonel Sir Stanley Angwin, K.B.E.: "Telecommunications in War".

Wednesday, March 26

At 9.45 a.m.—"Long Distance Point-to-Point Communication"; at 11.30 a.m.—"Naval Communication"; at 2.30 p.m.—"Military and Aeronautical Communication"; at 6 p.m.—"Pulse Communication".

Thursday, March 27

At 9.45 a.m.—"Short-Distance Communication" (1); at 11.30 a.m.—"Short-Distance Communication" (2); at 2.30 p.m.—"Direction-Finding"; at 6 p.m.—"War-time Broadcasting".

Friday, March 28

At 9.45 a.m.—"Propagation"; at 2.30 p.m.—"Radio Components"; at 6 p.m.—Sir Clifford Paterson, F.R.S.: "Review of the Convention and Future Trends".

Wednesday, March 26—Friday, March 28

INSTITUTION OF NAVAL ARCHITECTS (at the Royal United Services Institution, Whitehall, London, S.W.1).—Eighty-eighth Annual Meetings.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR ATTENDANT (Grade A Technician, male or female) to take charge of the small-animal colony—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (March 31).

LECTURER IN TEXTILE CHEMISTRY—The Registrar, College of Technology, Manchester 1 (March 31).

LECTURER IN CHEMISTRY—The Secretary, The University, Aberdeen (April 4).

SOIL CHEMIST, and a MYCOLOGIST, in the Kenya Forest Department—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1 (April 5).

CHAIR OF ZOOLOGY—The Secretary, The University, Edmund Street, Birmingham 3 (April 14).

CHAIR OF PHONETICS tenable at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 15).

AGRICULTURAL CHEMIST in the Nyasaland Department of Agriculture—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1 (April 15).

DEWAR RESEARCH FELLOWSHIP, tenable in the Davy Faraday Research Laboratory—The General Secretary, Royal Institution, 21 Albemarle Street, London, W.1 (April 15).

LECTURER IN THE DEPARTMENT OF PHYSICS—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (April 24).

PROFESSORS (2) OF MATHEMATICS (one with special qualifications in Hydro- and Aerodynamics, the other in Statistics)—Prof. S. Beatty, Department of Mathematics, University of Toronto, Toronto, Canada (May 1).

FELLOWSHIP associated with the memory of the late Mr. E. B. Stringer—The Bursar's Clerk, King's College, Cambridge (May 1).

DEVELOPMENT COUNCILS IN INDUSTRY

THE anticipated Bill to give effect to the recommendations of the reports of the 'working parties' set up by the Board of Trade, and particularly to provide for the use of a compulsory levy to support scientific research, has now been published and received its second reading in the House of Commons on February 13. The debate on this Industrial Organisation Bill, however, scarcely touched on the issues which are disturbing to those most closely concerned with research, and it is to be hoped that its clauses will receive much more searching and constructive criticism when the Bill reaches the House of Lords. In spite of the fact that all the reports so far received from the 'working parties' have favoured a compulsory levy, it is by no means certain, as Mr. I. J. Pitman and Mr. W. Shepherd pointed out in the House of Commons, that duress will prove more effective than persuasion for the purpose in mind.

The Bill enables any of the ministers specified in the Bill, including the President of the Board of Trade, and the Ministers of Agriculture and Fisheries, Supply, Food, and Fuel and Power, after consultation with organisations of workers and employers in an industry, to establish a development council for that industry. The general objects of such councils are to increase the efficiency and productivity of the industry concerned, and to enable it to render better and more economical service to the community. For this purpose a development council may be authorized to promote or undertake scientific research or research into industrial psychology, the incidence, prevention and cure of industrial disease, the marketing of products, or the consumption or use of goods and services supplied by the industry. A council may also be empowered to promote inquiry into materials and equipment, methods of production, management and the utilization of labour, the improvement of design, the production and marketing of standard products, the training of personnel and improvement of working conditions as well as the collection and formulation of statistics. A council may also be authorized to collect a levy to finance its activities, the maximum rate of such levy being laid down in the order establishing the council. These orders must be first approved in draft by both Houses of Parliament, and the main features of the constitution of the councils are determined in the Bill, which provides for the appointment of their members by the minister concerned, and that they shall consist of persons capable of representing the interests of employers and workers in the industry, with independent persons, one of whom will be appointed chairman by the minister. There are rigid restrictions on the disclosure by members of a council, or its officials, of information relating to individual businesses, and a further clause empowers the minister concerned to collect a levy from an industry for which no development council exists, if he considers it necessary that finance should be made available for the promotion of scientific research, the development of exports or the improvement of design in that industry. The Board of Trade is also empowered to make grants to the Council of Industrial Design or to any other non-profit-making body the objects of which include the improvement of design in industry.

In moving the second reading, the President of the Board of Trade stressed the importance of flexibility in applying any pattern of organisation, and did not suggest that it would be desirable to deal with every industry under the Bill. But while he was careful to avoid any suggestion that the work of the joint industrial councils should be disturbed, and insisted that production and development matters should be kept separate from negotiations as to wages and conditions of work, the first criticism that will be made, apart from the question of the validity of compulsion, by the scientific worker at least, is that the activities of the development councils may overlap seriously within their own ranks and with one another. That criticism was indeed advanced in the debate by Mr. Mikardo and by Mr. Mallalieu. Admittedly, many of the functions scheduled in the Bill are appropriate for co-operative effort and even demand it. The question is rather whether that effort should not be made on an even wider basis than the limits of a single industry.

That very clearly may be true of such matters as industrial psychology, where it might be thought that to develop the work of the National Institute of Industrial Psychology is the appropriate means to adopt. Again, as regards industrial health and disease, it might equally be argued that further support should be first extended to the Industrial Health Research Board, while as regards management and training there is much to be said for encouraging the work of the Institute of Industrial Administration or the new British Institute of Management, rather than fostering new and unrelated sectional activities in the same field. Mr. Mallalieu and Wing-Commander Shackleton in particular were concerned with the danger of dissipating effort here, and the former also observed that the improvement of working conditions, even the 'spring-cleaning programme' advocated by the Chief Inspector of Factories in his last report, is essentially a matter for Government assistance with priorities in materials and labour. On the question of research, the Bill encourages no more confidence than the reports of the 'working parties' themselves, several of which have shown a most inadequate appreciation of the nature of research and the conditions for its effective prosecution.

That point indeed did not entirely escape notice in the debate. Mr. Rhodes asked specifically how the Bill was related to the grants from the Department of Scientific and Industrial Research and also to the grants from the Council of Industrial Design. Mr. Belcher, replying for the Government, stated that development councils would work through, and would not supersede, research associations and design centres. Contributions to these bodies from a development council's research levies would count as industrial contributions and would be eligible for the appropriate Government grants from the Department of Scientific and Industrial Research in regard to research and from the Board of Trade in regard to design. Sir Stafford Cripps had also earlier disclaimed any idea of compulsion in regard to research. Here a development council could help and advise; but its compulsory powers, when granted, were to be limited to the collection of statistics, the registration of persons in industry and the collection of a levy.

Sir Stafford Cripps was more concerned with the danger that the councils might be liable to try to adopt and encourage restrictive practices, which would be inimical to the consumer and to the general national welfare. That danger may be inherent in bodies the members of which are representative of an industry, rather than chosen with a view to the fitness of the individual member for the job to be done. Although Sir Stafford indicated the Government's intention to take active steps to stop the encouragement of restrictive practices by a development council, that is not an easy task in practice, nor is there any certainty that other Governments would be equally concerned to try. Moreover, there is an equally serious danger to which Mr. Pitman referred in the able speech already noted, namely, that of industry tending to shuffle the responsibility for dealing with its problems on to the development councils.

Such a tendency can be seen in the trend of some of the reports from the 'working parties', and it is well illustrated by the coal industry at the moment. Something of the acuteness of the fuel crisis might well have been mitigated had, for example, more note been taken of such reports as that on "Coal Utilisation Research and the National Economy" which the Parliamentary and Scientific Committee forwarded to the Lord President of the Council in May 1943. It was left to Lord Marley to direct attention to this factor in the debate on the coal situation in the House of Lords on February 13. Referring to the inefficient utilization of coal and the waste of coal resources by industry, Lord Marley cited not only the work of the British Coal Utilisation Research Association, the British Colliery Owners' Research Association, the Gas Research Board, the Fuel Research Station and other stations of the Department of Scientific and Industrial Research, but also an important report in 1943 from the Select Committee on National Expenditure; from all these sources many recommendations had been made for the saving of coal in the production of power and heating of buildings and plant, but industry had neglected them. This picture of twenty years of neglect of available knowledge and wasted national assets should give pause to any elaborate proposals for development from outside. The results of research will only be utilized when management, particularly in the smaller firms, becomes research-minded, and that change of outlook will often of itself induce the undertaking of research by such firms.

The prosecution and utilization of research by industry depend fundamentally, as we have so often urged, upon having men with the scientific outlook and training on the boards of management and directors, and there is no short cut which can wisely be taken to avoid the slow task of education and persuasion. It is not easy at first sight to see what more the development councils could contribute here that existing organisations could not already supply. It is true that they may do good in different directions; on the other hand, they may do little to justify their cost and may still discourage private initiative. Any element of compulsion in relation to research is to be distrusted on *a priori* grounds, and only used as a last resort. Where persuasion by other means is possible it should be tried, and such opportunities of indirect stimulus to research as we once had under the Import Duties Advisory Committee should not again be missed.

Everything, in fact, will depend on the membership and staff of any development councils, and the extent to which the idea, not of sectional represention of one side of an industry or another, or of one set of private interests rather than another, but of the welfare of the industry as a whole and of the service of the community, sets the standard for their policy and administration. It is a question of men rather than of organisation, and in setting up such councils the Government will do well to press forward by every means in its power those developments such as the British Institute of Management which promise to increase the supply of trained administrators and managers, qualified to appreciate and assess advances in science and to apply them to the purposes of the industry in which they are engaged. None the less, it is important that the organisation which the Bill proposes to establish should be subjected to a most careful scrutiny, such as Mr. Pitman also suggested, to determine how far it is in keeping with the cardinal principles of organisation on which any such scheme must be based. Mr. Pitman indeed, from his experience as director of the Organisation and Methods Division of the Treasury, believes that departure from the voluntary principle is a fatal defect in a body in which the co-operation of employers, management and workers is involved; and the danger of an overlap of functions and responsibility which was stressed from both sides of the House in the debate indicates the need for a close examination of such relations, for clearer definition of functions as between the industries and various national functional bodies. What is certain is that failure to serve sound administrative principles in the organisation of the councils and in defining their functions will be a fatal obstacle in attracting to their service the first-class men who are indispensable to the success of the whole scheme. Whether or not the development councils can do anything that the joint industrial councils could not equally well foster, it appears essential that their compulsory powers should be used both with restraint and discretion. It is equally important that care should be taken to see that they involve no further dissipation or waste of our precious resources of trained man-power, either in the scientific or in the technical field.

PRE-NATAL PHYSIOLOGY

Researches on Pre-Natal Life

By Sir Joseph Barcroft. Vol. 1. Pp. xiii + 292. (Oxford: Blackwell Scientific Publications, Ltd., 1946.) 37*s.* 6*d.* net.

THIS book is the first of its kind; it may be described as a work on physiological ontogeny; that is to say, it deals with the development of function in the progress of fœtal life. Moreover, it keeps in view throughout, not only the intra-uterine conditions under which the fœtus lives and grows, but the fact that the fœtus will eventually pass out into the world and in such a state that it can respond successfully to its new environment. The book deals mainly with investigations by the author himself and his colleagues and pupils in the Schools of Physiology and Agriculture in Cambridge. It does not claim to be a text-book on the subject, and so does not include such work as has been done in other centres like that on the initiation of the heart beat carried out at the Johns Hopkins University. Nevertheless, it covers very considerable ground, and the relevant papers by other investigators are duly quoted. The researches were mostly upon the fœtal sheep, and it is impossible to refrain from an expression of admiration for the ingenuity of the investigator and for the results which he obtained, especially when one bears in mind the great difficulty that must have been experienced in dissecting fœtal lambs so as to preserve any considerable degree of normality. Wherever possible the author has correlated his observations and those of others so as to give a connected story of the physiological events studied. But he very wisely does not always attempt this, and at the beginning of the chapter on the oxygen capacity, he says frankly that he decided to record a series of unconnected observations rather than to arrange them under some hypothetical scheme. For here, as in other parts of the book, the facts are not only interesting but also beautiful in themselves, and need no scientific hypothesis to make them more so.

The first two chapters are on the disposition of vessels in the placenta and the crossing of the placental barrier, and the author begins with a comparison between placental and fœtal growth in the sheep; and it is shown that whereas the fœtus puts on weight every week, the cotyledons of the uterus, after reaching a maximum at about ninety-five days, proceed to decline. It is not clear how much the maternal growth during pregnancy depends upon the fœtus, and it is known that some uterine development (at least in certain species) occurs after ovulation in the absence of a fœtus. With regard to the matter of permeability the author finds that, contrary to the views of Flexner, the greater the number of layers in the fœtal barrier, the more perfect is the fœtus at birth, and he instances the horse with a six-layer placenta, quoting an experience of Hammond, who found that a newly born foal was so perfect at birth that it ran away promptly and could not at first be caught. The author emphasizes that though the several types of placenta differ much, they all serve their purpose in their own way, but that the great surface which among other varying devices promotes the passage of material across the fœtal membrane is present in all forms of placenta. The passage of oxygen from the mother to the fœtus is simply one of diffusion, as Huggett and others have concluded. It is shown, further, that fatty food substances vary with the maternal ones, but that sugar in sheep and goats is present in greater quantity in the fœtal blood than in the maternal. The author quotes experiments by Passmore and Schlossmann showing that by injecting glucose into the mother the glucose content of the fœtal blood can be raised. The deduction seems clear, both in the case of fats and sugars, that by altering the diet of the mother the food contents of the fœtus may also be modified, and this is a conclusion of great practical importance for breeders of farm animals.

The next chapters, on growth, contain interesting comparative studies, and Hammond's observations on the pig are quoted, showing that embryos perish *in utero* and at varying stages of development, and that this is not usually due to overcrowding, for it may occur in any part of the uterus. The work of Wallace and that of Carlyle is referred to, showing that the various organs of the fœtus undergo their maximal development at different times; even within the same organ (for example, the gut) the different parts have their critical periods of growth, and bones develop at different rates. At birth, blood is one of the four bodily constituents of major weight, the other three being skin, skeleton and muscle. The last three or four weeks of pregnancy are the great blood-forming period. The question arises as to whether, at specific times during gestation, special foods should not be fed to the mother. This question, together with the more general one of the relations between maternal nutrition and fœtal development, is dealt with again in Chapter 5, which concludes by remarking on the special importance of this subject in the present age when the possibility of semi-starvation is confronting a large part of the world. The author quotes Hammond, who has shown in his experiments on pigs and rabbits that the larger and better nourished the mother the larger are the young; and Wallace has proved quite definitely for the sheep that by altering the diet of the mother one can influence the growth of the offspring. Nevertheless, the fœtuses may have their own intrinsic growth mechanisms which vary from individual to individual.

The seventh chapter is upon the transfer of blood from the placenta to the fœtus at birth, and numerous experiments involving the tying or clamping of the umbilical cord are described. It is shown that the average amount of blood transferred was 120 c.c. or 39 c.c. per kilo, which is not very different from that found in man. The presumption is that the blood is expelled as a result of the umbilical and placental vessels contracting.

The water content of the fœtal tissues is next dealt with, and then the basal consumption of oxygen of the tissues of the sheep fœtus at different ages. The cardiac output is the subject of the tenth chapter, and it is shown that this is much greater towards the end of pregnancy.

The following chapters are on blood pressure and the development of vascular reflexes, and in reading the accounts of the several experiments one is impressed by the difficulties involved but successfully overcome in applying a difficult technique. That there should be great variability in the different species was to be expected in view of the varying degrees of development at birth. Among other interesting points, it is shown that the venous pressures do not rise like the arterial ones, but remain fairly constant after the fiftieth day. Slowing of the heart beat by vagus stimulation could occur on the seventy-seventh day in the sheep. The pulse-rate was found to become progressively slower after the ninety-third day. In the chapter on the oxygen dissociation curve the subject is complicated by the fact that there are two sorts of hæmoglobin, the myohæmoglobin of muscle and that found in normal blood. In the earlier stages of fœtal life hæmoglobin is made very largely in the liver, and this may give rise to myohæmoglobin.

In the chapter on acid-base equilibrium and carbon dioxide dissociation curves the work of Huggett and Keys is dealt with, and it is shown that the carbon dioxide pressure is almost certainly higher in the fœtal than in the maternal blood, and that the hydrogen ion concentration of the fœtal blood is less than that of the maternal. Further, Keys found that the dissociation curve of a pregnant goat was below that of the control, but the fœtal dissociation curve as compared with that of the mother might be either above or below. In the chapter on the oxygen in the umbilical vessels the fact emerges that while all other factors fluctuate widely the oxygen content in the umbilical vein is almost constant. The author comments on the similarity between the oxygen content of the blood in the umbilical artery and that in the thoracic vena cava. Later, he gives the evidence that there is a sphincter at the umbilical end of the ductus venosus which contracts after delivery. Another point of interest is that the foramen ovale is not 'just a hole', for as shown by Barron and by Franklin, it constricts with each heart beat. In the nineteenth chapter the author shows that the view taken by Wolff a hundred and fifty years ago, that the streams of blood which reach the right side of the fœtal heart do not completely mix, is correct. Kennedy and Clark are quoted as demonstrating that oxygen, and not just any gas, causes the closure of the ductus arteriosus, and that this does not result from nervous stimulation.

Chapter 21 is on the respiratory process, and it is shown that this is very efficient for the fœtus, at least up to the 120th day, since the vascular bed in the placenta is large. Later, the conditions deteriorate as the end of pregnancy draws near, and "the fœtus is approaching a crisis . . . the alternative between death and escape". The last chapter deals with the onset of respiratory movement, and the author describes how at halfway through gestation in the sheep the fœtus, after having been temporarily inert, is already capable of making normal respiratory movements as a result of occluding the umbilical cord, though it cannot breathe if only because the lung is solid.

The high degree of perfection to which the fœtus has attained in co-ordinating its functional activities in the progress of growth and development must be a matter of constant wonder to the investigator, and one is reminded of the words of Samuel Butler: "Birth is the end of the time when we really knew our business, and the beginning of the days when we know not what we would do, or do".

The volume is dedicated to D. H. Barron, with whom the author collaborated in so many of his researches. In a brief notice such as this only a very few of the observations recorded have been quoted, and it has been difficult to make a selection. The book needs to be read in order that its scope may be realized and its originality appreciated. It is to be followed by a second volume dealing with the nervous system and the principles of metabolism.

F. H. A. MARSHALL

AGRICULTURAL BOTANY

Principles of Agricultural Botany

By Dr. Alexander Nelson. Pp. xvii+556+128 plates. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1946.) 35*s*. net.

THE publication of a new text-book of agricultural botany is something of an event, since only one has been available hitherto. This paucity is due to two main reasons. First, agricultural botany scarcely exists as a unitary subject in the United States and most other countries, its content being subdivided and variously allocated. Secondly, the need for a text-book has previously been met by Percival's "Agricultural Botany", which has run into eight editions and been translated into various languages. This book, first published in 1900, was a remarkable pioneer work which appeared in its last edition only ten years ago. But, during the past three decades, the approach to the subject of agricultural botany has changed, the content of the subject has expanded and acquired new orientations, and the outlook of agricultural botanists has developed in relation to advances in 'pure' science and in agricultural science and practice. Percival's book, valuable as it is and in many ways still indispensable, has changed but little in its successive editions, and there is need of a treatise reflecting the modern state of agricultural botany that will serve teachers and students to-day as well as Percival's volume served those of earlier years. Nelson's "Principles of Agricultural Botany" must be viewed against this background.

One is, perhaps, a little disturbed by the title of the book. Agricultural botany is not an autonomous science; it is merely the diffused area of scientific knowledge which forms the meeting-ground of botany with various other sciences and empirical practices. Its content and boundaries are determined by the sole criterion that the plants with which it deals are, in their crop husbandry relationships, useful or harmful to man. The principles involved in its study are principles of botany and certain cognate sciences, not of agricultural botany.

The book is organised in four sections: morphology and anatomy; physiology; negative factors in food production; and heredity, evolution and classification. Section 1 opens with a chapter on "Food in General" which might better have been placed in section 2. The author then discusses the elements of plant form and structure, which leads to an exposition of the modifications of 'standard type' seen in agricultural plants. A discussion of the elements of plant reproduction similarly leads to a detailed consideration of the special aspects of the inflorescence, flower, fruit and seed of these plants. The student thus proceeds from certain general principles of botany to special examples chosen from agricultural botany, and, by the end of section 1, has acquired a considerable amount of information concerning crop plants. In section 2, principles and technical data are more closely interwoven. Much modern physiological research of a fundamental nature has been carried out on economic plants, and the author can thus illustrate his exposition of principles by direct reference to crop plants and agricultural conditions. There is, however, the same general trend from principles to special information, the introductory chapter, which some agricultural students may not survive, dealing with abstruse "Fundamental Concepts", while the section closes with a purely technical chapter on "Pasture". Section 3, in both contents and text, is headed "Weeds; Insect Pests; Disease", but the four chapters give a brief account only of weed biology and control and of diseases caused by environmental factors, viruses, fungi and bacteria. The student is again introduced to certain relevant principles; but he acquires little of the technical knowledge of these subjects expected of a well-trained agricultural botanist. Section 4, on "Heredity, Evolution and Classification", contains only two chapters, which give a still briefer and less adequate account of these subjects.

Thus, the general balance of the book cannot be regarded as satisfactory and, in view of the fundamental importance in agriculture of the subject-matter of sections 3 and 4, the author's admission in his preface that "it may appear that some subjects have received rather cavalier treatment" would seem more correct than his claim that "Nevertheless, matters of botanical interest significant in agriculture have received adequate treatment". Further, the author's discussion of his subject-matter is very unequal, section 1 being written at about agricultural college level, section 2 at about university level, and the last two sections at about farm institute level. Certainly, from my experience of examining in various universities, the book does not substantiate the author's claim that it assembles "all the information likely to be required by you when preparing for a formal examination in Botany, leading to a degree or diploma in Agriculture". Moreover, although, on the whole, the text is simple and straightforward, there are many awkward sentences, some statements that are ambiguous or dubious, others that are positive misstatements and, occasionally, some serious errors. Further, in many respects, the author's treatment of his material is not up to date.

One of the most disturbing features of the book is the author's adoption throughout of vernacular names of plants, scientific names being virtually absent. This, in spite of the fact that he recognizes that "Unfortunately, these 'common' names differ in different districts or areas. . . . A name universally used for the same species all the world over is required. Science is international, and scientists must be able to write and speak about a plant so that scientists everywhere can understand just what particular plant is meant." In these days, when even school-children and growers are becoming familiar with the scientific names of plants and appreciative of the reasons for their usage, Dr. Nelson's practice seems incomprehensible. Each chapter closes with a short list of books for further reading and, apart from misspelling of authors' names and errors in citation, these lists are often unsatisfactory.

The format of the book is almost that of an 'edition de luxe', and it contains 182 text-figures, 128 half-tone plates and 17 plates in colour. Many of these illustrations are original and most of them are of high quality, although there are some bad lapses, and one can understand the author's grateful acknowledgment to his publishers "whose enthusiasm has made the book possible". On the other hand, the sumptuous format, practically all the coloured illustrations, very many of the half-tone plates and many of the text-figures are entirely unnecessary, and a more restrained enthusiasm might have produced an equally useful book at a much lower price. Most agricultural students will look several times before paying thirty-five shillings for a text-book that covers inadequately only a portion of their course in agricultural botany. The author had a great opportunity, and one can only regret that he has not made the best use of it.

W. B. Brierley

PHILIPPINE BIRDS

Birds of the Philippines

By Jean Delacour and Ernst Mayr. (Pacific World Series.) Pp. xv + 309. (New York: The Macmillan Company, 1946.) 18*s.* net.

In a foreword to this volume, Prof. Fairfield Osborn explains that it is one of a series brought out under the auspices of the American Committee for International Protection of Wild Life. The object of this series, which deals with all branches of animal life and plants, is to make known to the public "the wonder and beauty of natural things" and create a desire to protect and conserve the fauna and flora of the islands of the Pacific and neighbouring lands. Much of the pioneer work on the avifauna of the Philippines was done by two famous English collectors, A. H. Everitt and John Whitehead, and the Marquis of Tweeddale made the birds of these islands his special study. Macgregor's "Manual" was for long the standard authority, and some eleven years ago Hachisuka commenced an ambitious work, of which not more than five parts appeared—but like all that writer's work it is a mere compilation.

This volume now brings our knowledge up to date in a very condensed form and is a valuable addition to the ornithological literature of the area. It is unfortunate, however, that more space has not been devoted to the habits and biology of the different species, which are of more interest to the general reader than the details of subspecies. Then, too, in the chapter on the bird geography of the islands the entire absence of English names is apt to be rather disconcerting to the general reader. To the student of geographical variation the book supplies much useful information, and nowhere can this subject be better studied than in the Philippine Islands. Take, for example, the striking crimson-backed woodpecker, *Chrysocolaptes lucidus*, of which there are no fewer than six well-defined races differing in colour.

These islands are the home of the magnificent monkey-eating eagle, *Pithecophaga jefferyi*, first discovered by John Whitehead. They are specially rich in pigeons, cuckoos and kingfishers, the last ranging from the rather ungainly stork-billed kingfisher to the brilliantly coloured woodland species barely five inches in length. The Philippines are considered a sub-region of the Oriental region; but a part of the Archipelago, the Palawan group, belongs to the Malaysian sub-region. The birds of this group are treated in a separate appendix, and one of the most striking is the Palawan peacock pheasant, *Polyplectron emphanum*, which belongs to a genus not represented in the Philippines proper but ranging from Borneo to the Eastern Himalayas.

The authors have considered it necessary to suppress some well-known genera. They do not recognize the genus *Squatarola* and treat it as a synonym of *Pluvialis*, since they do not think the absence of the hind-toe in the grey plover is sufficient to place it in a separate genus from the golden plover. Had they studied Lowe's papers they would have learnt there are other differences which make a good case for keeping the two genera. It is unfortunate, too, that many well-established English names have been changed because the authors consider them unsuitable. Among others the common kingfisher becomes the river kingfisher, Swinhoe's snipe the marsh snipe, and the black-necked tailor-bird the common tailor-bird. All rather confusing for the amateur ornithologist who visits different parts of the East.

N. B. Kinnear

A RUSSIAN REVIEW OF BONDS IN CHEMISTRY

The Chemical Bond and the Structure of Molecules

(In Russian.) By Ya. K. Syrkin and M. E. Dyatkina. Pp. 588. (Moscow and Leningrad: State Scientific-Technical Publishing House of Chemical Literature, 1946.) 30 roubles.

The authors of this work, who in recent years have been making important contributions to the study of resonance, the diradical state, polarity in the hydrocarbon series, and the structure of the boron hydrides, are probably the best-known Russian workers in the field of quantum chemistry. The book is intended to fill the gap which has apparently existed in Russian chemical literature by reason of the absence of books comparable with the standard British and American treatises on the theory of the chemical bond and wave-mechanical conceptions of valency. It covers broadly the ground of Pauling's "Nature of the Chemical Bond", but in addition presents the mathematical foundations of quantum mechanics (Schrödinger's method), the detailed Heitler–London treatment of molecules, and the mathematical point of view in general; for the authors consider that the student can achieve the critical attitude essential for progress in this field only by becoming thoroughly acquainted with all the postulates, limitations and approximations involved in the deduction of the equations which he will use.

After a description of the principles of the electronic configurations of atoms, which includes an introduction to the conception of wave functions, there follows a wave-mechanical study of the hydrogen molecule ion, the hydrogen molecule, and the homopolar bond. The subjects of directed valency bonds, resonance, the method of molecular orbitals, infra-red and Raman spectra, dipole moments, bond energies, intermolecular forces, the crystalline state, complex compounds, and the structure of the boron hydrides are presented against a background of experimental data, and controversial matters are critically discussed. Quite recent work is reviewed; for example, Longuet-Higgins and Bell on B_2H_6 (*Proc. Roy. Soc.*, A, 183, 357; 1945).

The last three chapters (pp. 480–569) are entirely mathematical and deal with the three-electron problem (Slater's method), the calculation of resonance energy, and miscellaneous problems.

There are author, formulæ and subject indexes. The book appears to be more comprehensive and up to date than any single volume on the chemical bond at present available in the English language.

G. Stanley Smith

The Milky Way

By Bart J. Bok and Priscilla F. Bok. (Harvard Books on Astronomy.) Second edition. Pp. vi+224. (London: J. and A. Churchill, Ltd., 1946.) 18*s*.

WRITERS on astronomical subjects find it comparatively easy to give a popular or semi-popular description of such a parochial affair as the solar system, but not so easy to provide a similar description of the Galaxy. The book under notice is undoubtedly the best of the semi-popular type that has been produced on this subject, and it presents the reader with an excellent account of the methods used to explore the Milky Way and to fathom some of its secrets. Here we have descriptions of the means by which astronomers ascertain stellar distances, masses, sizes, temperatures, etc., and most of these can be easily understood by those who have little or no background in mathematics or physics. They will read the interesting story of our Galaxy—just one of millions—the longest axis of which is more than 100 million light-years, the number of stars probably exceeding 100,000 million. Some of these stars are so large that the sun could be placed at the centre, and the orbit of Mars would lie well inside their outer layers, while the whole system is moving around its centre, the speed of the sun being 150 miles a second and the time required to complete a revolution 200 million years.

It must not be assumed that all the secrets of the Milky Way have been laid bare; so much still remains to be done that it would be true to say that our knowledge of the Galaxy as well as of the extragalactic systems is very limited, and many years of patient research will be necessary before it is possible to settle a number of controversial points. Readers of this book will probably form the opinion that far more remains to be done than has yet been accomplished.

The work is illustrated with ninety-three figures, two of which are large-scale photographic maps of the Milky Way and thirty of celebrated astronomers whose investigations have been responsible for advancing our knowledge of the Galaxy.

M. DAVIDSON

Field Archæology

By R. J. C. Atkinson. Pp. x+238+8 plates. (London: Methuen and Co., Ltd., 1946.) 12*s*. 6*d*. net.

IT is all to the credit of British archæology that its technique of field-work and excavation should have been built far less from theoretical principles than from practical experience, won gradually in the field itself by the men and women on the job. But matters have latterly been coming to a point where the fruits of this experience required gathering together, for the benefit both of beginners and indeed of the men and women on the job themselves. Mr. Atkinson's book meets this requirement admirably. A little more than two hundred pages long and of convenient pocket size, it is exactly suited to the part of archæologist's 'companion', in which it should be assured of a long career of usefulness and many editions.

The author is still young, but he writes throughout from personal knowledge of what he is discussing, gained mainly in the region of Oxford, where he is now assistant keeper of antiquities in the Ashmolean Museum. True, workers in the regions of sterner physique in the north and the farther west may here and there have things to add; but the book abounds so richly in practical information and quietly shrewd advice that it is really indispensable for anyone pursuing out-of-door archæology, no matter where, nor whether professionally or as a constant or occasional hobby. Field-work and excavation, surveying, recording and photography, interpretation of evidence and the preparing of reports for publication are all treated thoroughly yet simply, and the plates and the author's diagrams are altogether excellent.

C. F. C. HAWKES

Plastics Applied

Being a Survey of Patent and Technical Literature with Collected Data of Interest to Users of Plastics in all Branches of Industry. Edited by Dr. V. E. Yarsley. Second edition. Pp. 528+lvi+8 plates. (London: National Trade Press, Ltd., 1946.) 42*s*. net.

THIS handsome volume represents the present stage in the development of plastics in so far as applications are concerned. Naturally, therefore, one would not expect to find a great deal relating to fundamental research. After an introductory review, a good account of the numerous uses of plastics in industry follows. Indeed the range is amazing: shipbuilding, photography, textiles, insulation, to mention but a few of the actual or potential uses. There are two chapters on welfare and safety problems, which will be welcome, and, at the end, a number of useful tables.

Two points of wide interest may be singled out; one is that with so much replacement to do in all branches of national life, the opportunity (and responsibility) for good design should be fully realized by manufacturers; the other stresses the manifold possibilities which occur in starting with substances almost universally colourless. The implication is that almost every conceivable hue should be within the grasp of designers and artists.

The compilers have managed to produce a book obviously suitable for consultation in the office and factory which is, at the same time, dignified and appropriate as a work of reference.

F. I. G. R.

A Bibliography of Statistical Quality Control

By Grant I. Butterbaugh. (Published for the Bureau of Business Research of the College of Economics and Business.) Pp. viii+114. (Seattle, Wash.: University of Washington Press, 1946.) 1.50 dollars.

STATISTICAL methods of controlling quality of output have now been tried out in many branches of industry, the War in particular having provided a strong impetus with its demand for large-scale fine-quality production. The literature of the subject has become bulky, and contains records of interesting ideas and extensive practical experience (together with, unfortunately, much wearisome repetition of the same first principles). This bibliography covers literature published up to 1945. Most of the entries are followed by a brief synopsis or a reference to published reviews. The compilation has been made carefully, and will be of service to many "statisticians, teachers, students and businessmen directly responsible for quality control". It is a pity that a subject index has not been included, but the book is not too large to be read completely by anyone searching for particular applications. The theory of quality control is developing rapidly, and it is to be hoped that up-to-date editions of the bibliography will be available at not too long intervals.

F. J. ANSCOMBE

THE EXPLORATION OF ANTARCTICA*

By Dr. BRIAN ROBERTS
Scott Polar Research Institute, Cambridge

THE sudden widespread interest in the Antarctic, aroused by the announcement that no less than twelve nations are organising expeditions to that region, has resulted in a spate of articles which has been chiefly remarkable for inaccurate rumours and speculations. Supposed rich deposits of uranium and other valuable minerals have been depicted as the prize for the winners of an international race to stake out territorial claims. It may therefore be useful at this stage to record the present position with regard to sovereignty and territorial claims, to summarize briefly what is known about Antarctic economic resources, and to add some notes about the various expeditions which are now either planned or in operation.

Sovereignty and Territorial Claims in the Antarctic

There are three areas of British territory in the Antarctic continent, administered by the Governments of the Colony of the Falkland Islands, New Zealand, and Australia, respectively. The Falkland Islands sector consists of the Falkland Islands Dependencies as defined by Letters Patent of July 21, 1908, and March 28, 1917. The New Zealand sector, known as the Ross Dependency, was defined by an Order in Council of July 30, 1923. The Australian sector, known as the Australian Antarctic Territory, was defined by an Order in Council of February 7, 1933.

Adélie Land, a French *enclave*, lies within the Australian Antarctic Territory. It was annexed by France by a decree of April 1, 1924.

Queen Maud Land came under Norwegian sovereignty by a decree of January 14, 1939.

The Pacific sector between the Falkland Islands Dependencies and the Ross Dependency has been partially claimed by the Chilean Government; but no Chilean expedition has ever visited this region. A Chilean decree of November 6, 1940, defined the sector between long. 53° W. and 90° W. as Chilean territory.

Since 1939 the Argentine Government has been pursuing an increasingly active policy to extend its earlier claim to the South Orkney Islands to the whole of the Falkland Islands Dependencies between long. 25° W. and 68° 34′ W. It will thus be noted that the Chilean and Argentine claims not only overlap with each other but also conflict with the British claim to the Falkland Islands Dependencies.

Finally, although United States citizens have laid claim to various regions in the Antarctic since Admiral Byrd's first expedition in 1928–30, the United States Government has never made any territorial claims in the Antarctic. So recently as December 27, 1946, Acting Secretary of State Dean Acheson repeated that his Government has not recognized any claims of any other nations in the Antarctic and has reserved all rights which it may have in those areas.

Economic Resources

Antarctic lands are barren, with little immediate prospect of any discoveries of minerals of commercial significance. Antarctic seas, however, support an extremely rich fauna, and for forty years the whaling industry has produced great profits. There is also a small but flourishing industry in seal oil. Apart from these, almost nothing is known about the economic resources of the region.

Low-grade coal or carbonaceous shales have been located in the Beacon Sandstone formation at Mt. Buckley, at the head of the Beardmore Glacier; at Granite Harbour in Victoria Land; in the Queen Maud Range; and at Horn Bluff in King George V Land. The reserves are probably large, but the samples examined are charred by volcanic action; and all the sites except Horn Bluff are far inland and inaccessible. Very small quantities of gold and silver have been found at Cape Denison in the Australian Antarctic Territory. Cassiterite (tin ore) has also been found in the Australian Antarctic Territory. Galena (lead ore) and pyrites (iron sulphide) have been found far inland in Marie Byrd Land in the Pacific Sector. Iron pyrites and copper ore have been found in the South Shetland Islands and Palmer Archipelago in the Falkland Islands Dependencies. All these occurrences have been insignificant. In short, nothing has yet been found of sufficient value to make exploitation worth while at such great distances from any market. It is scarcely necessary to add that no radioactive minerals or oil have been discovered in any part of the Antarctic. On the other hand, Antarctica is a continent of approximately six million square miles. Although most of this area is covered by an ice sheet, there are innumerable outcrops of accessible rock, and it would indeed be surprising if a sufficient search did not disclose mineral resources.

Expeditions

British. In 1943 the Colonial Office made arrangements to resume scientific and survey work in the Falkland Islands Dependencies. This programme, which was started during the War, has since been put on to a peace-time footing, and the organisation has been named the Falkland Islands Dependencies Survey. It is planned that this work in the land areas of the Dependencies will supplement the investigations carried out by the "Discovery" Committee and other British expeditions before the War.

In February 1944, parties, led by Lieut.-Commander J. W. S. Marr, R.N.V.R., were established at Port Lockroy in the Palmer Archipelago (Base A: ten men) and at Deception Island in the South Shetlands (Base B: four men). An attempt to establish a third base at Hope Bay in Trinity Peninsula was frustrated by adverse ice conditions. Two ships were employed: H.M.S. *William Scoresby* and *Fitzroy*. It was officially announced in the Press on April 24, 1944, that arrangements had been made to resume scientific and survey work in the Dependencies, and that fully equipped bases had been established. For security reasons, however, no information could be given during the War about the locality of the bases.

In the southern summer of 1944–45 three ships were employed: H.M.S. *William Scoresby*, *Fitzroy* and *Eagle*. A third base was established at Hope Bay (Base D) in February 1945, and four men were again left at each of the first two bases. A further hut was erected at Sandefjord Bay on Coronation Island in the South Orkneys. Commander Marr had to return to England owing to ill-health, and the command of the expedition was given to Captain A. Taylor, R.C.E. Dog teams and sledging equipment

---

* This article was accepted on January 22; it therefore takes no account of later developments.

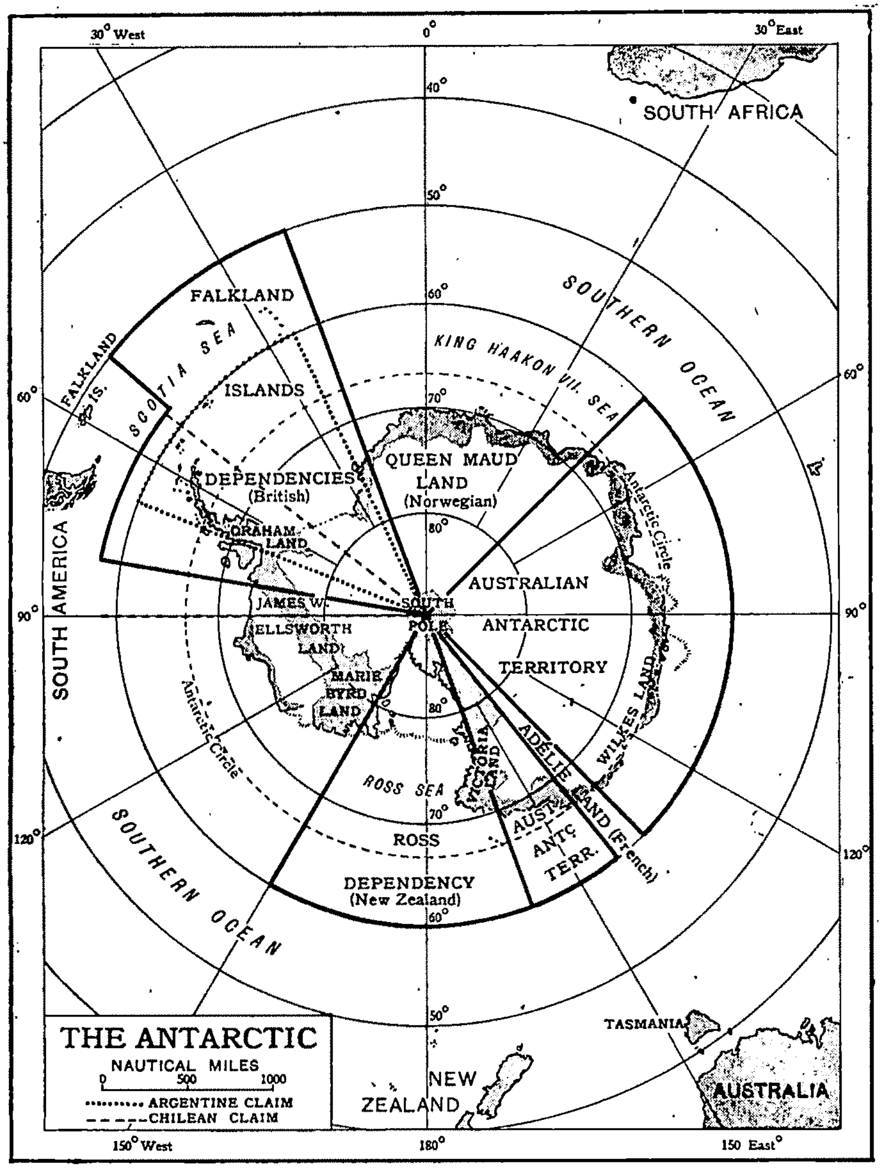

FIG. 1. THE ANTARCTIC SHOWING VARIOUS TERRITORIAL CLAIMS. SHADED AREAS HAVE BEEN ACTUALLY SEEN BY EXPLORERS

enabled the party at Hope Bay to sledge southwards during 1945, surveying James Ross Island and the mainland coast southwards to Cape Longing.

In December 1945 relief parties were sent out under the command of Surgeon-Commander E. W. Bingham, R.N. *Fitzroy* and H.M.S. *William Scoresby* were again employed, and a new ship, *Trepassey*, built in Newfoundland especially for ice work, made possible a more extended programme. Eight men were left at Hope Bay, and four each at Deception Island and Port Lockroy. New bases were established at Cape Geddes on Laurie Island in the South Orkneys (Base C: four men), and at Neny Fjord in south-west Graham Land (Base E: ten men). The old huts of the British Graham Land Expedition of 1934–37 at the Argentine Islands and Debenham Islands were repaired for the use of the Falkland Islands Dependencies Survey. A further supply of dogs and sledging equipment enabled the parties at the two mainland bases to carry out a series of survey journeys.

Meteorological stations are maintained at all these bases, and an investigation is being carried out into the possibilities of weather forecasting in the South Atlantic with particular reference to the development and movement of Antarctic depressions. Extensive geological and biological collections have been made, and the whole project has been planned with the view of making a systematic study of all aspects of the Falkland sector of the Antarctic. In December 1946 relief parties were again sent out from England in *Trepassey*, and it is this routine relief which has been incorrectly reported as a new British expedition.

A feature of the Falkland Islands Dependencies Survey has been that of Commonwealth and Empire co-operation with the United Kingdom. The staffs of the shore stations have included men from Australia, Canada, New Zealand, South Africa, Rhodesia and the Falkland Islands, while the crews of the *Eagle* and *Trepassey* came from Newfoundland. The Falkland Islands Dependencies Survey acts under the authority of the Governor of the Falkland Islands and the general direction of the Colonial Office with the co-operation of the Scott Polar Research Institute and the "Discovery" Committee.

No other activities originating in the United Kingdom are at present in progress in the Antarctic. The "Discovery" Committee's organisation and work in England are continuing, and it is possible that the Committee's ships will be re-commissioned.

United States. Two American expeditions will be working in the Antarctic this season, one sent out by the Navy Department under the command of Rear-Admiral R. E. Byrd and the other led by Lieut.-Commander Finn Ronne, backed by the American Geographical Society and other private organisations.

The Navy Department expedition was officially announced on November 12, 1946, and is the largest operation ever planned in the Antarctic. The objectives of the expedition are stated by the Navy Department to be (*a*) "training personnel and testing equipment in frigid zones", (*b*) "consolidating and developing the results of the U.S. Antarctic Service Expedition of 1939–41", (*c*) "developing naval techniques for establishing, supporting and using bases

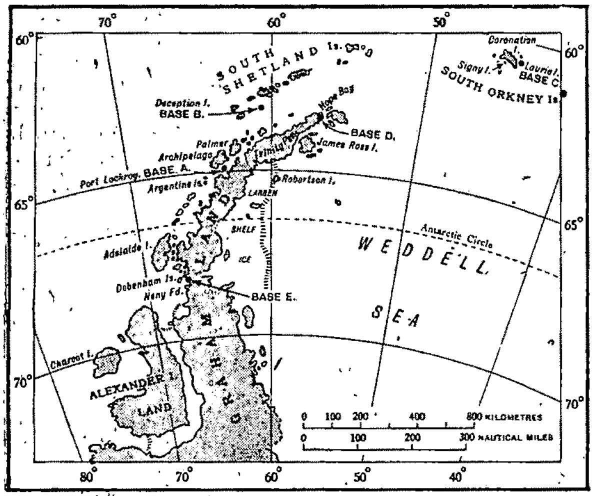

FIG. 2. BASES OF THE FALKLAND ISLANDS DEPENDENCIES SURVEY

under comparable conditions", and (*d*) "amplifying knowledge of the area with respect to hydrographic, geographic, geological, meteorological and electromagnetic propagation methods". For this purpose a task force of the Atlantic Fleet, augmented by units of the Pacific Fleet, has been assigned to the Antarctic during the navigable season of 1946–47. Technical control of the expedition is being exercised by Rear-Admiral Byrd, who is on duty in the Office of the Chief of Naval Operations as adviser on Arctic and Antarctic matters, and who is accompanying the task force. The commander is Rear-Admiral Richard Cruzen, who was Admiral Byrd's second-in-command in the 1939–41 expedition.

The task force has been divided into three main groups. The Central Group includes the flagship and headquarters communication ship, U.S.S. *Mount Olympus*, the Coast Guard icebreaker U.S.S. *Northwind*, Navy icebreaker U.S.S. *Burton Island*, the cargo ships U.S.S. *Yancy* and U.S.S. *Merrick*, and the submarine U.S.S. *Sennet*. The East Group is under the immediate command of Captain George J. D. Dufek. It includes the seaplane tender U.S.S. *Pine Island*, the oiler U.S.S. *Canisteo*, and the destroyer U.S.S. *Brownson*. The West Group is under the immediate command of Captain Charles A. Bond. It includes the seaplane tender U.S.S. *Currituck*, the oiler U.S.S. *Cacapon*, and the destroyer U.S.S. *Henderson*.

It is not intended that any of these ships should remain in the Antarctic during the southern winter, but a shore base capable of supporting a small party for at least eighteen months will be established, possibly on the site of Admiral Byrd's former base at 'Little America' on the Ross Shelf Ice, "to provide against contingencies". Aircraft for shore-based flight operations will be flown in from an aircraft carrier after this base has been set up. Each of the two large seaplane tenders carries three camera-equipped Martin Mariner patrol seaplanes, a small scout plane and two helicopters. Each of the two icebreakers carries one scout seaplane and one helicopter. Long-range operational and mapping flights are to be made by the Mariners, while the scouts will be used mainly for short-range ice reconnaissance and the helicopters for rescue work in case of forced landings.

While the purposes of the operation are described as primarily of a military nature (that is, to train naval personnel and to test ships, aircraft and equipment under polar conditions), the expedition will afford an unequalled opportunity to collect scientific information. To take full advantage of this, arrangements have been made for a number of scientific workers to participate under the general guidance of the Director of Naval Research, Rear-Admiral P. F. Lee. The Weather Bureau, Coast and Geodetic Survey, Coast Guard, the U.S. Geological Service, the Hydrographic Office, the material bureaux of the Navy Department and other Government scientific agencies have provided meteorologists, geographers, oceanographers, hydrographers, photographers, etc. The Army will be represented by air and ground force observers and by quartermasters interested in clothing and rations. The Marine Corps has furnished a part of the air flight crews and other cold-weather specialists. Altogether, approximately 4,000 officers and men are taking part in this gigantic expedition.

Thirteen vessels of the task force sailed from United States ports on December 2, 1946. It was announced that the eastern group would go to Peter I Island and would work eastwards round the continent. The western group would head for a point south-west of New Zealand and follow the coast of Antarctica westwards. The central group would head for the Ross Sea.

Commander Finn Ronne plans to visit the west coast of Graham Land and has announced his intention of establishing a base in Marguerite Bay, where his party of twenty men would spend the winter. The Diesel-powered wooden ship *City of Beaumont*, formerly known as *Navy ATA—215*, has been lent to the expedition by a special Act of Congress and should reach the Antarctic by mid-February. The expedition is equipped with three aircraft. Commander Ronne plans to re-occupy the old "East Base" huts of the American Antarctic Service Expedition of 1939–41, which are on the same small island as the southern base of the Falkland Islands Dependencies Survey. The situation which may arise from two independent and unco-ordinated expeditions based within 200 yards of each other will not be without difficulties.

Argentina. In November 1946 the Argentine Government made known its intention to establish "a permanent meteorological observatory" to complement the one it has for long maintained in the South Orkney Islands. On December 20 the Argentine Press announced that the naval transport *Patagonia* would shortly be sailing for the Antarctic. The vessel sailed from Buenos Aires on January 4 and will be assisted by three other ships—the transport *Chaco*, the oil tanker *Ministro Ezcurra*, and a whale-catcher. The expedition, which is equipped with an amphibian aircraft, is carrying a relief party for the existing Argentine meteorological station at Scotia Bay on Laurie Island in the South Orkneys. It is stated that the expedition "intends to explore the Antarctic sector of Argentina", as far as 74° S. (that is, the west coast of Graham Land), returning home at the end of March. It was confirmed that the expedition is also to establish a new Antarctic meteorological station and to "reaffirm Argentina's claim to sovereignty over the entire zone lying between the Argentine mainland and the South Pole". An Argentine wireless news bulletin of January 3 stated that a Chilean naval officer would accompany the expedition, reciprocating the gesture of the Chilean Government in including Argentine officers in its expedition.

Chile. On December 14, 1946, the Chilean Foreign Office announced that preparations were being completed to send the frigate *Iquique* and the transport *Angamos* of the Chilean Navy to Antarctica "to establish contact with that most remote corner of the national territory and to determine on the spot all of the possibilities it offers to the country". This statement confirmed that two Argentine naval officers would go with the Chilean expedition to "the American sector of Antarctica" (that is, the sector facing the tip of South America), and concluded that the Government was "taking the greatest interest in the distant Antarctic zone, considering that it forms a prolongation of the soil of the motherland and that it contains important resources for the national economy". Later unconfirmed reports from Chile state that this expedition consists of three ships which will all return to Chile in March 1947.

Australia. Sir Douglas Mawson has for long been advocating the establishment of a permanent research station on the Antarctic coast south of Australia. In 1939 the *Wyatt Earp* was purchased by the Commonwealth Government with the view of transporting scientific parties to the Australian Antarctic Territory. The War necessitated postponement of these plans, and it has not yet been possible to recondition the *Wyatt Earp* after her war-time coastal patrol work. On December 20, 1946, it was announced that the Australian Cabinet had decided to send a naval vessel, equipped with a suitable aircraft, on a short reconnaissance voyage to the Antarctic this season to locate a suitable site for a base to be occupied next year. It was also stated that the Commonwealth Government would proceed immediately with plans for the exploration of the Australian Antarctic Territory. A later announcement, however, indicates that this reconnaissance expedition will not take place this season.

New Zealand. On December 28, 1946, Mr. Peter Fraser made a statement about the official New Zealand attitude. The New Zealand Government, he said, had no desire to send any expedition to the Antarctic ahead of that led by Admiral Byrd for the purpose of asserting sovereign rights in the Ross Dependency. It had been hoped for some time to extend scientific work in the Antarctic, but the War had made this impossible. A departmental committee was investigating the practicability of establishing a permanent scientific station in the Ross Dependency, and the dispatch of an expedition next year would be considered when the examination was completed. New Zealand hoped to co-operate with the United Kingdom and Australia in an international plan of Antarctic research: details of which were still under discussion. The Americans were welcome to fly over New Zealand territory.

South Africa. In 1944 a South African Antarctic Research Committee was formed on the initiative of the Geological Society of South Africa at Johannesburg. This Committee has for more than two years been actively considering the possibility of a South African Antarctic expedition and has been in close touch with those in the United Kingdom who are interested in similar projects. The suggestion has been put forward that a South African expedition should establish a base in Coats Land. General Smuts has advised the Committee that the South African Government would not be likely to support the project unless other nations showed interest in a joint scheme. The Committee continues its investigations, and, as a start, has accepted an offer to send a South African geologist to join the staff of the Falkland Islands Dependencies Survey.

International Expedition. Plans for a British–Norwegian–Swedish expedition to the western part of Queen Maud Land are being discussed. The area to be investigated was photographed from the air by the Germans in 1938–39 and was named by them Neu-Schwabenland. The German maps and photographs reveal a remarkable area of ice-free land which offers a field for research of the first scientific importance. British participation in this expedition is being discussed by a joint Committee of the Royal Geographical Society and the Scott Polar Research Institute. It is proposed that this expedition shall be purely scientific, and it is unlikely to start before 1948 or 1949.

Whaling expeditions. The Antarctic whaling season opened on December 8, 1946, and extends to April 7 next. In view of the present world food shortage, the results will be awaited with more than usual interest. Whale oil is used in the margarine and lard compound industry and for making soap; important by-products are fertilizers and animal feeding stuffs.

The 1945–46 whaling season was disappointing, due mainly to bad weather and the unpreparedness of the principal fleets. The total oil production was only 820,883 barrels, compared with 2,820,771 barrels in 1938–39. This season fifteen floating factories with their fleets of catchers have sailed for the Antarctic, comprising seven from Norway, three from the United Kingdom, one from South Africa, one from the Netherlands, one from the U.S.S.R., and two from Japan—the last despite protests from other participants owing to that country's failure in the past to observe the restrictions imposed by the International Whaling Convention. This is the first occasion upon which the Netherlands and the U.S.S.R. have undertaken whaling in the Antarctic. Apart from the three land stations at South Georgia, all these whaling expeditions will be operating at sea, mainly outside territorial waters.

The post-war regulation of whaling was considered at an international whaling conference held in Washington last November. The short-term need for oil and the long-term need to preserve the stock of whales are difficult to reconcile; but it is generally agreed that the stock must be protected by a total limit to the Antarctic catch. Although the total catch must be shared by a number of nations, it is not expected that this will be a source of international dispute at the present time.

The news of all these expeditions has failed to evoke the expressions of pleasure and interest from foreign countries which formerly accompanied such enterprises. The Russian Press has charged the United States with prospecting for uranium in order to increase their stock of atomic bombs. The Argentine and Chilean Press have complained that the British and American expeditions are equivalent to a trespass on their national territories. American, British and Dominion newspapers speculate on the race for uranium and other minerals, and emphasize the political rivalry which is accompanying the partition of the last continent.

It is a sad reflexion on current political psychology that such claims and charges should invade a field which was once characterized by international courtesy and goodwill. What is now happening is the realization on the part of all concerned that the economic development of this frozen continent is technically within sight—providing there is anything there which is worth the trouble of development. The political question which is now beginning to arise—well in advance of any economic necessity—is by whom, and in what way, development is to be undertaken. There is room enough and to spare in Antarctica to absorb all the energy and enterprise which can be devoted to it. The greater part of the continent is still unexplored, and there are countless unsolved problems awaiting investigation. This task of exploration is essentially one that demands international co-operation. While official interest is now undoubtedly solving the greatest difficulty of earlier explorers, namely finance, the hurried preparations for most of the present expeditions can only result in much wasted effort. Moreover, friction is almost unavoidable when two or more expeditions plan, without prior consultation, to operate in the same area.

The Colonial Office has made it clear that it will always welcome foreign co-operation in the exploration of the British territories in the Antarctic which are administered by the Falkland Islands Government. It is impossible, however, to arrange co-operation between expeditions which keep their plans secret until they sail. In Great Britain provision exists for international co-ordination in the Scott Polar Research Institute and the Royal Geographical Society, which have recently set up a joint Antarctic Research Committee. Mention has already been made of the similar Committee which has for some time been in existence in South Africa. When the British Empire Scientific Conference met at Cambridge in June 1946, useful preliminary discussions about Antarctic exploration and research took place at the Polar Institute. The foundations have been laid for maintaining closer contacts and for training Dominion research workers in polar techniques in the Falkland Islands Dependencies. It is to be hoped that this co-operation will be developed to the fullest possible extent.

THE MISSION OF THE UNIVERSITIES

By J. MACKAY-MURE

RECENT events have resulted in strong pressure on the universities to increase the number of students. The Barlow Committee, in recommending that the present output of university scientific workers should be doubled "at the earliest possible moment", expressed the hope that there might be a similar increase in the number of arts students. The Clapham Committee urged a large increase in the provision made by the universities for teaching and research in the social sciences. It is, however, extremely doubtful whether the existing universities are in a position to double their output of students within the next ten years without surrendering their essential character and independence. As the universities expand they will have to recognize that the great bulk of their funds, both for purposes of income and of capital expenditure, can only come from the Government, and there is a growing nervousness lest the Government, which is now paying the piper to the tune of £9,000,000 a year, will soon want to call the tune.

While it is undoubtedly true that the universities are facing an organisational crisis, brought about by the pressure of new demands for trained personnel, this is less than the whole truth. They are also facing a crisis about themselves and their function in society. Because the genuine freedom of a university is created from within and can only be destroyed from within, academic freedom is, or ought to be, more than a tradition of the universities. The necessity for it has, unhappily, tended to be obscured in recent years by the importance which has been attached to the teaching function of a university. If too much emphasis has been placed on this and other activities which it is right and proper that a university should, in certain circumstances, pursue, too little attention has been paid to those which it has a bounden duty to pursue at all times and under all conditions. The modern doctrine that the primary function of a university is to supply experts in the spheres of science, business, administration, and the social sciences can become both dangerous and heretical—not because it advocates any single thing which ought not to be done, but because it represents an idea of a university which is out of focus. It thrusts into the background that conception of it as a centre of cultural life and cultural progress which makes freedom not merely desirable but a first essential. Without freedom such a centre ceases to be a university, a community of scholars within which every man may open his mind to a total engagement in the struggle for truth.

The maintenance of this freedom has to-day acquired a new significance. As the State system of education is reformed and developed, there is the assurance of that technical and vocational training on which the efficiency of the community depends. But the quality of the community depends primarily on its standards and its ideals, on the defence and promotion of fundamental values in life and progress. Although standards and values are by no means the monopoly of those who are brought into association with the life of a university, it is doubtful whether they can be maintained if the true idea of a university is allowed to decay. "It is not," says Plato, "the life of knowledge, not even if it includes all the sciences, that creates happiness and well-being, but a single branch of knowledge—the science of good and evil." Science, economics, and sociology provide the frame of contemporary society and satisfy its material needs, but "unless we have the knowledge of good and evil, their use and excellence will be found to have failed us".

Since nothing would be more disastrous than that the immensity of this issue should be made an excuse for pursuing a policy of *laisser-faire*, the decision of the General Council of the Student Christian Movement to call together a commission of senior members of the universities to help it "to consider the fundamental pre-suppositions of university education and their implications for the work of the S.C.M. in the post-war university" must be widely welcomed. As a result of the discussions of the commission, which met in 1944 and 1945, certain points of broad agreement emerged "in respect of (*a*) a criticism of the philosophy underlying modern university education; (*b*) the Christian reasons for supporting and defending with vigour a 'free' or 'liberal' university; (*c*) the essential beliefs necessary to maintain such a university; (*d*) the responsibilities of a Christian student in such a university". In order to get the matters with which the commission was concerned more widely discussed, the S.C.M. has now issued a series of twelve University Pamphlets[1] on different aspects of the problem.

By no one has the problem been more clearly stated than by Ortega y Gasset when he declared that the universities are "living below the demands of their time". "There is," to quote from his lively and stimulating "Mission of the University"[2], "no denying the fact that man invariably lives according to some definite ideas which constitute the very foundation of his way of life. . . . We are passing at present, despite certain appearances and presumptions, through an age of terrific *un-culture*. Never perhaps has the ordinary man been so far below his times and what they demand of him. Never has the civilized world so abounded in falsified, cheated lives. . . . Hence the historic importance of restoring to the university its cardinal function of 'enlightenment', the task of imparting the full culture of the time and revealing to mankind, with clarity and truthfulness, that gigantic world of to-day in which the life of the individual must be articulated, if it is to be authentic."

Accepting this diagnosis in "The Mind of the Modern University", Prof. John Baillie concludes that the present crisis can be traced to the failure of the universities to remain "closely integrated communities, inspired by a common purpose and cemented by certain common and firmly held convictions". This has led at the universities to a "refusal of definite commitments" and "the cultivation of a continued suspense of judgment". Although no man and no institution can live without a working basis of belief, Prof. Baillie naturally rejects the idea of coercing students to adopt any single philosophy of life. At the same time, he insists that it is a primary duty of a university to confront its members with the importance of possessing a clearly defined philosophy of life. Failure to do this is, he maintains, "an abnegation of the very purpose for which a university exists".

The magnitude and difficulties of this task are frankly faced by Prof. H. A. Hodges[3]. What is not, he says, sufficiently understood is that knowledge is a source of power. The universities are trafficking in a commodity the acquisition of which means power, and are caught in the same contradiction between professed aims and real desires as affects the whole of society. "The world has," he continues, "never been fuller of high hopes and high principles than in the last hundred years. The hopes have not been realized and the principles have been ineffective. Why ? Because there is a contradiction between the principles we profess and the desires by which we are actually moved. Our ideals, in which our conscious selves sincerely believe, are full of justice, humanity and peace. . . . But our imaginations, as reflected in art and literature, in popular amusements, and in our actual behaviour, are full of something else. Our admiration and emotional attachment go to power, and to knowledge as a source of power." Believing that this conflict between professed principles and effective archetypes is common to all contemporary social and political movements, Prof. Hodges finds no difference in this respect between liberal democracy of the Atlantic type and authoritarian communism on the Russian model.

Since this belief is held, in greater or lesser degree, by all the authors in this series, it is not surprising to find them also agreed in insisting that members of a university have, in Miss D. M. Emmet's phrase[4], a responsibility to focus "the intellectual conscience of the community". Nevertheless, she is emphatic that the first responsibility of a university, not only for its own sake but also for the sake of the community, is to *be* a university. "It should," she continues, "be a place where the criticism and evaluation of ideas is continually being carried forward ; where 'nonsense' can be exposed for what it is ; and where the 'intellectual virtues' of sincerity of mind are being fostered and transmitted."

Few, if any, will dispute Miss Emmet's conclusion that, within a totalitarian or purely utilitarian society, the university can only lose its soul or fight for it ; but neither she nor any of the other authors in the series is able to offer a positive solution of the immediate problem. The American expedient, recommended in the report of the Harvard Committee, is to provide students with 'integrating courses' designed to give a conspectus of knowledge or an introduction to some of the major issues of our time. But who are to be the integrators ? And are such courses, however good, more than an admission of the magnitude of the problem ? The sum total of human knowledge far exceeds the power of the human mind to contain it. The old unity of knowledge, or the belief that such a thing as truth about the whole system of things exists and can be found by human minds, is gone. But, however curricula may be devised and courses integrated, it is still possible for universities to be places in which real battles rage ; and, as long as the battles are concerned with fundamental issues and the combatants are fired with a determination to find a clearly defined philosophy, the universities will retain their cardinal function of 'enlightenment'.

ASTROLOGY AND ASTRONOMY IN THE SEVENTEENTH CENTURY

By JOSHUA C. GREGORY

ASTROLOGY was an integral part of astronomy and science from Ptolemy onwards. Many astrologers lived before A.D. 170, when Ptolemy flourished at Alexandria ; but he conveniently dates the beginning of an astrological fervour by giving the science a philosophy. Kepler dates the finish of the astrological vogue much less sharply, for the horoscopes only melted slowly out of seventeenth-century science. There were, of course, dissents during the long astrological grip on the best minds : they were active in the beginning and they were gathering towards the end. Astrology, however, as the history of science from Ptolemy to Kepler shows, is one firmly established and finally discarded hypothesis of science.

This is clear in Lynn Thorndike's six volumes, "A History of Magic and Experimental Science" (1923–41). Thorndike includes astrology under magic. Whether this is right or wrong, his exhaustive and valuable survey includes the astrological data. He begins with the first century A.D. and ends with the sixteenth. His history of this period, his occasional extensions into the seventeenth century, and many supplemental data, disclose astrology as an integral part of astronomy from Ptolemy to Kepler.

A modern astronomer who took fees for casting horoscopes would be legitimately suspected of deceiving victims who pay because they are deceived. A paragraph on the "Fourth Centenary of the Birth of Tycho Brahe", in *Nature*, Nov. 23, p. 740, suggests that earlier astronomers of those days earned a living by palming off horoscopes on the credulous; this ignores the persisting grip of astrological beliefs when Tycho Brahe and Kepler lived.

The Copernican system had an astrological part at first, though the movements of the earth, rather than the stellar motions, influenced destiny. When the "De Revolutionibus" was published on behalf of Copernicus in 1543, it was stripped of this astrology. Osiander's editing tried to soften any papal opposition to the new astronomy (Thorndike, l.c., 1941, **5**, 413f.). If the astrology was stripped off to assist the softening, an astrological astronomy deferred, in this instance, to possible papal protests against horoscopes.

Tycho Brahe does not surprise the historical sense by vindicating astrology, or by compiling annual predictions for the Court at Copenhagen, or by casting horoscopes for the royal family. Astrology was still rife when he died in 1601. Sir Francis Bacon accuses astrology of many errors; but he also exhorts science to reconstruct it justly.

Astrology is losing its grip in "The Anatomy of Melancholy" (1621), but has not yet lost it. Robert Burton seems to admit in one place that the stars are the most remote causes of "Heroical Love". In another he does not try to decide between astrological physicians and their opponents. He exclaims against the vanity of "genethliacal studies", but he notes that Saturn was lord of his geniture, that he had Jupiter in his sixth house, and that Mars had a hand in the matter. The stars do incline: Burton retains this astrological faith. They incline too gently, however, to compel those whom reason rules: he softens down the astrological power to decree or enforce. Christian astrology had frequently refused to place man's freedom at the mercy of the stars or planets. A prolonged powerful grip is perceptible in Burton's many references to astrological lore; his attempt to believe in astrology without believing too much suggests a loosening of the grip.

Sir Thomas Browne, in "Religio Medici" (1643), seems, somewhat ambivalently, to believe and disbelieve. No laborious argument against astrology is needed, for any truth it may have does not injure divinity. If astrology has any truth, Sir Thomas notes, he may "outlive a Jubilee". He does not "revolve Ephemerides and Almanacks in expectation of malignant aspects, fatal Conjunctions and Eclipses", but he does suspect a piece of the "Leaden Planet" in himself since he was born "in the Planetary hour of Saturn". In the "Pseudodoxia Epidemica" (1646), he does not condemn astrology as a popular error when he warns men against the pretentious astrologer who abuses the "worthy enquiry" of the stars. Satan also deceives men, Browne thinks, by "conceits of stars and meteors" other than "their allowable actions". In "Christian Morals", published in 1716 after his death, Sir Thomas commends the "celestial aspects" for admonition and advertisement, though they should not determine men's ways.

Bacon restricts "celestial operations" to "masses of things" and excludes the "calculation of nativities" from rational astrology. Burton and Browne obviously knew their own nativity horoscopes, and many others thought it at least prudent to know theirs. The degree of belief in the accuracy of the casting or in the horoscope when cast probably varied; but, as Browne hints, the horoscope might contain wholesome warnings. Any astrologer could conscientiously cast horoscopes under such conditions. The horoscope, precautionary or more trusted, did not necessarily involve an insistence on fatal necessity in the stars. The more prudent astrologers, Bacon admits, had always denied such fatal necessity.

The astrology which had prevailed widely among the intellectual élite since Ptolemy persisted pertinaciously. A Kepler who checks his own horoscope on the events of his own life, and, as Singer says, keeps in effect an "astrological diary", is historically quite intelligible. He is equally intelligibly an honest caster of horoscopes for the many who still believed in them—wholeheartedly or with varying qualifications.

OBITUARIES

Dr. F. F. Blackman, F.R.S.

FREDERICK FROST BLACKMAN was born on July 25, 1866, and died on January 30, 1947. His was a full life, which resulted in valuable contributions to botany, and to his University and College, of which he was a member for nearly sixty years.

His first published contributions to botany were two papers in the *Philosophical Transactions of the Royal Society* in 1895. They began a series entitled "Experimental Researches on Vegetable Assimilation and Respiration"; of which the twenty-first paper appeared in 1933. Only a few of the series bear Blackman's name, but all reveal the impress of his mind. They are a record of some of the investigations carried out by him and by the students working under his leadership. In all these researches he played an important part not only during the experimental work but also in marshalling the results for publication. In 1928 a new series commenced with three papers entitled "Analytic Studies in Plant Respiration". Other papers for this series have for some time been in a state which those with a less exacting standard than Blackman's would consider ripe for publication. These two series record the main field of his scientific activities. The views and discoveries he has already recorded have been so incorporated into the body of biological knowledge that their epoch-making character may be forgotten. It is a commonplace to elementary students that most of the gaseous exchange between leaves and the atmosphere takes place through stomata; but although this was suggested so long ago as 1832, it was much disputed until convincing experimental evidence was provided by Blackman in 1895. Whatever may be decided concerning the degree of generality of his Theory of Limiting Factors there is no doubt that the paper on "Optima and Limiting Factors", which he published in 1905, provided an outstanding clarification of biological thought and has had far-reaching effects. He was the last person to think that he had achieved finality in his formulations; as he liked to express it, he was making a first approximation to the truth, and he hoped it would pave the way for a closer approach. He was a pioneer in the application of precise quantitative methods in plant physiology and in the application of physico-chemical laws to the interpretation of biological processes. Yet he never failed to realize the complexities of the organisation of biological systems, and he retained his interest in these problems to the end.

Blackman's other major contribution to botany was the effect he had on those who had the privilege of listening to his lectures and on those who had the even greater privilege of doing research under his guidance. His lectures were masterly presentations of experimental results marshalled in such a way as to illuminate his theme. Much of the material was drawn from investigations made under his guidance, while that garnered from biological literature often appeared in a completely new form after having been subjected to his analytical mind. To experience to the full the discipline of his ways it was necessary to work on a problem under his guidance; his was a precise mind which gently indicated the right path. To see one's presentation of the results of an investigation analysed and then synthesized into a new form was indeed an education. He performed this service for many others who sought his advice.

Blackman was a member of the staff of the Cambridge Botany School from his appointment as demonstrator in 1891 until his retirement from the readership in botany in 1936, and as such he undertook a full share of the administrative work of the department. This, together with his wise advice, which continued after his retirement, contributed largely to its smooth running. He was a perfect colleague, and he had the gift of inspiring all, both staff and assistants, to give of their best. When the time came for the extension of the Botany School in 1933, he devoted as much thought to the planning of the new facilities as he had done to the running of the old department. He not only formulated his own requirements down to the smallest detail but also stimulated others to proceed in the same way.

When, in recognition of the active school which had developed under Blackman's inspiration, a Sub-Department of Plant Physiology was created in 1931 with the aid of a benefaction from the Rockefeller Fund, he naturally took charge, and but for complications of age and date of retirement he would have become the first professor of plant physiology in Cambridge. On relinquishing the readership his old students and associates presented him with his portrait, painted by Henry Lamb, which now hangs in the Botany School.

Elected a fellow of the Royal Society in 1906, he was awarded a Royal Medal in 1921, and gave the Croonian Lecture in 1923. He was president of the Botany Section of the British Association in 1908 and president of the Section of Plant Physiology at the International Botanical Congress held in Cambridge in 1930.

He devoted much time and thought to the affairs of St. John's College, of which he was steward for several years and in which he lived as a bachelor fellow until 1917. His advice on a wide range of subjects, including the preservation of old buildings, the erection of new ones, pictures, plate and many others, was sought and respected.

In 1917 he married Elsie Chick. They planned and built a house and surrounded it with a garden which gave them and their friends great pleasure, and provided opportunities for the exercise of his artistic and botanical interests. Mrs. Blackman and their son survive him.

Blackman had the same approach to all problems. He collected the facts and considered them carefully and dispassionately before giving his opinion. It was done so thoroughly and unobtrusively that there was a temptation not to notice the care that he had bestowed. He was as gentle as he was wise. To those who knew him well Blackman was a great man.

G. E. Briggs
F. T. Brooks

J. W. Sandström

Johan Wilhelm Sandström, meteorologist and oceanographer, who died in January 1947, was born on June 6, 1874. He was chief of the Meteorological Division of the Meteorological and Hydrological Institute of Sweden during 1919–39.

After leaving school, Sandström began life in a factory, but he came under the notice of I. Bendixson, professor of mathematics in the University of Stockholm. Bendixson managed to arrange that Sandström should have time off to go to lectures at the University. He took a keen interest in the promising young man, and the development of Sandström's mathematical talent was largely due to Bendixson's influence.

In 1898 Sandström became a pupil of V. Bjerknes, and his first substantial contribution to meteorology was a paper in the *Meteorologische Zeitschrift* (April 1902) on the "Relation between Temperature and Wind in the Atmosphere under Stationary Conditions", in which he applied to this problem a development by Bjerknes of Kelvin's classical paper of 1869 on vortex motion. Sandström arrived at the conclusion that in Europe, cyclones usually have a cold centre and anticyclones a warm centre, and he indicated the significance of the 'thermal wind', though he did not give it that name, which came nearly sixteen years later. He noted also, what has recently been rediscovered, that North American cyclones are in a much earlier stage of development than European cyclones.

Sandström next collaborated with Helland-Hansen in computing exhaustive tables for the application of Bjerknes' circulation theory to the currents of the ocean. He was also joint author with V. Bjerknes of the first volume of "Dynamic Meteorology and Hydrology", published by the Carnegie Institution of Washington in 1910—the first instalment of a treatise designed to present in an ordered and rational form the principles and development of meteorology and hydrography from the point of view of a mathematical physicist. The treatise was completed by the publication in 1932 of the magnificent three volumes on "Physical Hydrodynamics with applications to Dynamical Meteorology", in which V. Bjerknes had the assistance of J. Bjerknes, T. Bergeron and H. Solberg. But Sandström's help and encouragement had been outstanding and were fully recognized by V. Bjerknes, who acknowledged in the preface that without it he would scarcely have ventured on this great work.

Later in life, Sandström was occupied almost entirely with investigation into the Gulf Stream and its influence on climate. He was not content to use only theory and the observations of others: he made expeditions to test for himself the application of his theory. He prepared a very complete memoir embodying the results of his work. A part of this memoir is being printed by the Swedish Academy of Science and was in the press at the time of his death.

Sandström was a big, genial man. One of his colleagues describes him as a man "with a very vivid and vital interest in Nature and in the problems suggested by natural phenomena. His theoretical ability, which was combined with a good amount of common sense, was so much more remarkable as he was largely a self-educated man, having risen from the position of an aid in a mechanical factory to being the assistant and collaborator of scientists like Svante Arrhenius, Otto Pettersson and Vilhelm Bjerknes."

Meteorologists in England who knew Sandström either personally or through his writings will join with their colleagues in Sweden in mourning the loss of a great pioneer. E. GOLD

WE regret to announce the following deaths:

Prof. Louis Cobbet, formerly professor of pathology in the University of Sheffield, on March 10, aged eighty-five.

Major M. W. K. Connolly, an authority on the land mollusca of Africa, on February 26.

Prof. Llewelyn G. Owen, formerly professor of mathematics in the University of Rangoon, on February 23.

Mr. H. A. S. Wortley, principal of University College, Nottingham, on February 21, aged sixty-one.

NEWS and VIEWS

A Giant Sunspot

A GIANT sunspot group, one of the largest on record, crossed the sun's disk between March 3 and 17, with central meridian passage on March 10·2. Excepting one or two days, the prevailing cloudy skies gave little opportunity for detailed observations, but the following facts may be given. The maximum area of the group, consisting mainly of a pair of great spots, was 4,300 millionths of the sun's visible hemisphere. This exceptionally large area is less than that of the February 1946 spot (4,900 millionths) but greater than that of the July 1946 spot (3,950 millionths). The average area during disk passage of the present spot may, however, be less than that of the July spot (3,750) and is certainly less than that of the February spot (4,400 millionths). Two geomagnetic disturbances, not of great intensity, occurred while the present spot crossed the disk, namely, March 8–9 and March 15–16. Their provisional ranges at Abinger kindly communicated by the Astronomer Royal were

	D	H	V
1st storm	60′	270γ	220γ
2nd storm	30	150	120

The latitude of the spot group was 22° south, but the tilt of the sun's equator at this epoch of the year brought the group to within 15° of the centre of the disk at central meridian passage. Yet no great magnetic storm occurred about one day after central meridian passage, for which statistical results suggested a high probability. It is significant, however, that radio fade-out data, at any rate in Greenwich daylight hours, indicated that no intense solar flare (like those of February 6 and July 25, 1946) occurred when the spot was within the central half of the sun's surface turned towards the earth. Practically on the same solar meridian as the recent spot was another naked-eye group in latitude 13° north, and with maximum area about 1,400 millionths.

Effect of the Moon on Radio Wave Propagation

FROM time to time, some observational evidence has been forthcoming suggesting that the strength of signals received from radio transmitting stations over fixed paths is under certain conditions dependent upon the position of the moon at the time of observation. In particular, H. T. Stetson has investigated this matter, and in 1944 (*Terr. Mag. and Atmos. Elec.*, **49**, 9) described the results of the analysis of some eight years measurements taken at Boston on the strength of signals received from the Chicago broadcasting station. Contrary to his expectations, the evidence strongly indicated that the strength of the signals was dependent upon the age of the moon, although the effect was of a complex nature. It will also be recalled that in a paper published in 1939 (*Proc. Roy. Soc.*, A, **171**, 171), E. V. Appleton and K. Weekes showed the existence of a lunar tide effect in the height of Region E of the ionosphere. The tide was found to be semi-diurnal, with an amplitude variation of about ± 1 km. If these results are interpreted according to the simple theory of the formation of the ionized regions, they indicate a relative air-pressure oscillation several thousand times the measured relative pressure oscillation at ground level.

In a recent communication to the Editors, Mr. P. A. de G. Howell, 77 Glandovey Road, Fendalton, Christchurch, N.W., New Zealand, claims to have observed during 1938–39 and 1944–45, a correlation between the variation in long-distance transmission conditions at short wave-lengths and the phases of the moon. It was observed that there was a minimum of background noise and high signal strength with little tendency to fade for about two or three days on either side of full phase, these conditions changing to a maximum of noise with poor signals and fading around the time of new moon. The cycle of occurrences is easily confused with those associated with the solar period of similar duration, with which, however, it moves in and out of phase as the months progress. While both Dr. Stetson and Mr. Howell suggest that the effects are the result of changes in ionization in the earth's upper atmosphere, it is clear that the whole subject requires further investigation before definite conclusions can be reached as to the cause of the effect.

Population Trends and the World's Resources

DR. C. L. BERTRAM has presented in a minimum compass the main known facts of the relationship of population and human needs to the availability of animal and vegetable raw materials and foodstuffs (*Geogr. J.*, **107**, Nos. 5 and 6, May–June 1946). He accepts Carr-Saunders' estimates that the world's population has increased fourfold in the last three hundred years—from 545 million in 1650 to 2,057 million in 1933. Only Africa (100 million to 145 million) has failed to take part in this remarkable increase. Although probably three quarters of the world's people are farmers or their dependants, the majority of these do not get sufficient food to maintain health. Seventy-five per cent of Asia's 1,150 million people have a diet far below the standard for health: even the best-nourished countries, such as

Britain and the United States, had 20–30 per cent of the people suffering from malnutritional diseases before the War. The near-famine conditions now faced by the world are nothing new, but shortages are affecting those who, by their advantageous economic position, had previously been virtually immune from even the fear of famine.

Britain imports the largest quantity of food of any country in the world—in some cases as much in normal times as two thirds of the total of a given commodity entering into the world trade. If exporters are no longer compelled by economic needs to sell the food they badly need themselves, then the position is indeed difficult for the importers. The world position has been aggravated by that greatest scourge ever known to man—soil erosion—and the irrational over-exploitation of forests, fisheries and grasslands. The plea is made for policies based on real knowledge and quantitative data rather than half-knowledge or guess-work.

'Wellcome' Photographic Year Book

THE well-known 'Wellcome' Exposure Calculator, Handbook and Diary, published by Burroughs Wellcome and Co., has appeared in a modified form as the 'Wellcome' Photographic Year Book. The contents are similar, and those who made use of the original publication before the War will remember that it consists essentially of a diary, a number of pages ruled for recording the essentials of photographic exposures, a fund of useful photographic information, and a very useful exposure calculator. Used in conjunction with the illustrated examples of different types of subject, the calculator is one of the best of its kind. On the back of the exposure calculator, also in disk form, is a depth of field calculator with which the depth of field can be obtained for lenses of various apertures and focal lengths. The keen photographer will find the Year Book a valuable asset for the pocket.

Frank B. Jewett Fellowships: Awards

THE American Telephone and Telegraph Company, which founded the Frank B. Jewett fellowships for research in the physical sciences three years ago to commemorate the retirement of its eminent vice-president in charge of development and research, has announced seven awards for 1947–48. The purpose of the fellowships is to stimulate and assist research in the fundamental physical sciences, and particularly to provide the holders with opportunities for individual growth and development as creative scientific workers. The awards carry an annual stipend of 3,000 dollars to the holder and 1,500 dollars to the institution at which the recipient elects to do research. The awards are designedly post-doctorate, and only those who have recently received their doctorates or who are about to receive them are normally considered.

The awards for 1947–48 have been made to: (1) Dr. Martin G. Ettlinger (University of Texas and Harvard University), at present investigating the chemistry of cyclopropene and dicyclobutane derivatives at the California Institute of Technology as a Jewett Fellow for 1946–47; he intends to continue his present research studies. (2) Wallace D. Hayes (California Institute of Technology), who proposes to investigate problems of transonic and supersonic fluid flow. (3) Paul Olum (Harvard and Princeton Universities); he is to carry out research in algebraic topology. (4) Aadne Ore (University of Oslo), at present an F. E. Loomis Fellow at Yale University; he will work on the theory of combinations of electrons and positrons. (5) Dr. Alfred Schild (University of Toronto and the Carnegie Institute of Technology); he will study relativistic field theories in quantum mechanics. (6) Dr. Robert L. Scott (Harvard and Princeton Universities), at present Jewett Fellow, engaged in research in chemistry at the University of California; he is to continue his studies of the thermodynamics of solutions. (7) Edwin H. Spanier (Universities of Minnesota and Michigan), at present a Rackham Predoctoral Fellow at the University of Michigan; he will engage in research in the homotopy classification of continuous mappings.

British Iron and Steel Research Association: Appointments

MR. R. H. MYERS has been appointed head of the Steel Making Division of the British Iron and Steel Research Association and Dr. A. H. Leckie has been appointed deputy head. Mr. Myers studied under Profs. J. O. Arnold and A. MacWilliam at Sheffield, and, after a post-graduate course of one year, started his industrial career with the Midland Iron Company. Since 1930 he has been associated with research in the steel industry, as open-hearth officer to the Iron and Steel Industrial Research Council, in addition playing an active part in the Corrosion and Heterogeneity Committees set up jointly by the Research Council and the Iron and Steel Institute.

Dr. A. H. Leckie studied chemistry at University College, London, under Profs. F. G. Donnan and C. K. Ingold. After graduating, he was engaged in research for several years on molecular spectroscopy. In 1937 he joined the Technical Department of the British Iron and Steel Federation and was engaged on research on iron and steel works plant and principally on open-hearth furnaces. Dr. Leckie joined the British Iron and Steel Research Association, when that body took over the work of the Federation's Technical Department, and is in general charge of research work on furnace design and operation.

Radiocommunication Convention

THE Institution of Electrical Engineers is holding a Radiocommunication Convention during March 25–28, at which some seventy papers will be presented dealing particularly with war-time activities in this field and their resulting application to future peace-time development. The Convention will be opened on March 25 by Sir Stafford Cripps, President of the Board of Trade, after which Sir Stanley Angwin will give a lecture on "Telecommunications in War". On March 26 four meetings will be held dealing in turn with long-distance point-to-point communication, naval, military and aeronautical communication, and the special features of pulse modulation in communication systems. The subject of short distance communication will be dealt with during the following morning, while the afternoon and evening sessions of March 27 will be devoted to direction-finding and war-time broadcasting respectively. On the morning of March 28, Sir Edward Appleton will open the session on propagation with a paper entitled "The Investigation and Forecasting of Ionospheric Conditions". The afternoon of the same day will be devoted to radio components, and in the evening, Sir Clifford Paterson will conclude with a review of the Convention and the future trends of development indicated by the papers and discussions. At an additional meeting to be held on April 2, a number of papers will be presented dealing with the various types of continuous wave radio navigational aids which have been developed during recent years.

Summer School in X-Ray Crystallography

In recent years the study of materials by means of X-ray diffraction has come to occupy an important place in scientific research both in the universities and in industry. This field of study enters into physical, chemical, metallurgical, mineralogical and biological research. The necessary X-ray technique is, however, highly specialized, and for its proper understanding a fundamental training is required. An attempt to meet the demand for such courses was made at the University of Cambridge by the provision of Summer Schools in the years 1943–46. Although these schools were very successful, they are now to be discontinued; but, if the demand warrants, consideration will be given to their continuation at the Manchester College of Technology under the direction of Dr. H. Lipson. Correspondence should be addressed to the Director of Extra-Mural Studies, University, Manchester, 13.

Cambridge Summer School in Physical Chemistry

A Summer School on "Some Recent Advances in Physical Chemistry" will be held in the University Department of Physical Chemistry, Cambridge, during August 16–23 inclusive. A course of eighteen lectures will be given by the staff of the Department on the following topics: (1) molecular structure and valency theory (6 lectures); (2) chain reactions (6 lectures); (3) physics and chemistry of rubbing solids (6 lectures). Practical work on these topics will be arranged for those who desire it. Demonstrations will also be given and full opportunity provided for discussion with the lecturers and with those carrying out research in the laboratory. An inaugural lecture will be given on the evening of Saturday, August 16, and the course will finish on the evening of August 23. Arrangements have been made for most of those attending the School to be accommodated in colleges. Applications to attend the School must be received by May 1. Inquiries should be addressed to the Joint Secretaries, Summer School in Physical Chemistry, University Department of Physical Chemistry, Free School Lane, Cambridge.

Pasteur Exhibition

A Pasteur Exhibition will be held at the Science Museum, South Kensington, London, during April 10–May 26. The exhibition has been arranged and provided, with the assistance of the Cultural Relations Department of the French Foreign Office, by the Palais de la Découverte in Paris, where it has recently been on show. This institution is devoted to the exposition of modern science, employing for the purpose the most advanced techniques of visual education. The Pasteur Exhibition includes a chronological account of the chemical and biological work of Louis Pasteur on fermentation, putrefaction, the spontaneous generation of life, and on the causative organisms of numerous diseases of men, animals and plants. The results of his work are illustrated by panels dealing with pasteurization in the brewing and other industries, and the raising of disease-free silkworms. A section of the exhibition deals with the Pasteur Institutes established throughout the world for the preparation of serums and vaccines for the combating of disease epidemics.

Fourth International Cancer Research Congress

The Fourth International Cancer Research Congress will be held in St. Louis, Missouri, U.S.A., during September 2–7, 1947. The Union Internationale contre le Cancer having accepted the invitation of the American Association for Cancer Research, the Congress will be held under the joint auspices of these two organisations, with Dr. E. V. Cowdry, professor of anatomy, Washington University School of Medicine, and director of research of the Barnard Free Skin and Cancer Hospital, as president of the Congress. Of the three Congresses that have been held previously, the first was in Madrid, in 1933; the second in Brussels, in 1936; the third in Atlantic City, New Jersey, U.S.A., in 1939. The State Department in Washington having approved of the International Cancer Research Congress, official invitations will shortly be sent to foreign governments. Dr. M. G. Seelig, Barnard Free Skin and Cancer Hospital, St. Louis 3, Mo., is chairman of the Publicity Committee of the Congress.

An Optical-Acoustic Method of Gas Analysis

Mr. A. Whitaker, chief engineer of Ascot Gas Water Heaters, Ltd., Research Laboratories, Tolworth, Surrey, writes: "The instrument described by Dr. F. I. Callisen in *Nature* of February 1, p. 167, is being used in these laboratories. It is based on the description published by Dr. Luft-Oppau and has been further developed at our request by the Infra-Red Development Co., Ltd. A working model will be shown by Ascot Gas Water Heaters, Ltd., at the forthcoming Physical Society's Exhibition."

Announcements

Prof. W. J. de Haas, professor of experimental physics and meteorology in the University of Leyden, and Sir John Russell, formerly director of Rothamsted Experimental Station, Harpenden, Herts, have been elected foreign associates of the Paris Academy of Sciences.

The Committee of Privy Council for the Organisation and Development of Agricultural Research has appointed Mr. James Turner, president of the National Farmers' Union, to be a member of the Agricultural Research Council.

Mr. J. F. Foster, formerly registrar of the University of Melbourne and secretary of the Australian Vice-Chancellors' Committee, has been appointed secretary of the Universities Bureau of the British Empire, on the retirement of Mr. W. B. Brander from that office. Mr. Brander, who has been secretary since 1930, will continue for a while in an advisory capacity.

Mr. N. F. Astbury has been appointed director of research to the Guest, Keen and Nettlefolds group of companies. Mr. Astbury was director of the Research Laboratories of Joseph Sankey and Sons, Ltd., one of the member firms of this group. It is intended that these laboratories shall now become the headquarters of the research organisation of the combine.

The Research Council of Alberta is offering two fellowships, each of value 1,320 dollars for one year, tenable at the Council's laboratories, University of Alberta, open to graduates in chemistry and chemical engineering. Applications should be sent by air-mail to the secretary of the Council, University of Alberta, as soon as possible.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Phenolic Substances Concerned in Hardening the Insect Cuticle

THE hardening of the protein of insect cuticles is due to the tanning action of an agent produced by oxidation of a phenolic substance[1]. The hardening of the cockroach ootheca (*Blatta orientalis*) is analogous to this process, and we have recently demonstrated that the phenolic substance responsible in this case is 3 : 4-dihydroxybenzoic acid (I) (protocatechuic acid)[2]. Not only was this acid isolated in substantial quantity from the oothecæ, but also it was found that an aqueous solution of synthetic protocatechuic acid in presence of oxygen produced the characteristic darkening effect of the secretion of the right colleterial gland of the female cockroach upon the protein secretion of the left gland. This study of the cockroach ootheca represented the initial phase of a more extensive investigation of the hardening process in insects ; as a next step it was decided to attempt the isolation of phenolic substances from other species, to find out whether protocatechuic acid is a general hardening agent or whether the agent varies from species to species. The investigation is far from complete but, particularly in view of the general interest in the problem of the insect cuticle and the recent publications of Dennell[3] and Fraenkel and Rudall[4], it is felt that the results so far obtained are worthy of record at this stage. The species examined were *Calliphora erythrocephala*, *Lucilia cæsar* (puparia) and *Tenebrio molitor* (adults), and the experimental procedure and results can be summarized as follows.

Calliphora erythrocephala. A stock of mature larvæ which had ceased to feed were kept at room temperature ; they were examined daily, and any puparia (whether darkened or not) were picked out and stored in water containing a little cyanide and sulphur dioxide. When about 100 c.c. of puparia had been collected, they were crushed and extracted with acidulated aqueous alcohol (20 per cent) until the extract showed no ferric reaction. The aqueous alcoholic extract was concentrated *in vacuo* and then extracted continuously with peroxide-free ether. The ethereal solution so obtained was treated with diazomethane, evaporated, ester groups hydrolysed with methanolic potassium hydroxide, and the final product recrystallized from water and sublimed at 100°/10^{-1} mm. The acid isolated in this way had m.p. 178° and was identified as 3 : 4-dimethoxybenzoic acid (veratric acid) by direct comparison (m.p. and mixed m.p.) with an authentic specimen.

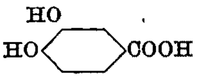
Tenebrio molitor. A stock culture was examined once a week and freshly emerged adults picked out and stored as above. When enough had been collected, the whole bodies were crushed and treated in the same way as the blowfly puparia. Two batches, collected from the same stock one after the other, were used ; the first contained about 2,000 and the second about 750 individuals.

(1) The product from the first batch, after hydrolysis of ester groups, was unexpectedly soluble in water but separated from benzene/light petroleum as colourless crystals, m.p. 94–96°. After several recrystallizations from the same solvent mixture a homogeneous substance was obtained, m.p. 104–105° (20 mgm.) (found : C, 58·0 ; H, 5·9. $C_{11}H_{14}O_5$ requires C, 58·4 ; H, 6·2 per cent). From the analytical results it seemed likely that this acid was the hitherto undescribed α-hydroxy-β(3 : 4-dimethoxyphenyl)-propionic acid (3 : 4-dimethoxyphenyl-lactic acid). Accordingly, 3 : 4-dimethoxypyruvic acid[5] was subjected to catalytic hydrogenation; *dl*-α-hydroxy-β-(3 : 4-dimethoxyphenyl)-propionic acid so obtained (found : C, 58·3 ; H, 6·0. $C_{11}H_{14}O_5$ requires C, 58·4 ; H, 6·2 per cent) had m.p. 104°, undepressed in admixture with the acid isolated from *Tenebrio molitor*.

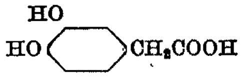
(2) The purified product (9·8 mgm.) from the second batch had m.p. 95–96°, undepressed in admixture with 3 : 4-dimethoxyphenylacetic acid (m.p. 95–96°)[6], but depressed by 3 : 4-dimethoxyphenyl-lactic acid. Further confirmation of its identity was provided by nitration ; the recrystallized nitro-compound formed needles, m.p. 209°, undepressed by 6-nitro-3 : 4-dimethoxyphenylacetic acid (m.p. 208°) synthesized by the method of Oliviero[7].

Lucilia cæsar. Extraction of *Lucilia* puparia (*c.* 500 c.c. collected as for *Calliphora*) with acidulated aqueous alcohol gave no material with a positive ferric reaction, and on working up the extract in the manner described above, the only crystalline product obtained was succinic acid (50 mgm.), identified by analysis, chemical properties, m.p. and mixed m.p. Extraction of the crushed larvæ with ether also failed to yield any phenolic material ; the unsaponifiable fraction of the ethereal extract contained, as crystalline constituents, a hydrocarbon (80 mgm.), m.p. 60–61° (found : C, 85·3 ; H, 14·9 per cent) and cholesterol (200 mgm.), identified by m.p., mixed m.p. and preparation of its acetate.

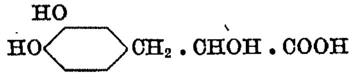
In the experiments above described, the phenolic acids present in the insect material were methylated with diazomethane in order to simplify working up, so that the products actually isolated were the corresponding methyl ethers. It is, however, clear that *Calliphora* puparia contain protocatechuic acid (I) and *Tenebrio* imagines 3 : 4-dihydroxyphenylacetic acid (II) and 3 : 4-dihydroxyphenyl-lactic acid (III). The presence of (II) in the elytra of the latter species has already been reported[8].



(I)



(II)



(III)

It would seem likely from the isolation of only 3 : 4-dimethoxyphenylacetic acid in one experiment with *Tenebrio* and of 3 : 4-dimethoxyphenyl-lactic acid in the other that, had larger amounts been available, both compounds would have been isolated in each case. Further work is required to settle this point and to establish whether any protocatechuic acid is present in the same insect. Fraenkel and Rudall[4] have shown that the substance responsible for the darkening of the blood after death is probably free tyrosine ; the first product of the action of polyphenol oxidase on tyrosine is probably dihydroxyphenylalanine, and it is interesting that the three phenolic acids so far detected by us represent a complete series of what would be the expected stable degradation products of the latter. It is, of course, clear that the preliminary experiments here reported do not provide any answer to the obvious question whether, in *Tenebrio*, (II) or (III) themselves take part in the hardening process, or whether they are intermediate products in the conversion of 3 : 4-dihydroxyphenylalanine to protocatechuic acid, which then acts as hardening agent.

On the mechanism of the hardening process itself, we have as yet made only a few preliminary studies, and our results will be communicated at a later stage. It would, however, seem likely that it is brought about by the condensation of the oxidized *o*-dihydroxy acid with protein chains to form stable cross-linked structures in which the nitrogen originally present in free amino-groups becomes directly attached to the aromatic nuclei. Such a reaction, which would give structures resistant to the attack of hydrolytic agents, has its analogy in the well-known condensations of quinones with amines, and in particular that of *p*-benzoquinone with glycine[9]. This hypothesis appears to be in harmony with all the known facts about the hardening process.

The failure to detect any phenolic acid in the *Lucilia* larvæ examined is rather striking and requires further study. It may, however, be bound up with the fact that darkening of the puparium in *Lucilia* is slower, and the final colour paler, than in *Calliphora* or *Sarcophaga*, so that the hardening agent may only be present in very small quantity at any one time. The function of the considerable amount of succinic acid isolated is obscure, but it is probably derived from the larval blood, since it has also been isolated from the blood of *Gastrophilus* larvæ[10].

Permeability of Insect Cuticle

I have chanced to make an observation, at present unexplained, which may throw light on the properties of insect cuticle.

The leg of the cockroach (*Periplaneta americana*) is somewhat transparent, and it is easy to observe the main trachea through the cuticle. If one puts a drop of water on the exterior of the leg, just over this trachea, minute droplets appear almost instantaneously inside the trachea. In all cases the droplets appear only in that length of the trachea which is covered by the outer drop. These droplets later coalesce, and if the water drop on the outside of the leg is allowed to evaporate they eventually disappear.

The droplets do not wet the intima of the cuticle, and are judged to consist mainly of water. They appear in both the amputated and living leg; if, however, the trachea is collapsed by mechanical pressure, etc., this phenomenon does not occur.

Similar droplets were also observed with certain other liquids (acetic acid, benzene, ether, etc.), but they disappeared more quickly than in the case of water. Droplets, however, did not appear with glycerine.

The droplets which appear in the trachea might be due to cooling and condensation of water following evaporation of the drop on the surface or to some osmotic effect, if one could postulate penetration of liquid through the cuticle. Direct chilling of the leg failed to produce this phenomenon, but if a drop of water is placed on a chilled leg, droplets still appear in the trachea. In the latter case temperature is gradually rising, so there is no question of further chilling. Moreover, arguing on theoretical grounds, the amount of water appearing in about 1 mm. length of trachea is much more than can be accounted for even assuming that the air inside the trachea is 100 per cent saturated and all the water vapour condenses. To test the second possibility, distilled water, a series of salt solutions (from 0·7 to 1·5 per cent) and cockroach blood were tried. In each case the droplets appeared. It is evident, therefore, that the droplets are not due to physical or chemical differences between external liquid and tissue fluids.

The cuticle of *Rhodnius* is sufficiently transparent, and it is easy to observe the main trachea through the cuticle in the abdominal segments on the dorsal side. Droplets can be produced in it by applying water externally.

Structures of Ethylene Oxide and *Cyclo*propane

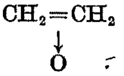
The recent communication of Walsh[1] includes several statements which are open to question. The suggestion that the reactions of ethylene oxide are at present considered to be due to instability caused by ring-strain is not acceptable without qualification and explanation. Nobody, one hopes, still retains any purely mechanical idea of strain such as one finds in the springs of models. Nowadays reactions are universally attributed to the functions of electrons and nuclei, and an interpretation of the special reactivity of such a series as acetylene, ethylene, *cyclo*propane and *cyclo*pentane can surely be found by the application of quantum mechanical principles to the usual formulæ. These represent nothing more than the mode of linking of the atoms in the molecule, combined with an indication of the degree of symmetry of the statistical distribution of electrons. Thus we may be confident that the ring-binding in *cyclo*propane has the symmetry of an equilateral triangle, that in ethylene oxide of an isosceles triangle, and that of propylene oxide of a scalene triangle. The usual formula for *cyclo*propane is therefore as satisfactory a symbol as can be devised.

The statement that trimethylene oxide is less stable than ethylene oxide is surely incorrect. Is this a case of the old confusion between stability (or reactivity) and ease of formation ?

Again, the reactions of ethylene oxide are not to be compared with those of ethylene as stated by Walsh; they are, however, very similar to those of acetaldehyde. Under ordinary conditions of temperature and pressure, the olefines are anionoid in the first phases of reactions, whereas the aldehydes and ketones, and also the olefine oxides, are cationoid. That is, a reaction of ethylene is normally initiated by electron donation; a reaction of ethylene oxide by electron acceptance. The case of reaction with acids is exceptional in that a proton is probably first taken up by the non-bonded oxygen electrons, and in the resulting complex the oxygen–carbon link possesses enhanced cationoid character.

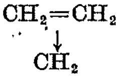
The claim that the conception of electron donation by bonding electrons is novel can be admitted only if it is limited to such new structures as those now proposed for ethylene oxide and *cyclo*propane. As a stage in reaction mechanism the idea can be traced back to Kekulé, whose theory of the formation of additive complexes and their redistribution can only be translated in modern terms by the use of reactive bonding electrons. If it were otherwise, saturated compounds could undergo no chemical transformations. Although it is true that a proton can often be regarded as a point of entry into the molecule, yet it is not difficult to find cases where the activity of a covalent link, carbon to carbon, should be assumed. For example, in 1916 I postulated[2] the conjugation of the unsaturation of *cyclo*propane and *cyclo*butane rings with an ethenoid group, and gave as an example of conjugated addition to such a system the formation of pinene hydrochloride, which occurs with intramolecular rearrangement.

As a written symbolic expression, the formula (I) for ethylene oxide appears to be quite unsatisfactory. As pointed out by Walsh, (I) shows an analogy with the amine oxides, but the behaviour of ethylene oxide does not support the implications. There is, no doubt, a small dipole moment, but not that expected of a molecule containing $\rightarrow O^-$. The amine-oxides are easily reduced to amines; ethylene oxide is not reduced to ethylene but rather to ethanol, and that with no great ease. The very natural extension to the azoxy compounds would be incorrect. These substances cannot be formulated as (III); they have been proved to be (IV).



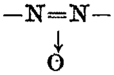
$\begin{array}{c}\mathrm{CH_2{=}CH_2}\\ \downarrow\\ \mathrm{O}\end{array}$

(I)



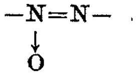
$\begin{array}{c}\mathrm{CH_2{=}CH_2}\\ \downarrow\\ \mathrm{CH_2}\end{array}$

(II)



$\begin{array}{c}\mathrm{-N{=}N-}\\ \downarrow\\ \mathrm{O}\end{array}$

(III)



$\begin{array}{c}\mathrm{-N{=}N-}\\ \downarrow\\ \mathrm{O}\end{array}$

(IV)

The formula (II) for *cyclo*propane is still less satisfactory. It does not express the symmetry of the molecule, and an attempt to achieve this by writing two other formulæ alongside would be nothing more than an admission of that degree of symmetry and in effect a reversion to the accepted structure.

What we need here is not new formulæ to set down on paper, but an explanation on quantum mechanical principles of the degree and quality of reactivity exhibited by assemblages of nuclei and electrons having the overall or average symmetry and spatial arrangement indicated by the usual structures and models. The overlapping of the orbitals would appear to supply this without the necessity for writing new constitutional formulæ.

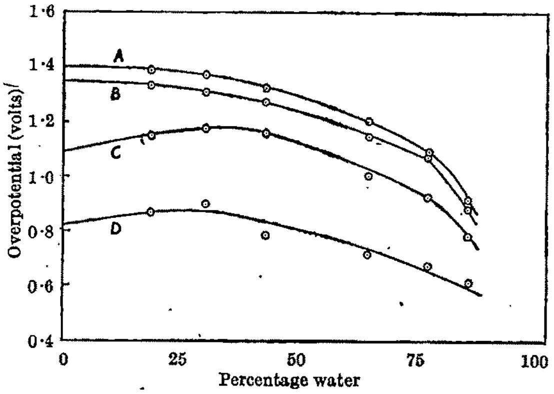
Effect of the Solvent on Oxygen Overpotential

RECENT work on the effect of the solvent on the hydrogen overpotential[1] has proved a fruitful source of evidence on the relative probability of the various suggested slow stages in the reactions at the cathode during the electrolytic evolution of hydrogen. No corresponding evidence seems to be recorded for the solvent effect on the oxygen overpotential, concerning which the following is a preliminary report. Few media are available for such experiments owing to anodic oxidation: aqueous acetic acid and aqueous dioxane were chosen for their suitable properties in this respect.



Curve *A*: 10^{-1} amp./sq. cm.; *B*, 5×10^{-2} amp./sq. cm.; *C*, 10^{-2} amp./sq. cm.; *D*, 10^{-3} amp./sq. cm.

Measurements have been carried out on smooth platinum anodes in a series of aqueous – non-aqueous mixtures containing these solvents, over a current density range of 10^{-3}–10^{-1} amp. sq. cm. The effects of both non-aqueous components are similar. The overpotential increases at first rapidly and then with decreasing slope upon increase of non-aqueous content (see graph). The Tafel equation ($\eta = a + b \log I$, where η is overpotential, I is current density, and a and b are constants) is approximately applicable in all systems; the values of b are all greater than in water. The increase in overpotential with time of polarization and the 'long-time' decay of overpotential after cessation of the polarizing current are not essentially affected by the solvent.

These results are not in accord with the slow discharge theory of Erdy-Gruz and Volmer[2], according to which possible solvent effects would be expected to depend primarily upon changes in the solvation energy of the OH^- ion; it seems very probable that this remains approximately constant in the systems examined[3]. From Eyring, Glasstone and Laidler's prototropic transfer theory[4], it seems logical to argue that presence of the non-aqueous component would serve to break up the continuous structure of solvent molecules bound to the anode and thus facilitate transfer of hydrogen atoms from the electrode to the solution layer. The overpotential would, therefore, be expected to be lower in aqueous – non-aqueous than in aqueous media, which is the reverse result to that found. Interpretation of the present experiments follows clearly from the assumption of the retardation of the heterogeneous combination of oxygen atoms caused by the presence of the non-aqueous component attached to the anode. It is assumed that both solvent components are adsorbed, but that, owing to steric factors, acetic acid and dioxane molecules exert a greater poisoning effect on the reaction velocity than water.

A fuller account of this work will be published elsewhere.

Spread Around the Initiating Point of the Detonation Wave in High Explosives

There is an old belief that the detonation wave in an explosive must travel a certain distance from the initiating point before attaining its final speed. In order to elucidate this problem, cylindrical charges of pressed T.N.T. have been fired with the detonator in different orientations and at various distances from the end surface of the charge. During experiments the flame was photographed on a film running with a constant speed of about 100 m./sec. Between the charge and the camera a screen with a vertical slit, 5 mm. wide, was fitted 1 m. from the charge. In all cases the axis of the charge was horizontal and pointed at the camera.

The charges with the dimensions 99·8 mm. × 99·8 mm. were initiated by electric detonators No. 8 from Imperial Chemical Industries Ltd. The priming charge consisted of a lead azide–lead styphnate mixture (0·22 gm.), and the base charge, 18 mm. long, of tetryl (0·688 gm.). The diameter of the detonator was 6·8 mm. and of the hole in the charge 7·2 mm. The centre of the free end surface of the detonator was placed at various distances, denoted *d*, from the photographed end surface of the charge. The axis of the detonator coincided in

Case 1 with the axis ; depth of the hole for detonator : 99·8-*d* mm.
Case 2 with a horizontal radius } depth of hole :
Case 3 with a vertical radius } 62 mm.

A typical photographic record is reproduced in Fig. 1. The time axis is a horizontal line assumed to lie at equal distances from the points of the two protruding horns, which mark the arrival of the detonation wave at the upper and lower intersections between a vertical line through the initiating point and the cylindrical surface of the charge. A relative displacement in the time direction of the horns indicates a vertical excentricity of the initiating point. Zero time is the point where a line through the points of the two horns intersects the time axis.

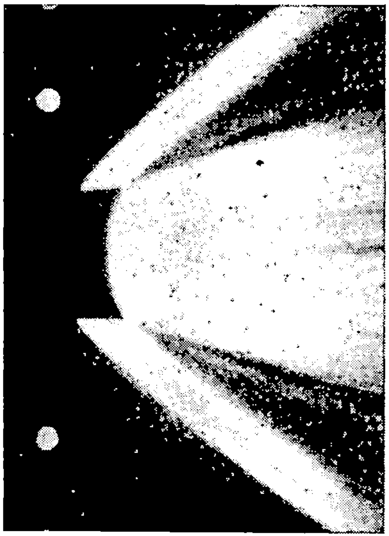

Fig. 1. Typical photographic record. Case 1, $d = 59{\cdot}5$ mm.

The curved front between the horns shows how the detonation wave successively reaches the end of the charge. A vertical tangent to this front marks on the time axis the travel time to the end surface after deducting the travel time to the cylindrical surface.

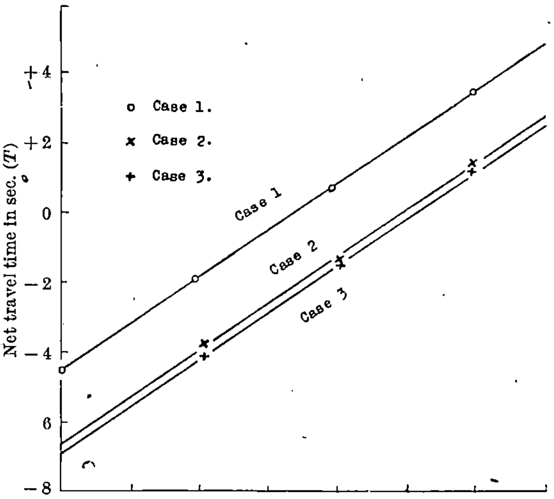

Fig. 2

The relation between this net travel time, *T*, and the distance, *d*, in the three cases is as shown in Fig. 2. In all cases the curves are straight lines with the same slope. Hence it may be concluded that the detonation is propagated with a uniform speed in all directions from the detonator.

For any distance *d* the difference between the travel times in Case 1 and Case 2 is about 2·1 μsec., which with due consideration of the detonation velocity of tetryl places the initiating point about 18 mm. from the free end of the detonator or almost exactly on the contact surface between the priming and the base charge. The small time difference (0·2 μsec.) between the lines of Case 2 and Case 3 may probably be explained by the fact that the depth of the hole for the detonator should have been 68 mm. instead of 62 mm. to get the initiating point exactly on the axis of the charge.

The slope of the lines corresponds to a wave-speed of 7,470 m./sec., which is 10 per cent higher than the generally accepted value 6,800 m./sec. for T.N.T. The discrepancy probably lies in the loss of speed when using built-up charges, as may be usual in routine tests. This question will be more thoroughly discussed elsewhere.

The camera was constructed and built by the Försvarets Forsknings Anstalt (FOA 2), who kindly placed the camera and some of their experts at our disposal.

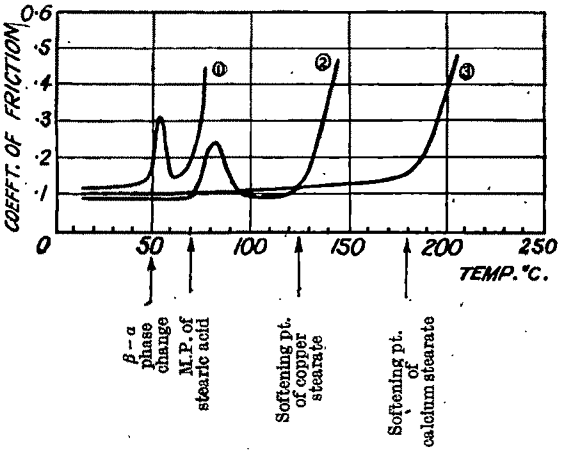
Lubricating Properties of Molecular Layers of Stearic Acid and Calcium Stearate on Metal Surfaces

FOLLOWING the work of Bowden, Gregory and Tabor[1], we have made friction-temperature measurements on mono- and multi-layers of calcium stearate and stearic acid on various metals. These authors stated that for each metal the transition from smooth to stick-slip sliding and a rise in the friction occurred at the melting or softening point of a surface film of metal soap produced by reaction with the fatty acid. It seemed, therefore, that in mixed films of soap and acid there should be fluctuations in the friction curve corresponding to the melting points of the substances present.

We deposited molecular layers of calcium stearate and stearic acid on copper, platinum and stainless steel by the Langmuir – Blodgett method[2] from a 10^{-4} molar solution of calcium carbonate. At *p*H 6 these layers contain 60 per cent soap and 40 per cent acid[3]. We used the Bowden – Leben friction apparatus to study the frictional behaviour.



(1) Platinum; (2) Copper; (3) Stainless steel

The temperatures at which changes in friction occurred corresponded closely to known physical changes of the layer substance in bulk (see graph and table).

Metal	No. of monolayers	Transition temperature (° C.)	Remarks
Platinum	1	No lubrication	
	3	,, ,,	β to α transformation at 54° C. M.P. stearic acid, 69° C.
	5	20–25 50–60	
	7	40–45 70	
	9	45–55 75–85	
Stainless steel	1	150–160	Softening point calcium stearate, 180°
	3	170	
	4	170–190	
Copper	1	No lubrication	
	3	70 125	M.P. stearic acid, 69°. Softening point copper stearate, 125°
	7	70 125	
	9	70 125	
	21	70 125	

With copper surfaces there are two fluctuations. The first, at the melting point of stearic acid, is not permanent and is thought to be due to the melting of the stearic acid, which, when liquid, is able to react with the surface, forming solid copper stearate. The friction then falls to its original low value and continues so until the softening point of copper stearate (125° C.), above which temperature a permanent increase in friction occurs.

On stainless steel no frictional changes occur at the melting points of stearic acid or ferric stearate (100–125° C.), but there is a transition at the softening point of calcium stearate (180° C.). With platinum, a fluctuation occurs below the melting point of stearic acid. Similar fluctuations are observed with palmitic and octacosanoic acids on platinum at 45° C. and 80° C. respectively. These temperatures are very closely similar to the temperatures at which β, α phase changes were observed in X-ray studies of monolayers of these acids on gold surfaces by Dupré la Tour[4]. It appears that the friction change is related to this phase transformation. There is also, as with copper, a sharp rise in friction at the melting points of the acids; but since no reaction can take place, no subsequent recovery occurs.

In general, each fluctuation corresponds to a softening or melting point of one of the constituents of the lubricating layer; but the frictional effects, and the number of layers required for lubrication, depend considerably on the nature of the underlying metal. Calcium stearate does not appear to lubricate copper and platinum, since with a mixed film, final breakdown of lubrication occurs at the same temperature as when pure stearic acid is spread on the surfaces[5]. Yet calcium stearate appears to lubricate stainless steel up to its melting point. This anomaly may be related to the fact that it requires only one molecular layer to lubricate steel compared with the three and five layers for copper and platinum respectively.

It is hoped that future work with an electron diffraction camera will give more information on these points.

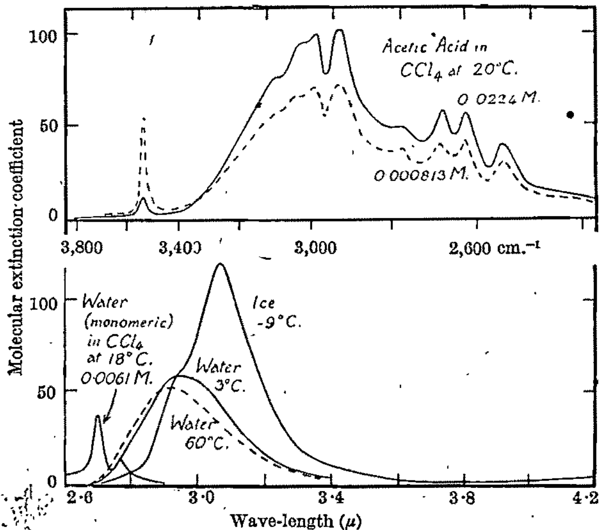
Hydrogen Bonding in Ice

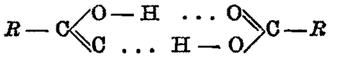
IN a recent communication in *Nature*[1], Prof. Max Born has discussed some features of the Raman spectrum of ice, more particularly in relation to the elastic constants. Since Prof. Born makes no use of the available infra-red measurements on ice[2] or of some earlier work on certain aspects of hydrogen bonding in ice, it seems worth while to recall some relevant data:

(1) Frequencies at 205–210 and 601 cm.$^{-1}$ occur in the Raman spectrum of ice[3,4] (calculated as 172 and 718 cm.$^{-1}$ by Prof. Born from the elastic constants of ice) and are also found in liquid water[3,4,5] less sharply defined at ~ 175 and ~ 500 cm.$^{-1}$. The lower frequency has for some years been identified as a hindered translation, and the higher as a hindered rotation or libration of an isolated water molecule in the surrounding water (or ice) structure. Bernal and Tamm[6] estimated these frequencies as 170 and 480 cm.$^{-1}$ in ice, and used them to calculate the specific heat of ice at the melting point.



(2) The broad Raman band of ice extending from 3,000 to 3,600 cm.$^{-1}$ is quite similar to the corresponding infra-red band (see accompanying graph), and both are generally regarded as being derived from the O—H vibrational frequencies in single molecules (3654 cm.$^{-1}$ in the Raman spectrum and 3,756 cm.$^{-1}$ in the infra-red spectrum), the parent frequency being reduced to a greater or lesser extent as a result of the influence of surrounding molecules in the liquid and solid states. Prof. Born appears to dislike this explanation; but the effect is quite characteristic of hydroxylic bodies generally (alcohols, phenols, carboxylic acids), and in each case the sharp O—H band observed for the monomeric substance becomes blurred, with a somewhat lower average frequency and greatly increased intensity of absorption as soon as association takes place. There is good evidence from infra-red measurements that the change of frequency from O—H (monomer) to O—H (polymer) is a measure of the strength of the hydrogen bond[7]; for example, when ice melts there is a shift of the O—H band to higher frequencies (see graph) corresponding to a reduction in the degree of association, and this effect continues steadily as the temperature of the water is increased.

A case of hydrogen bonding of considerable interest is afforded by acetic acid dissolved in carbon tetrachloride (see graph). The monomeric O—H band is clearly observed at 2·83 μ (3,534 cm.$^{-1}$), and rapidly diminishes with increasing concentration while the broad association band increases. The nature of the association between carboxylic acid molecules is established from electron diffraction measurements on formic acid[8]; the molecules are supposed to be associated in the form of a ring dimer



$$R-C\begin{matrix}\diagup O-H\ \ldots\ O\diagdown\\ \diagdown O\ \ldots\ H-O\diagup\end{matrix}C-R$$

with an O—H . . . O separation of 2·67 A. At low concentrations the rings split up into single molecules, and an equilibrium is set up.

$$R.\text{COOH}+R.\text{COOH} \rightleftarrows 2(R.\text{COOH}).$$

The difference between the association in ice and in acetic acid dissolved in carbon tetrachloride, as shown in the graph, is very marked, and clearly develops at very low concentrations in the latter case, due presumably to the stabilizing effect of the compact ring structure as compared with the less well-defined water complexes. The maximum possible effect on the O—H frequency of acetic acid as a result of hydrogen bonding would be obtained when the hydrogen atom occupies a mid-way position between two competing oxygen atoms, and in these circumstances the O—H distance would be approximately 1·335 A. instead of about 1 A. in the single acid molecules. A rough calculation shows that the frequency to be expected in this extreme case is ~ 2,330 cm.$^{-1}$ (~ 4·3 μ), and the curve shown does indicate a limiting value approaching this. No such extreme value is, however, found in ice, and the comparatively small frequency shift observed in this substance must mean that the average O—H distance is not greatly changed from the normal value in single molecules. A rough calculation indicates an average extension of the O—H bond in ice of perhaps 5 per cent.

(3) Prof. Born states that there is no line in the Raman spectrum of ice in the region between 800 and 2,900 cm.$^{-1}$; this is incorrect, as there is a Raman line at 2,225 cm.$^{-1}$ in ice at 0° C.[3]. The corresponding infra-red frequency is 2,222 cm.$^{-1}$ in ice at 0° C., while the values for water at 0° C. are ~ 2,170 and 2,149 cm.$^{-1}$, respectively. This frequency has been interpreted as a combination of the deformation frequency ν'_s (~ 1,650 in ice and water) and the frequency of hindered rotation ν_R previously mentioned[2,9]. Thus we have

$$\nu'_s + \nu_R = 1{,}644+601=2{,}245 \text{ for ice } (2{,}222 \text{ observed})$$

and

$$1{,}646+500 \doteq 2{,}146 \text{ for water } (2{,}128 \text{ observed at } 21^\circ \text{ C.}).$$

The ~ 2,150 cm.$^{-1}$ frequency in water (4·7 μ band) has a particularly strong temperature dependence, and this is attributed to the naturally large variation of ν_R with temperature.

Low-Pressure Electrical Discharges

SOME experiments awaiting publication show how remarkably easy it is to start high-frequency electrodeless discharges at pressures of the order of 1/100 or even 1/1,000 mm. of mercury in a uniform electric field. For a bulb of given size, the wave-lengths must be less than a certain value which is directly proportional to the diameter of the bulb. A rough working rule is that the maximum permissible wavelength (measured in metres) is four times the diameter of the bulb (measured in centimetres). If the pressure inside the bulb is increased from the above small value, this 'cut off' wave-length is also increased, and at a still higher pressure the 'cut off' disappears. At wave-lengths beyond the 'cut off' enormous voltages are required to get a discharge—if one can be got at all. The discharge starts most easily for wave-lengths from about one half to three quarters of the 'cut off' wave-length.

Provided the bulb is in a fairly uniform field (which is produced well enough by using circular parallel plates of diameter about one and a half times the bulb, with the bulb in between and close to both) a very moderate voltage will start the discharge. A peak value of the order of 100 volts will suffice whatever the size of the bulb if the above appropriate wave-lengths are used. When the discharge has once started, a peak value of considerably less will maintain it. All the power required can be got from a high-frequency generator running on 40–50 watts.

The most interesting fact is that the starting potential at these low pressures is independent of the nature of the gas, however carefully it is purified. Helium, hydrogen, air and mercury were used in bulbs varying from 3 cm. to 20 cm. in diameter, or flat-ended tubes a few centimetres long.

It follows that, at any rate initially, the large increase in the number of the few electrons present, necessary to start a discharge, when the high frequency is applied, cannot be due to gas ionization alone. The only other possibility of increase is secondary emission from the glass, and taking this as the main factor a simple theory is in good agreement with the main experimental results and with secondary-emission data given by Bruining[1].

Additional confirmation was the fact that if the glass surface is varied, the starting potentials are altered, in some cases very considerably. The theory was based on five simple considerations: (1) The velocity of electron impact on the glass has to be sufficient for each primary on the average to liberate more than one secondary. (2) The secondaries have a small emission velocity. (3) The phase has to be such that the secondaries cross the tube and are not pulled back by the alternating field to the glass from which they came. (4) That for constant increase in numbers this process must be repeated exactly every half-cycle. (5) That the electron velocities necessary to satisfy the above conditions are quite sufficient to ionize readily any gas by a collision.

The work was assisted by a grant from the Department of Scientific and Industrial Research.

Micro-Wave Solar Noise Observations During the Partial Eclipse of November 23, 1946

DURING the partial eclipse of the sun on November 23, 1946, a record of the reduction of radio-frequency energy emitted from the sun in the 2800-megacycle band was obtained at Ottawa, Canada. At this station, the eclipse commenced at 10.45.5 E.S.T., reached a maximum at 12.18 and ended at 13.51. At noon the sun was at an altitude of 23°, with its axis of rotation 19° east of north. The clear sky permitted the taking of photographs of the sun at the Dominion Observatory. Data from these are shown in Fig. 1.

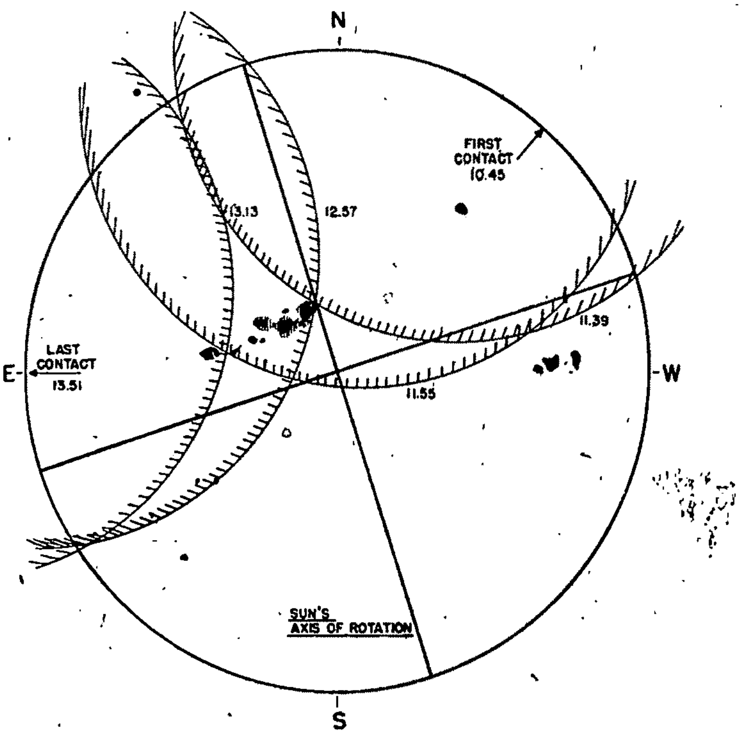

Fig. 1. LUNAR SHADOW POSITIONS OUTLINING ACTIVE REGION. DATA FROM DOMINION OBSERVATORY PHOTOGRAPHS

The sun's radiation, contained in two 5-megacycle bands centred about 2800 megacycles, was continuously received by a parabolic reflector, astronomically mounted and driven to follow the sun. Once every hour the drive was corrected manually to compensate for errors in following. The dipole antenna placed at the focus of the mirror was oriented so that its axis was parallel to the sun's axis of rotation; thus the plane of polarization of the received energy was fixed with respect to the sun's axis. The beam-width, 6° to the half-power points, allowed the total radiation from the sun and surrounding space to be received. The receiver, constructed after the manner of Dicke[1], measured over a short period of time the relative changes of energy to within 1 per cent. For a longer period of time, the sensitivity showed a gradual change. Calibration with a thermal load before and after the eclipse showed that the receiver sensitivity had decreased by 12 per cent. In allowing for this drift, it was assumed that the change was linear with time. At times shown by breaks in the record (Fig. 2), the antenna was moved from the sun in order to obtain the background as a reference point. The receiver output was used to drive a recording milliammeter.

Curve *A*, Fig. 2, shows the percentage antenna temperature smoothed to eliminate receiver noise and corrected for changes in sensitivity; curve *B* shows the percentage eclipsed area of the sun's photosphere. The observational results are: (1) a 15 per cent rise in the sun's temperature after the end of the eclipse; (2) small temperature fluctuations of about 7 per cent before the eclipse; (3) (*a*) a definite drop 3·0 min. before the moon made its first visible con-

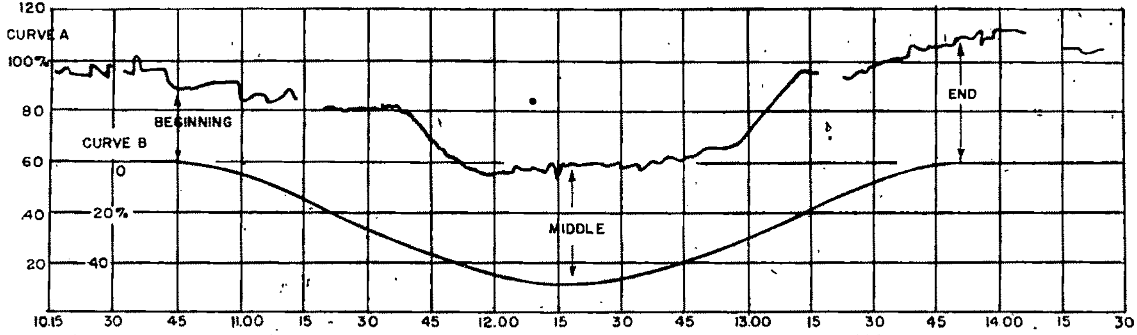

Fig. 2. CURVE *A*, VARIATION OF SOLAR NOISE DURING ECLIPSE, NOVEMBER 23, 1946. CURVE *B*, ECLIPSED AREA OF SUN

tact. At this instant the moon's edge was 1·05 times the sun's radius from the centre of the sun. Details of change are shown in the table below; (3) a gradual return during the last part of the eclipse; (4) a decrease occurring at 11.39 and an increase at 12.57 E.S.T.

Minutes before contact	Percentage reduction

−2	9·5

Since the discovery of solar noise by Southworth[2] and Reber[3], and the subsequent discovery by Pawsey, Payne-Scott and McCready[4] that the sunspot areas are particularly active noise generators in a lower-frequency region (about 200 megacycles), records obtained during a solar eclipse will give information regarding the noise distribution over the sun's surface. In the microwave region (24,000 megacycles) reference should be made to the results of Dicke and Beringer[5] obtained during the eclipse of 1945. Fortunately, during the present eclipse, a large group of spots was obscured by the moon at 11.39 and uncovered at 12.57. It is believed that this is the interpretation of the sudden change of energy (25 per cent) during the middle of the eclipse marked by the fall and rise at the times indicated. The noise-generating region, totalling 2·2 per cent of the sun's projected surface and containing the sunspot group, is outlined by the four lunar shadows shown in Fig. 1. With the present data, this area has an equivalent temperature of $1\cdot5 \times 10^{6}$° K. in excess of the average surface temperature of $5\cdot6 \times 10^{4}$° K. This average is obtained for the eclipsed portion of the sun disregarding the spot area.

Before the first contact, the substantial reduction in energy might indicate that the source is in the space surrounding the sun, either from the corona or from a prominence. Calculation of the equivalent temperature of the crescent-shaped area swept out by the moon during the three minutes before contact gives 3×10^{6}° K. From the rate at which the temperature fell, most of the energy is produced in a region just off the visible limb. Photographic evidence for such a local disturbance has not yet been obtained.

No obvious correlation has been obtained between the disappearance of the isolated spot in the north-east quadrant of the sun and any sudden drops in radiation. The large group south of the equator was not eclipsed, although an active region surrounding this spot could have been partially eclipsed for a short time.

I much appreciate the assistance given by members of the Dominion Observatory.

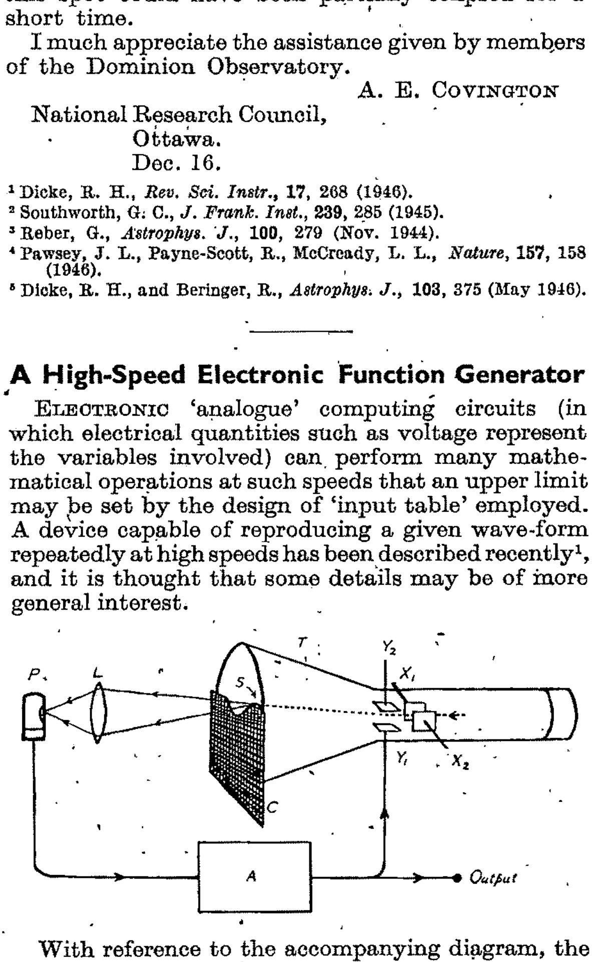
A High-Speed Electronic Function Generator

ELECTRONIC 'analogue' computing circuits (in which electrical quantities such as voltage represent the variables involved) can perform many mathematical operations at such speeds that an upper limit may be set by the design of 'input table' employed. A device capable of reproducing a given wave-form repeatedly at high speeds has been described recently[1], and it is thought that some details may be of more general interest.



With reference to the accompanying diagram, the edge of an opaque card *C* is cut to the required shape, and the card placed over the face of a cathode-ray tube *T*. A lens *L* focuses light from the spot *S* on a photocell *P*, the output of which is coupled through an amplifier *A* to one of the deflector plates of the tube Y_1, in such a sense that an *increase* in the intensity of light would deflect *S towards* the region of the screen obscured by *C*.

Given suitable optical shielding and sufficient overall gain, *S* will be constrained to adopt a position partially obscured by *C*, and will follow the curved edge of *C* if subjected to *X*-deflexion. (It must be noted, however, that the persistence of screen afterglow corresponds to an integrating term in the feed-back loop, setting an upper limit both to the frequency response and to the gain of A in accordance with Nyquist's criterion of stability[2].

If $y = F(x)$ be the equation of the curved edge relative to the *deflexion axis*, this will also (very nearly) be the equation of S, so that if S be deflected linearly with time in the X-direction, the output wave-form will be an electrical replica of the curve. More precisely, if the co-ordinates of S are (x, y), and voltages on the Y_1, Y_2, X_1, X_2 plates are p, q, r and s respectively, we have

$$p - q = \frac{y}{k_1}; \quad r - s = \frac{x}{k_2},$$

where k_1 and k_2 are normally constant, being inversely proportional to the accelerating voltage V of the tube. Hence the output voltage p will obey the law $p = q + \frac{1}{k_1} . F[k_2(r - s)]$, where q, r and s (and to a limited extent, k_1 or k_2) are independent variables, and F can include rotation and displacement of the axes to which the curve was originally drawn.

Since one can also set either r or s equal to p or q, the device is capable of generating quite a variety of functions, at a speed limited only by the frequency response of the system, conditioned mainly by the type of screen employed. Special screens are available with afterglow times of the order of microseconds, so that a 'scan time' of the order of milliseconds is feasible, and virtually continuous cathode-ray tube presentation of the output of a differential analyser using such a device should be possible, with obvious advantages when dealing with, for example, equations having variable coefficients. Other obvious possibilities are suggested by the ease with which functions such as log x, e^x, etc., can be generated, and are at present being investigated.

Latent Energy and After-glow in Flame Gases

The energy present in long-lived latent form in flame gases resides, I think, in very stable abnormal triatomic molecules formed during combustion. The amount of latent energy in flame gases resulting from combustion at constant pressure is rarely less than about 15 per cent of the heat of combustion, and, if this view is correct, the numbers of abnormal molecules must be large.

It has been suggested, by way of criticism of this, that the luminosity (after-glow) of flame gases indicates that there can only be an exceedingly small concentration of excited molecules. But this suggestion fails to account for the remarkable persistence of the after-glow in all cases where cooling of the flame gases does not take place rapidly. The numerous flame photographs taken by various observers show this clearly[1], and to the eye, of course, it persists for much longer than the photographs indicate. Indeed, after the explosion of a perfectly mixed inflammable mixture in a large vessel, it has been seen to exist for 0·4 sec., and there seems to be little doubt that were it possible to isolate hot flame gases away from surface, and under conditions such that cooling did not take place, it would remain for a time which could be measured in minutes. Furthermore, flame gases after being cooled to darkness by adiabatic expansion can be made luminous again by adiabatic compression[2].

It does not seem to be possible to account for the persistence of the after-glow unless it is assumed that large numbers of abnormal molecules of great stability are formed during combustion (just as was inferred from latent energy measurements), and that the *rate* at which these molecules reach the ground-state is exceedingly small. Individual molecules would not appear to possess sufficient energy for the emission of light quanta, and it seems probable that this can only happen during the infrequent collisions of sufficiently energized pairs of them. The rate at which such collisions take place, and therefore the intensity of the after-glow, depends both upon the concentration of the abnormal molecules, which varies with the amount of latent energy, and upon the flame gas temperature. This is in accord with experiment[3].

The hypothesis outlined above may also serve to explain the continuous background observed in carbon-monoxide and hydrogen flame gas spectra.

There is, I think, now no doubt that even in ordinary open flame gases some 25 per cent of the heat of combustion is in the form of latent energy and the abnormal dissociation[4] which results from it. This energy is released when the flame gases impinge upon surface.

It is hoped to publish shortly the evidence for this.

"Turbulent Flow in Alluvium"

Sir Claude Inglis, in his letter published in *Nature* of October 19, p. 552, remarks that my formulæ for alluvial flow are based on two fundamental relationships. It would be more correct to state that two independent fundamental equations are necessary to a complete solution, and that each of these equations consists of an empirical correlation of dimensionless numbers or 'arguments', derived from the essential variables. Dr. White has produced a partial solution, which effectively ignores the Reynolds number. The following solution appears to be complete.

There appear to be seven essential variables involved, namely :

P	wetted perimeter	μ	viscosity of water
R	hydraulic mean depth	g	acceleration due to gravity
V	mean velocity		
ρ	density of water	$i = gRS$	energy gradient

These are the traditional variables. It will be observed that the density, grade and quantity of the charge do not enter within this framework: They are implicit in the values assumed by V, R and S for a given value of Q the discharge. These seven variables demand the following four dimensionless arguments:

$$V^2/gRS\ ;\quad V^2/gR\ ;\quad RV/\mu\ ;\quad P/R,$$

in which the slope S has been inserted by substitution.

Of these four arguments any one may be expressed as an empirical function of any two of the remaining three. Two equations thus afford a complete solution, and they may be written:

$$P/R \;=\; \tfrac{1}{2}\,(V^2/gR)^{1/3}\,(RV/\mu)^{1/3} \qquad (A)$$
$$V^2/gRS = \tfrac{1}{4}\,(V^2/gR)^{-2/3}\,(RV/\mu)^{1/3}. \qquad (B)$$

These two equations reduce to

$$P = 2{\cdot}78Q^{1/2},$$

and

$$V = 15{\cdot}8R^{2/3}\,S^{1/3},$$

when the temperature of the water is 30° C.

The coefficients $\tfrac{1}{2}$ and $\tfrac{1}{4}$ respectively in the two basic equations appear to be pure numbers under ideal conditions.

On elimination of the Reynolds number from the basic equations, my equation published in *Nature* of August 3, p. 166, immediately results, namely:

$$\begin{aligned} V^2/gRS &= \tfrac{1}{2}\,(gR/V^2)\,.\,P/R \\ &= \tfrac{1}{2}\,gP/V^2. \end{aligned} \qquad (C)$$

The manner in which the three arguments enter should be noted. The new Froude number V^2/gP is none other than the usual Froude number V^2/gR divided by the shape number P/R. Similarly the 'White' number $ag^{2/5}/Q^{4/5}$ raised to the fifth power is none other than $P/R\ .\ (gR/V^2)^2$.

It would appear desirable, when making an attack on any dimensional problem, to express the new dimensionless numbers involved, if possible, in terms of more familiar dimensionless arguments. When this is done, the precise nature of the assumptions made is more readily appreciated.

The difficulties experienced in the past in the dimensional treatment of alluvial channels in loose material have arisen from the fact that the full implications of an ideal self-generating channel have not been understood. Old methods have been employed to solve a new problem. The reappearance of the old familiar dimensionless arguments, or numbers, is, however, reassuring.

Submarine Tubes for Levelling

THE ocean surface deviates from the geoid, that is, from a level surface, by an amount probably exceeding one metre even if short-period disturbances such as waves and tides are eliminated. It therefore cannot serve as a datum for precise levelling. Coasts separated by water can, however, be joined by hydrostatic levelling, recently described by Nørlund. In 1938 he 'bridged' the Store Belt[1] in Denmark with a water-filled submarine tube of length 18 km. and inside diameter 1 cm.; the greatest depth was 60 m. Observations of atmospheric pressure at each end and of temperature distribution along the tube served to determine the difference in level between the water surfaces inside each end. In 1939 he joined the spirit-level networks of Denmark and Sweden by means of a 4·2 km. submarine tube beneath Oresund[2].

Nørlund's new method can furnish information needed in physical oceanography. The relations between current and slope of the ocean surface, except the part due to difference in atmospheric pressure, are the same as the more widely known relations between wind and slope of an isobaric surface in the atmosphere. Previous knowledge about the level or geopotential of the ocean surface has depended entirely upon the spirit-level method and the oceanographic method. The latter method gives the difference in geopotential between point 1 and point 2 in the form

$$\varphi_2 - \varphi_1 = -\int_{p_1}^{p_2} \alpha\, dp\,;$$

the integral of specific volume α with respect to pressure p from point 1 to point 2 must be carried out along an instantaneous path consisting only of (*a*) vertical lines, and (*b*) lines along which the horizontal component of the pressure gradient vanishes. The distribution of specific volume is obtained by ordinary oceanographic methods. The path is so chosen that non-vertical parts are at great depths, where condition (*b*) can be expected to be approximately fulfilled.

Hydrostatic levelling is similar to oceanographic levelling, but has the advantage that the water in the tube comes to rest or oscillates about a position of equilibrium, so that condition (*b*) is necessarily fulfilled. The difference in geopotential between the two ends can, therefore, be computed from the equation above. Since the tube is filled with a liquid of known pressure-volume-temperature relationship, the necessary data are obtained by measuring the pressures p_1 and p_2 inside the ends, and the distributions of temperature and of approximate depth along the tube.

Hydrostatic levelling across the Straits of Florida would provide basic information concerning the Florida Current, the source of the Gulf Stream. The distance from Miami, Fla., to Cat Cay, B.W.I., is 82 km.; the greatest intervening depth is about 900 m.

Not only can any two coastal points be joined by hydrostatic levelling, but also any coastal point can be joined with any point on the ocean surface if a tube holding a known liquid starts from the coastal point and has an open end on the bottom near the ocean point. In addition to the pressure p_1 at the coastal point and the atmospheric pressure p_2 at the ocean point, and to the temperature distribution along the tube, the distribution of specific volume below the ocean point must be measured. The path of integration lies from p_1 through the length of tube and vertically upward through the ocean water to p_2.

Activation of Paludrine *in vitro*

PALUDRINE has recently been introduced into clinical medicine as a drug which is highly active against most species of malaria parasite ; its formula is

Tonkin[1], in this laboratory, investigated its effect on the exoerythrocytic forms of *P. gallinaceum* grown in tissue culture, and found that it had no action upon the parasites in the highest concentrations (2–5 mgm. per litre) tolerated by the macrophages. Since this concentration is many times greater than that which is believed to be present in the plasma in human therapy (probably about 0·3 mgm. per litre) its inactivity was surprising ; and the action of paludrine *in vitro* has been investigated further using *P. cynomolgi* of monkeys, and the exoerythrocytic forms of *P. gallinaceum* grown in tissue culture, as test organisms. *P. cynomolgi* was cultured *in vitro* at 37° C. by a modification of Bass and John's technique and, 41 hours later, smears were made and stained with Giemsa. The parasites found were classified according to the number of pieces of chromatin present, and the resulting differential counts are shown in the accompanying table. The figures indicate the percentage of parasites containing 1, 2–3, 4–5 pieces of chromatin, etc., respectively.

	1	2–3	4–5	Greater than 5	Degenerate	Gametocytes
Original blood	90	10	0	0	0	0
Control *A*	0	6	31	49	10	4
Paludrine added to serum *A*						
2 mgm. per litre	7	27	23	26	9	8
1 mgm. per litre	7	25	26	31	4	7
Paludrine serum (*B*)	54	23	5	5	10	3
,, ,, 1/4	28	46	21	2	0	3
,, ,, 1/16	24	42	16	2	8	8
,, ,, 1/64	18	42	24	6	2	8

Monkey *A* was the donor which provided the parasites, and the serum for the controls and for dilution of serum *B*, etc. Serum *B* came from a monkey (weighing 3·4 kgm.) which had received two intramuscular injections, each of 50 mgm. paludrine acetate, 21 and 5 hours previously. Previous experiments had shown that the serum of this monkey had no injurious effects on malaria parasites obtained from monkey *A*.

The table shows that the parasites were originally present as forms with only one piece of chromatin ; most of them were small rings. After 41 hours a large proportion in the control tube *A* had developed so that 49 per cent now possessed more than five pieces of chromatin (at complete schizogony there are sixteen pieces). Very similar development had occurred in the tubes to which paludrine had been added in relatively high concentration. In the tubes containing serum *B* from the monkey treated with paludrine, development of the parasite was inhibited to a considerable extent, so that 6 per cent or less of the parasites had reached the stage of more than five pieces of chromatin. (Other degenerative changes, which cannot easily be expressed in quantitative terms, were also present in the parasites of these tubes.) This inhibition was marked even in the tube which contained only 1 part of serum *B* diluted with 63 parts of *A*.

Similar results have been obtained in tissue cultures of the exoerythrocytic forms of *P. gallinaceum*. Serum from a fowl treated with paludrine possesses an antiplasmodial action which is absent when paludrine is added directly to the cultures. These findings are in agreement with those of Black[2], who reported that serum from a patient treated with paludrine arrested the development of trophozoites of *P. falciparum* when cultured *in vitro* ; he did not examine the effect of adding paludrine directly to his cultures. It is concluded that probably paludrine does not itself possess antimalarial action, but that it is converted by the body into something which is active.

An Œstrogenic Substance in Pollen-grains of Date Palm Tree *Phœnix dactylifera* L., Palmæ

THE term œstrogen or œstrin is now used to designate the whole group of œstrus-inducing substances irrespective of its constitution or origin.

The natural œstrogenic hormones are of wide occurrence, and although œstrogenic substances have been found in mineral sources yet none of naturally occurring œstrogenic hormones has been detected among them. A surprising discovery was that œstrin occurs in the vegetable kingdom. Butenandt and Jacobi[1] succeeded in isolating pure œstrone from a palm-kernel extract, and Skarżyński[2] obtained from female willow flowers a crystallizate of pure œstriol, the hormone hydrate. The substances isolated from the plants produced a typical œstrus response in ovariectomized rats.

We have found an œstrogenic substance in pollen-grains of the palm plant. The active part is found in the non-saponified fraction of the oil extracted from the dry pollens. A water-soluble form of this active part was made according to Marrian's method and tested biologically. A batch of eleven ovariectomized rats weighing 140–160 gm. were divided into three groups.

Group 1. Three rats received no supplement and used as negative controls.

Group 2. Three rats injected with pure œstradiol dipropionate and used as positive controls.

Group 3. Five rats injected with the water-soluble form obtained from the palm pollen-grains in four doses over a period of twenty-four hours.

All groups were kept under observation and showed no cycles during a preparatory period of two weeks, after which both groups 2 and 3, which were injected with the active material at the same time, showed simultaneously identical complete cornification of the vaginal smear twenty-four hours after the last injection.

This proved the occurrence of a biologically active œstrogenic substance in the pollen-grains of the palm plant.

A spectroscopic examination of this fraction dissolved in absolute alcohol showed an absorption band in the ultra-violet region near 282 mμ, as compared with the 280 mμ of œstrone.

On addition of concentrated sulphuric acid to a chloroformic solution of this fraction, an orange coloration is observed which is changed to a red solution on adding a few drops of water and heating in a boiling water bath (Kober's test for œstrone[3]). The active part also gives a red coloration with Marrian's phenol-sulphonic acid reagent[4] specific for œstrone.

This problem was suggested by H. E. Dr. S. Azmy Pasha, professor of medicine. Further work is in progress to identify and to isolate this biologically active œstrogenic material.

Mauthner's Cells in the Larvæ of Anuran Amphibia

THE cells of Mauthner occur in the medulla oblongata of many teleost fishes, Dipnoi and urodele Amphibia, where they have been widely studied. On the other hand, their occurrence in the larvæ of anuran Amphibia has been disputed for many years, and to judge from the literature most attempts to find them have failed. Szepsenwol[1] claims to have found them in the larvæ of *Rana fusca* and *Bombinator pachypus*; but his account, unfortunately published without illustration, does not appear to have received general recognition.

With the aid of a new silver-staining method, an account of which is now in the press, I have recently obtained clear evidence for the regular occurrence of a single pair of Mauthner's cells in 22 mm. larvæ of *R. fusca*. With regard to the size and position of these cells, and the distribution of their dendritic processes, I am in agreement with the account given by Szepsenwol. The cells are best seen in thick (20–25 μ) transverse sections of the medulla, near the entry of the auditory nerve roots.

My observations on that part of the axon process which is usually described as 'Mauthner's fibre' differ considerably from Szepsenwol's description. The latter states that, in *R. fusca*, Mauthner's fibres are single processes. Against this, I have found that, before decussating, each fibre divides into two similar and thinner fibres. Each of these decussates separately with its fellow from the opposite side of the medulla, and becomes contralateral. The two decussations are equidistant from Mauthner's cells and occur one above the other. Posteriorly, the two contralateral fibres formed by each Mauthner's cell run beside the fasciculus longitudinalis medialis to the tail. In 22 mm. larvæ the Mauthner fibres are about twice as thick as the fibres of the fasciculus longitudinalis medialis, and have a more marked affinity for silver.

During larval life up to the 18–22 mm. stage (approximately), the growth of the Mauthner system is accompanied by the development of Rohon-Beard sensory cells, arranged as a dorsally situated column along the spinal cord. In later larval life, the growth of both these specifically larval components of the central nervous system is arrested. The Rohon-Beard cells rapidly undergo degeneration, while the Mauthner system persists without any further considerable differentiation.

Ethical Aspects of the Development of Atomic Energy

BOTH the letter from Lionel Curtis in *Nature* of January 25 and the editorial article in the issue of December 21 appeal for "the fact-finding method of science" to be brought "into the political sphere"; but both, it seems to me, ignore the most significant fact in the world situation.

If it were true, in any immediate sense at least, that "The future of humanity depends on the three great Powers, not less than others, placing themselves strictly under the judgment and the surveillance of the rest of the world", then there would be no future for humanity. For such a dictum ignores the fact that one part of the world has, or is developing, a planned economy which involves great restriction or even abolition of the freedom of 'private enterprise', while the other part declares such freedom to be the essential core of civilization. There are intermediate positions, of course, but the two extremes, represented by the U.S.A. and the U.S.S.R., will not submit to each other's judgment in these matters.

A "strong international democracy" in such circumstances is impossible, and those who declare it to be essential merely make the side which would be in a minority, if such a democracy could be brought into existence, feel that the real intention is to impose on them an economic system they abhor. It is perhaps significant for a scientific investigator that all such declarations do, in fact, come from the side which would at present be in a majority.

I think such an international democracy will come into existence when the present polarization of social structure and ideas has ceased to exist. But that will not be in time to solve our present problems. What, then, can be done?

The essential thing is to see that the conflict which undoubtedly exists between the two parts of the world is resolved by friendly competition and not by armed force. At present it is only too obvious that each side suspects the other of attempting to achieve its domination by armed force. The great task facing us is to dispel that suspicion and create the conditions for peaceful rivalry between the two systems; to see which can, in the long run, give the common man more of the things, material and spiritual, which he desires.

What is required is a declaration by all the Powers that they will not use, make or keep a stock of atomic bombs or other weapons of mass destruction. While this is obviously insufficient by itself, it would help to allay suspicions and pave the way for general disarmament, in which the question of control of atomic energy would take its logical place along with the general control of disarmament.

RELEASE OF INFORMATION ON ATOMIC ENERGY

IT is well known that the scientific work leading to the design of an atomic bomb was carried out under conditions of the strictest secrecy, and even fundamental scientific information obtained in this connexion was jealously guarded. It is natural that under post-war conditions much of this information can be released, but there are obvious difficulties in publishing it in the normal way.

The work was done as a joint project, shared by the American, British and Canadian Governments. Each country is considering its material independently, though on an internationally agreed basis as to what may and what may not be released. Most of the material is in the form of hastily written reports, and there is a reluctance on the part of authors to go back to this old material and to rewrite it in a form suitable for publication. Moreover, in many cases there would be independent publication of similar material from the United States or Canada. In view, too, of the continuing paper shortage, journals would find difficulty in publishing all the material, even if it were offered to them.

It has consequently been decided that where British information is declassified, copies of the reports shall be deposited in the Science Library at South Kensington, London, and the titles, of which a list follows, announced to the scientific public. So far as supplies permit, copies will be lent to responsible workers if they apply to the Technical Records Section, Department of Atomic Energy, Shell Mex House, Strand, London, W.C.2.

SCIENTIFIC RESEARCH IN THE PACIFIC AREA

THE *Proceedings* of the Pacific Science Conference of the National Research Council, held at Washington, D.C., June 6–8, 1946, and now published as Bulletin No. 114 of the National Research Council (Washington, D.C.: National Academy of Sciences), includes reports of the opening addresses and of the various sessions, the specific and general recommendations of the Conference, the proposed organisation of the Pacific Science Survey and the recommendations relating to international co-operation.

The objectives of the Conference were to form an effective organisation of American men of science interested in the Pacific, to encourage and assist scientific research and activities in that area, and to further international co-operation along these lines. These objectives were detailed more specifically by Dr. Douglas L. Oliver at the opening session, and the permanent organisation which the Conference recommended the National Research Council should establish under some such name as the Pacific Science Survey contemplates six divisions, for anthropological sciences (including human geography), earth sciences, oceanography and meteorology, plant sciences, public health and medicine, and zoological sciences, respectively, each represented by a committee within the appropriate division of the National Research Council, the chairmen of these committees, with three others, constituting the Pacific Science Board. A co-ordinated programme of scientific research for the Pacific Islands, under American or foreign administration, has been formulated, and recommendations are detailed in the report under each of the divisional heads given above.

The pamphlet also includes a number of general recommendations regarding the release of materials and scientific information, the conservation of flora and fauna, and the use of insecticides, herbicides, etc., which might disturb the biological balance, the interchange of information on the physiology, biochemistry and biophysics of plants of importance in the Pacific area; and the establishment of base stations for scientific research in Hawaii, Guam and the Galapagos Islands, as well as floating stations, advance base stations for both marine and terrestrial research on various types of islands and at the extremes of environmental conditions and liaison stations in the Solomon Islands, Australian and Dutch New Guinea, French Oceania, Indonesia, the Philippines and the Galapagos. A survey of the state of our knowledge in the various fields of science in the Pacific, including a bibliography of the basic contributions, and documentation centres at Washington and Honolulu are also recommended.

Specific recommendations pertaining to international co-operation relate to the establishment of visitors' facilities at the principal centres, collaboration with interested institutions and individuals, American and foreign, in the preparation of a series of regional Floras, and encouragement of field-work in areas for which the data are inadequate. The establishment by the Government of the Netherland Indies of a scientific research station at Hollandia, Dutch New Guinea, is also recommended. Other matters discussed are the formation of international committees for the correlation and standardization of nomenclature and methods of measurement, extension of the survey of the Algæ and algal resources of Philippine and Indonesian waters to cover the Pacific, and the establishment of a scientific centre in the Philippines, supported by private funds.

FREE-PISTON COMPRESSOR-ENGINES

THE paper by H. O. Farmer on "Free-Piston Compressor-Engines", read before the Institution of Mechanical Engineers on December 6, must have been for many their first introduction to the subject, as this type of engine has received little publicity and has only just reached the production stage.

The free-piston compressor-engine, in its production form, is a reciprocating air compressor driven by a reciprocating two-stroke compression-ignition (or Diesel) engine. The outstanding feature is that neither the engine nor the compressor has the conventional rotating crankshaft; instead, the engine and compressor cylinders are arranged in line and the pistons are coupled directly. A normal engine has a flywheel which supplies the energy for the compression stroke; but in the free-piston engine, which has no flywheel, energy is supplied by the compressed air remaining in the compressor cylinder clearance space. This action is assisted in most free-piston engines by a separate 'cushion' cylinder with a closed end.

In order to improve the balance, there is usually a piston at each end of the engine cylinder, one being coupled directly to the compressor piston and the other to the 'cushion' piston; these two moving systems are coupled by a light linkage so that their displacements are equal and opposite. The underside of the compressor piston is used to pump scavenging air for the engine cylinder. This arrangement has all the very attractive features of the opposed-piston, two-stroke, supercharged, compression-ignition engine without the complication and expense of the connecting rods and rotating parts associated with conventional designs.

The amount of fuel injected is varied automatically by a governor so as to keep the output air pressure constant; the effect of varying the air demand being to change the stroke of the plant (the stroke is not fixed as in a normal plant). The frequency of the cycles remains nearly constant, and is 1,000 cycles per minute in one case quoted in the paper.

Starting is accomplished by bringing the engine pistons together suddenly. In small engines this is done by a spring, previously compressed manually through a handle and gearing; in larger engines a charge of compressed air is admitted to the 'cushion' cylinder. Another interesting detail is the method of driving rotating accessories such as the cooling fan and the water pump; the main reciprocating parts drive a plunger-type oil pump; this oil then drives a gear-type oil motor which provides the small power required.

A possibility which is being actively investigated is the use of a free-piston compressor-engine, instead of the usual rotary air compressor, in conjunction with a gas turbine for power purposes. The whole of the air pumped by the compressor cylinder is fed to the engine cylinder for scavenging and supercharging, and the hot exhaust gas, at comparatively high pressure, passes through a gas turbine. It is claimed that the very high overall efficiency of 41 per cent is obtainable.

Free-piston compressor-engines were largely developed by Pescara, who started work on them in France in 1922. In Great Britain their development was encouraged by the Services; the first engines were ordered for the Navy and later ones for the Army.

TREPHOCYTES AND TREPHOCYTOSIS

DR. LIEBMAN'S monograph, "On Trephocytes and Trephocytosis; a Study on the Role of Leucocytes in Nutrition and Growth" (*Growth*, **10**, 291; 1946), concerns a neglected field of invertebrate hæmatology, and combines a comprehensive review of the literature with a record of his own extensive studies. Attention is focused on leucocytic elements that contain inclusion bodies (granules, spherules and pigment), but which, according to the evidence, have no phagocytic function. The author advances a well-substantiated view that the inclusion bodies are elaborated inside these cells, which he calls 'trephocytes', and that they are discharged and utilized as nutrient material in regions of increased metabolic activity. Hence the concept of trephocytosis, which is thought to be the main function of these cells, as opposed to phagocytosis, which, in the author's opinion, may well be the main task of hyaline 'lymphoidocytes'. On the comparative side, a parallel is drawn between the trephocytes of invertebrates and the mast cells of vertebrates.

The attitude of the author is characterized by a justified reluctance to apply, without reservation, the teleological line of thought imposed by mammalian 'defence' physiology and, consequently, a caution in attributing phagocytic properties to elements which do not seem to possess any.

Of particular interest are the author's current studies in Tunicates, and especially his observations made in Sipunculids and Polychætes, where some blood cells reveal intermediate characteristics between leucocytes with inclusions and erythrocytes. A more detailed account of this work may well prove of great value for comparative hæmatology.

FORTHCOMING EVENTS

Monday, March 31

Palæontographical Society (in the Geological Survey Museum, Exhibition Road, London, S.W.7), at 11 a.m.—Centenary Meeting; Prof. H. L. Hawkins, F.R.S.: Commemorative address: at 2.30 p.m.—Mr. C. P. Chatwin: "The Story of Fossils".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Developments in Fractional Horse-Power Motors" (to be opened by Mr. A. N. D. Kerr).

Tuesday, April 1

Sheffield Metallurgical Association (at 198 West Street, Sheffield), at 7 p.m.—A representative of the Mond Nickel Co., Ltd.: "Isothermal Transformations".

Television Society (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2).—Annual General Meeting.

Wednesday, April 2

Institute of Fuel, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Annual General Meeting.

SCIENCE NEWS ASSOCIATION
Office of
CALCUTTA

Institution of Civil Engineers, North-Western Association (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. F. N. Sparkes: "Some Defects in Concrete Roads—Causes and Remedies".

Society of Dyers and Colourists, Midlands Section (in Room 104, College of Art and Technology, Leicester), at 7 p.m.—Dr. G. L. Royer: "Studies on Wool Dyeing: Comparison of Methods for Applying Chrome Dyes".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer or **Lecturer in Soils and Manures**, and an **Assistant Lecturer in Biochemistry**, at the Massey Agricultural College, Palmerston North—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (April 9).

Senior Lecturer and a **Lecturer in the Department of Anatomy**—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (April 15).

USE OF THE LAND IN BRITAIN

SINCE the appearance in 1944 of the White Paper on the utilization of land issued by the Coalition Government, it has been fairly certain that any proposals for a central planning authority and for dealing with the difficult problems of compensation and betterment advanced by the Government of the day would be controversial. Of the Planning Bill introduced by Mr. Silkin, it must be said that while it goes a long way towards establishing a workable system planning the use of the land and meeting the fundamental requirements, it is not unreasonably controversial. Dispute as to the price the community should pay for extinguishing the development rights of private owners of land does not alter the plain fact that the extinction of those rights removes the largest single impediment to planning of the use of land on national lines. Moreover, the decision not to transfer to national ownership all land about to be developed, as was recommended by the Uthwatt Committee, and to levy a betterment charge only when a change of land use occurs, in place of a levy on all increments of site value, may add indirectly to the cost of good planning but should not seriously hamper it. The planning sections of the Bill appear to concede virtually all that planners and local authorities have demanded for a generation, and the wide extension of Exchequer grants to local authorities should banish the last remaining fear of local authorities that the policy of systematic urban dispersal, extension of open space in central areas, and the conversion of land to more socially valuable uses, although less remunerative financially, will involve them in financial losses and compensation charges which they cannot face.

Amid the mass of detail with which we are not appropriately concerned here, there are at least two points which claim attention. The first of these concerns the basis of planning. Development without prior permission is in future prohibited, even when a local planning authority is to be responsible for development. Every local planning authority must first survey the area and prepare a development plan indicating the manner in which it proposes that land in that area should be used, and the stages by which any such development is to be carried out. The planning process is to be flexible, dynamic and positive, and doubts as to the adequacy of the unified control proposed were largely—but not entirely—resolved by Mr. Silkin's declaration, in moving the second reading of the Bill, of his intention to use fairly freely his power to create joint planning boards from the one hundred and forty-six counties and county boroughs which are to be the main and primary planning instruments.

These authorities are given three years in which to prepare their broad development plans. Such plans are to show which towns and villages are suitable for expansion, and which can best be kept to their present size ; the direction in which a city will expand ; the area to be preserved as an agricultural green belt and the area to be allotted to industry and to housing. In filling in the detail over smaller areas, when development is about to take place, much of the work of enforcement and detailed control will be delegated to the smaller authorities. The central authority will knit development plans into regional and national patterns and will participate in all stages of planning, and local authorities must reconsider their plans at least once in every five years.

While, however, the local authorities are given the legal powers to march with their new responsibilities, as well as the financial resources, there can be no question as to the strain which will be imposed upon many of them, and the first question that arises is the provision of adequate trained staff to discharge the new planning functions and responsibilities. It was stated in the debate that local authorities already need 1,800 more men with technical architectural knowledge than they can get—a figure equal to the total membership of the Town Planning Institute, including students. This is a fresh demand on trained man-power which cannot be ignored, even if in some areas a great deal has already been done to provide the basic surveys required. It will be essential for the local and regional planning authorities to make the fullest possible use of such local surveys by voluntary bodies and to foster further surveys by such bodies as Nuffield College, the West Midland Group on Post-War Reconstruction and Planning, the Northern Industrial Group, and local universities.

The three years in which the local authorities have to prepare development schemes will clearly be too short, even if no difficulty were likely to be experienced in recruiting the additional planning staff and in training that staff in a new tradition which will equip them to understand and to mould the social and economic fabric of the nation, unless the fullest possible help and co-operation is secured from the many who are willing to give it. Mr. Silkin himself recognized the need for associating the universities in particular, not merely with the training of the new type of planner required to carry out this broader conception of planning, but also with research into the economic and social problems of their surrounding areas, as has been done earlier by the Board of Trade. Due regard must, of course, be had to the proper limits of academic studies; but even so, this may be much the most important contribution that the universities can make in the immediate future to the planning of Britain, apart from their continuing function of supplying the nation with men and women trained to take balanced views and imaginatively alive to the human no less than to the technical issues in the problems with which they are called upon to deal.

We can scarcely expect the universities to make an immediate contribution to the supply of the large numbers of new town-planners who will be required, for the University of Durham alone provides a degree course in town and country planning. Indeed, not many of them are likely to be university graduates. Nevertheless, as Mr. Silkin rightly said, the co-operation of economists, geographers, sociologists and others will be required, and the universities can do something more to promote that informed and interested public opinion which is an essential condition of good planning, as well as the supply of first-rate administrators to give effect to the plans. The Bill might well have contained more evidence of the Minister's desire for such co-operation. The immense amount of material which the Bill contains is a further reason for affording the ordinary citizen ample opportunity to express his views. There could be no greater mistake than to attempt to curtail public discussion and informed criticism of the many complex issues which are raised.

The importance of such public discussion is enhanced by a second feature of the Bill which should be noted by scientific workers because of its implications for them. Comprehensive as are its planning provisions, and thoroughly as they remove the main obstacles to the rational and orderly development of the land of Britain—the compensation bogey, the lack of finance for local authorities, the absence of powers of State planning and development—there is one serious omission. Land held by Government departments, except when leased to private persons, will escape all local planning control, and the Minister himself has no authority over the use of land by other Government departments or by statutory undertakings, and no control over the location of industry. There is no provision for harmonizing the planning activities of the many Government departments which will retain power to acquire land, or to reconcile differences regarding the use of land between the Ministry responsible for planning and such departments; and inasmuch as the control of the location of industry is by the Bill itself to be vested in the Board of Trade, the influence of the Board on the planning and development of the community may be as great as that of the Ministry of Planning itself.

How serious is such a position has been well brought out in the recent inquiry into the proposal to dam Ennerdale Water, and in the current debate regarding the acquisition by the Services of land for training areas. The Standing Committee on National Parks, which represents the Councils for the Preservation of Rural England and Wales and the Friends of the Lake District, in a statement on the order concerning Ennerdale Water, which comes inside the Lake District national park, has indicated the perfunctory treatment which public issues may receive at the hands of a department, and the way in which the technical factors may be disregarded. The fate of Ennerdale at the hands of the Minister of Health indicates how slender are the prospects for national parks anywhere if the Ministry of Town and Country Planning remains merely one among several departments with no overriding powers.

The same point is made in a statement on Services training areas which has since been issued by the Standing Committee on National Parks. While the statement is chiefly concerned to direct attention to the necessity for protecting potential national park areas from any form of development inconsistent with their ultimate use when the necessary legislation is secured, it is of interest here as indicating the limitations of the method of handling the claims of the Services piecemeal before the Inter-Departmental Committee. That Committee can do no more than consider each case in isolation as it comes before it, and report to a committee of the Cabinet on unresolved claims. There is no provision for the consideration of the claims as a whole, still less of the possibilities of co-ordinating and combining claims of different Services and commands and establishing principles by which individual cases can be decided; nor, more important still, for examining the allocation of the total land resources of the country to agriculture, industry, military training, electric power and water supply and popular enjoyment. If that is too large a question to be entrusted to an individual Ministry such as that of Town and Country Planning, it might well be examined by a Select Committee of both Houses of Parliament, as the National Parks Committee recommends. The imperative need for some such body with powers to enforce decisions even on recalcitrant Government departments could scarcely be better illustrated than by the decision of the War Office to retain 238 acres of London's 'green belt' near Coulsdon and Purley for a bombing range. The most perfunctory study of the Land Utilization Survey's map of Great Britain, or of the admirable population maps published for the Ministry of Town and Country Planning, should convince anyone of the need for reconsideration of such proposals.

One of the biggest questions is, in fact, whether the Bill as at present drafted provides machinery of national planning powerful enough to withstand an interested department. The decision should clearly not rest, for example, on whether the capacity of the War Office for passive resistance is stronger than the political importance of London local authorities; it should depend on an unbiased consideration of the best use of the nation's land, and proper safeguards to that end should be provided. It is disturbing to note that Mr. H. D. Hughes's specific question on this point in the debate in the House of Commons on the second reading of the Bill was unanswered when the Chancellor of the Exchequer wound up for the Government.

The incorporation of such over-riding and co-ordinating powers would, however, enhance the importance of the factor on which the efficacy of the whole Act will finally depend—the wisdom with which the control embodied in the Act is exercised. It was well said in the debate, by Mr. J. H. Hare, that the success or failure of the Bill, as it stands, must depend very largely on the wisdom, the integrity and the intelligence of those who are required to administer it. That is the point of most vital interest to the individual citizen, and the answer depends primarily on the quality of the administrator to whom the exercise of the new powers is entrusted. This is an issue transcending all party divisions. Agreed decisions on the financial provisions and on other procedure will not enable the Act to achieve its purposes unless it is administered with wisdom, dispatch and restraint. Indeed, one important reason for welcoming and fostering co-operation in the preparation of schemes contemplated in the Bill is that it should also assist in the training of administrators for that work, and in embuing them with the imaginative insight and understanding of the needs of the public, its comfort and convenience, which it should be the first object of public administration to study and to serve.

MECHANISM OF COLOUR VISION

Retinal Structure and Colour Vision

A Restatement and an Hypothesis. By Dr. E. N. Willmer. Pp. xii + 231 + 4 plates. (Cambridge: At the University Press, 1946.) 21*s*. net.

THE organ of sight continues to challenge imagination and experimental initiative and so maintains its position as one of the most fascinating living structures in existence, and at the same time the source of so much of our most important knowledge about life and matter. The list of British men of science who have made notable contributions to this field is as impressive as that of any other country. It begins with Newton, whose ideas inspired Thomas Young (according to the latter's own words). Brewster, Maxwell, Dalton, Lord Rayleigh made discoveries which are classical. From our own period one need but mention Adrian's brilliant pioneer work on optic nerve impulses, Lythgoe's discovery of transient orange, Stiles' of the directional sensitivity of the retina, and Wright's analysis of the fundamental trichromatic response curves to realize that the tradition is being maintained.

The latest contribution comes from a Cambridge histologist, Dr. E. N. Willmer. It is right that histologists should add their word to the discussion, since physiology has now reached the point at which further advance in our knowledge about the function of the retina must contain new histological terms. There are the well-known receptors, the rods and the cones, which have long been on the stage, probably too long, when one considers that to the receptors is attached a true nervous centre, exceedingly complex, and certainly of fundamental importance for the interpretation of the world around us in terms of brightness discrimination, general light perception and colour. Nature's idea, to project a piece of the central nervous system on to the periphery and thus make it easily accessible to adequate, localized and controllable stimulation, is a hint meant to be taken.

Dr. Willmer approaches his theme in an unorthodox manner. He does not accept the idea, implicit in so much of modern psychophysical work in this field, that there are three kinds of cones, for the perception of red, green and blue colours. He thinks that the cones only are responsible for the long wave-lengths, whereas the green and the blue regions are transmitted by two kinds of rods. In the human fovea there is only the 'green' kind of rod, a day-rod, to which he attributes a sensitivity curve corresponding to the scotopic luminosity curve. This necessitates the further assumption that the 'green' day-rod contains visual purple in some less-adaptable or less-spurious form, since our scotopic luminosity curve is certainly determined by the photochemical properties of visual purple. The choice of ordinates for the response of the cone (the red receptor) has given him greater difficulties owing to the accumulation of physiological evidence on this point which he has felt bound to observe. He then proceeds to construct a colour chart with his rod- and cone-response curves, compares it with the C.I.E. chart and several other properties of colour vision: altogether a very ingenious, stimulating and, besides, entertaining account of what the mechanism would look like if it had the fundamental response curves which he attributes to it.

Unorthodoxy in this matter, if it is to serve any purpose, can only be of interest if the theory propounded is properly worked out so that one can perceive its merits, deficiencies and value as a stimulus. From this point of view Dr. Willmer's work deserves high praise. In assessing its value as a truthful account of the mechanism of colour vision one must examine separately its two fundamental propositions. The first states that the green and blue regions of the spectrum are perceived by rods. There is a great deal of electrophysiological evidence in favour of this view to which I would like to subscribe myself, in the form that there certainly is a very intimate connexion between rods and colour reception in the short wavelengths. There is also evidence for a great range of variation in the adaptability of the rods, day-rods and properly dark-adapting rods, the latter utilizing the full visual purple sensitivity. Conversely, an intimate connexion exists between cones and red-sensitivity. Willmer's second fundamental assumption consists in ascribing to the day-rods the visual purple distribution of sensitivity. For this view there is no evidence; in fact, such evidence as exists rather suggests that part of the visual purple under the influence of illumination splits into blue and green elementary colour bands with maxima to either side of its own maximum in 500 mμ. In animals, single fibres can be found which respond in this manner. The pure cone eye of the snake has its maximum green sensitivity around 520–530 mμ. The electrophysiological work on single fibres in animals gives a more detailed picture of the retinal mechanism of colour reception than work on man, in fact, several narrow bands; but the spectral loci of the integrated colour bands responsible for red, green and blue reception are in essential agreement with the loci of the fundamental response curves which Wright and his collaborators have been forced to accept as the most probable ones (see, for example, W. D. Wright, "Researches on Normal and Defective Colour Vision, Kimpton, London, 1946). The latter, of course, are averages.

Of Dr. Willmer's two assumptions the first one, therefore, seems to me of greater interest and destined to survive as a starting point for experimentation. Psychophysical work on vision and, in particular, on colour vision tends to be conservative in methods and problems. It scarcely ever aims at an understanding of retinal processes going beyond the simple scheme of response curves attributed to three types of cones. Dr. Willmer is performing a real service to his subject by demonstrating the need for taking up points of view which arise from a consideration of the histological structure of the retina and the physiological experiments directed towards interpreting it in functional terms. He is, for example, rightly concerned with the very fundamental problem as to what use the retina makes of its mechanisms of inhibition, what it signifies that in certain circumstances light does not elicit impulses at all but, on the contrary, stops them. If Dr. Willmer, in pursuing his subject, would turn his gifts of imagination and perseverance into experimental channels he would, no doubt, be able to suggest several interesting ways of studying rods and cones in relation to that little nervous centre placed at the end of the optic nerve just behind the layer of receptors. In view of a few very interesting experiments, found in his stimulating book, this would seem to be a safe forecast.

RAGNAR GRANIT

FROM AQUINAS TO EINSTEIN

Space and Spirit

Theories of the Universe and the Arguments for the Existence of God. By Sir Edmund Whittaker. Pp. vii + 150. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1946.) 6*s*. net.

SIR EDMUND WHITTAKER here gives the substance of his Donnellan Lectures delivered in June 1946 in Trinity College, Dublin; and the closing words of the book express its aim, namely, to indicate "that the deeper understanding of the nature of the material universe, which has been achieved by scientific discovery, has opened up new prospects and possibilities to the advocate of belief in God".

Sir Edmund holds that the line of descent of the modern physicist is from the Schoolmen of the twelfth and thirteenth centuries who translated into Latin the Arabic versions of Greek mathematics and science, and were Aristotelians, attaching meaning and value to the concrete things of sense and relying upon experience. Herein they were innovators and modernists, rejecting the Neoplatonist philosophy, dominant since Augustine, for which the material world of sense was the lowest and vilest element in the scheme of things. Aquinas' famous five proofs of the existence of God have their starting point in experience and are grounded in Nature.

Radical changes in physical theory have taken place since Aquinas elaborated his arguments, changes associated with the names of Copernicus, Kepler, Galileo, Descartes and Newton. Then in their turn the classical physical theories of Newton have been subjected to radical criticism and modification in view of the principles of relativity and of quantum-mechanics. Thus one might expect to find little that is relevant to-day in the Schoolmen's reasonings.

In one respect indeed their attitude differed from that which has been general since the Renaissance; they strove to understand the purpose behind events rather than to discover the laws of their operation. Yet the real difference is not so great as might appear, since to regard natural objects as striving to accomplish some purpose is only a naïve way of saying that their behaviour is not haphazard or lawless. Either formulation of the initial assumption would serve the purpose of Aquinas' argument. Indeed, it is in some respects reinforced by recent developments. For example, the ability of the mathematician to predict the existence of wholly new and unexpected phenomena in the external world reveals an order in Nature which transcends the range of experimental facts. Einstein's predictions of the bending of light-rays by the sun's attraction is a case in point. Again, recent researches have led to the conclusion that the universe cannot have existed for an infinite time in the past, at any rate under the laws of Nature as we know them. This re-introduces the idea of a creation, established by rational science, and not, as held to be the only possible way by Aquinas, by revelation. Moreover, the fact, unknown to Aquinas, that the *same* mathematical laws are valid over the cosmos, leads to the inference that there is only a *single* mind involved in the whole creation. In short, "the proof from Order is to-day more complete, more comprehensive, and more majestic than in the form in which it was presented in the thirteenth century".

Those who are interested in the bearing of modern physical theories upon ultimate problems will highly value this lucid and original book.

J. C. HARDWICK

ORIGINS OF WATER TRANSPORT

Water Transport

Origins and Early Evolution. By James Hornell. Pp. xv + 307 + 45 plates. (Cambridge: At the University Press, 1946.) 30*s*. net.

MR. HORNELL has accomplished a valuable work in preparing this account of how mankind conceived and made use of floating structures in order to traverse stretches of water. His research is confined to the evolutionary period down to the sailing ship; details of construction are reviewed and distribution in time and space recorded.

Relatively little is known of man's greatest achievements; his written history is but the history of yesterday, and the most significant advances—such as the development of speech—were prehistoric. If the source of European civilization can rightly be traced to certain amphibious tribes who dwelt on the coast of the Mediterranean, raising the piles of their houses in the water so to escape the greater perils of the land, then some kind of rudimentary navigation was the prime condition of human progress, and the importance of that development is transcendental. Mr. Hornell deals with primitive watercraft in three main groups: (*a*) floats, rafts and kindred craft; (*b*) skin boats: coracles, curraghs, kayaks and their kin; (*c*) bark canoes, dugouts and plank-built craft. Groups (*a*) and (*b*) have each five chapters covering the evolution; group (*c*) carries nine chapters and reflects to some extent the background of human aspiration—social, religious and economic—which was the cause of the technical development. Here the genetic relation of the bark canoe to dugouts and plank-built boats is considered, and the author, while re-stating his conviction that the boats of clinker and carvel build in use in Europe to-day are derived ultimately from the dugout canoe, observes that the genesis of many current types of dugout was the imitation in wood of the form of a canoe made from a sheet of bark. This implies that the origin of actual boat construction must be moved back much further in time, because the ancient forest people—regarded as the first 'human' ancestors—were restricted to the rudest of stone tools and yet, it is inferred, were capable of stripping the bark from trees, and by the use of a long strip curled up at each side, with the ends stopped by clay, were able to navigate the waters. The hypothesis derives support from the material culture of the Australian aborigines to-day, which can be little if at all advanced beyond that of our ancestral forest dwellers, and among whom all the relevant gradations in canoe design have been found. The possibility that dugouts evolved independently in some localities cannot be excluded, and, as the author remarks, the genetic relationship will probably remain an open question for all time.

Transition from the dugout to the carvel-built ship is more easily determined. The fashioning of the former was primarily a matter of patient labour, even when fire was used, but where large timber was available, the dugout might assume sea-going proportions. Increase in the freeboard of dugouts by the addition of a washstrake certainly marked the first stage, and in certain types the strakes—in the form of rows of superimposed planking—were sewn edge to edge and a strengthening frame was inserted. Bending of the sides outwards to obtain greater beam; insertion of wedged cross-bars to preserve the flare, and its continuation by a deep washstrake; and, finally, reduction of the underbody to the form of a keel member were further stages.

The historic differentiation between the techniques of carvel and clinker build is elucidated, and also the Mediterranean origin of the former. It is significant that all boats there and in the Indian Ocean are so built, whereas the clinker build is found only in the seas of north Europe. The determining of prototypes is here obscure: that the latter should have derived from a raft with built-up sides seems credible; but rafts were not used in the bleak northern seas, and we must look to the dugout canoe as the precursor of clinker build, the essentials of which have persisted since Viking times.

In the final chapter, primitive belief in the need for intimate association between a protective god and watercraft is discussed—in particular, the prow of the ship as the sanctuary of its tutelary deity. This superstition takes the form of definite and often periodic worship, with suitable offerings, of a protective deity there located, and of traditional acts performed to ensure immunity from the effects of the evil eye—possibly the source of the Christian practice of blessing aeroplanes and other vehicles. Mr. Hornell observes that the rites are often intermingled and cannot therefore be considered separately; most of the instances he cites come within his own personal knowledge. Dedication, with elaborate ceremonies, of a vessel to a goddess who would abide in it, and be its protectress during voyage across the sea, is described; the final rite consisted of the incision of an eye on each bow—the ceremony of the 'opening of the eyes'. This 'cult of the oculus' is still widespread; originally it symbolized the deity's eyes watching for danger, but became debased to a mere amulet. The sacrificial ceremonies connected with launching, and the various rites associated with placating a deity when becalmed, are discussed from abundant data at the author's command. Out of this inquiry little emerges that is satisfying to the technical reader, but the association of the stemhead with such rites is interesting.

It is true, as the publishers say, that the book could not have been written without first-hand knowledge; and in this the author's qualifications are exceptional, for he has travelled all over the world and examined most of the craft he describes and observed their daily use. His investigation was thus carried out in a scientific manner; and when to this scholarship is added, the result cannot be other than illuminating. The book is profusely illustrated by photographs and text-figures and is extremely well documented. Recent distribution of eight categories of primitive craft is shown on Mercator's projection.

M. J. B. DAVY

Sun, Moon and Stars

Astronomy for Beginners. By Prof. William T. Skilling and Robert S. Richardson. (Whittlesey House Publication.) Pp. viii+274. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 12*s.* 6*d.*

THE authors of this book are well equipped for producing a work that will appeal to young people—and one might add to older people, too, who have little or no scientific background. Prof. Skilling has taught astronomy for many years and Dr. Richardson, at present associated with the Mount Wilson Observatory, has devoted a number of years to research. Five parts deal in turn with "The Moon", "The Sun", "The Sun's Family of Planets", "The Stars", and "Astronomers and Observatories", and the subjects are treated in a manner which requires practically no mathematics, or where such is introduced, it is of the most elementary character. The descriptions are excellent for the readers for whom the book is intended, and are illustrated by ninety-nine diagrams and photographs.

The work has been produced primarily for American readers, but it will probably have a good circulation among British readers as well. For this reason it is suggested that a new edition might contain certain amendments where the text is directed specifically to American readers and may mislead others (pp. 48, 109, 165).

A few other points require attention. The reference to the rising of the full moon in September (p. 37) does not apply for all latitudes; and the old theory about the apparent enlargement of the moon when close to the horizon (p. 42) is no longer held. The corona can now be seen without a total solar eclipse (p. 87). It might be inferred (p. 107) that the tidal theory of the origin of the solar system is generally accepted, but it would be more correct to say that it was generally rejected; and the view that swift meteors are hyperbolic (p. 164) is no longer held. These are very minor blemishes which do not detract from the value of a most readable and informative book. M. Davidson

Exploring Nature with a Camera

By Ernest G. Neal. Pp. 103+62 plates. (London: Paul Elek (Publishers), Ltd., 1946.) 10*s.* 6*d.* net.

BIRD photography has reached such a pitch of excellence, its devotees are so many and so enthusiastic, that we are apt to forget that the camera is a useful aid in many other branches of field work. In "Exploring Nature with a Camera", Mr. E. G. Neal makes this clear. He deals, it is true, with the photography of birds, but he devotes as much or more space to insect photography, night photography, plant photography and so on. His chapter on night work is illustrated by some good flashlight pictures of badgers near their sett, and we envy him the thrill of taking them. The author says in his preface that "this book is written in the hope that the keen naturalist who has got a camera, especially those of the younger generation, will be encouraged to try it out", and it can be highly recommended as a present for the beginner. Although Mr. Neal says his little volume "is not a technical book on photography", it is full of practical information on the use of the camera (not forgetting his hints on the type of instrument) and how to take pictures of birds, mammals, insects, reptiles, flowers, fungi, etc. Here and there, as if by accident, interesting observations are recorded. Commenting that it is often easier to photograph a portion of an object than the whole, say a few twigs rather than the whole tree, he gives as an instance ice-encased twigs during the great 'crystal thaw' of 1939–40, when trees, bushes and other vegetation were thickly coated with clear ice. Then, as an aside, he remarks, "I was interested to see a wych elm tree with the usual covering of ice, for I knew that the white letter hairstreak butterfly (*Strymon w-album*) laid its eggs every year on the twigs of this particular tree, and that they would now be encased in ice. The following July this species was more common than for many years, so the ice had no appreciable bad effect."

Frances Pitt

Insects of the Pacific World

By C. H. Curran. (Pacific World Series.) Pp. xvi+317+8 plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1945.) 15*s.* net.

THIS book is intended as an elementary guide to the insect life on the numerous islands, large and small, of the Pacific Ocean—"from the Galapagos and Hawaii to New Zealand, Sumatra and Burma, and in the area from Australia to Formosa, Japan and the Aleutians". It is a plain, readable account, taking the insects of each order, family by family. Beginning with the true flies, it passes in descending sequence to the Orthoptera and Apterygota. At the end of the book there are brief chapters on the Arachnida and their allies (by W. J. Gertsch), on insects and disease and, finally, instructions on preserving and collecting insects. For the most part the book deals with its subject in very general terms, and says singularly little about individual Pacific insects. Even the well-known elements in the fauna of Hawaii and New Guinea scarcely receive mention. But, as the author remarks, what chance is there to say much about so many insects of which so little is known. The size of the book, indeed, limits the treatment severely. The text-figures and plates are good and, apart from misspellings on pp. 13, 140 and 141, and an erroneous account of *Cactoblastis* on p. 149, the book will aid the beginner who may visit the vast area under consideration. A. D. I.

Esquisse d'une histoire de la biologie

Par Jean Rostand. Pp. 258+14 plates. (Paris: Libr. Gallimard, 1945.) 140 francs.

THIS sketch summarizes the history of biology from the middle of the seventeenth century up to the present day, the term biology being used in a restricted sense to include only the fundamental problems of organic life, namely, the genesis of life; the formation of the organism; and the evolution of species. While the overall treatment of the subject is chronological, its detailed development is traced in relation to the men of science responsible for major advances. The following examples, selected from the twenty-three chapter headings, suffice to indicate the scope and treatment: Redi, Leeuwenhoek and the microscope; the experiments of Lazaro Spallanzani; Cuvier and the science of fossils; Charles Darwin and the origin of species; recent advances in biology. Short biographies of the naturalists who have made major contributions to biological thought are included in the chapters dealing with their work. The book concludes with a table setting out the principal dates in the history of biology, a brief bibliography and an index of names cited. It should serve as a valuable introduction to the subject for university students in biology.

ATOMIC ENERGY AND ITS APPLICATIONS*

By SIR JAMES CHADWICK, F.R.S.

THE fission process can be briefly described as follows. A neutron is captured by a nucleus of uranium 235, forming a nucleus of uranium 236 in a highly excited state. This immediately divides into two fragments of roughly equal mass, and at the same time from one to three neutrons are emitted (and also some γ-radiation). The fragments fly apart with considerable speed and, in their passage through matter, their energy of motion is finally transformed into heat. These fragments are, in general, unstable and may pass through a series of transformations, emitting β-particles and γ-radiations, before they reach a stable configuration.

It was immediately recognized that this discovery was of the greatest significance and that it opened up the possibility of a practical utilization of the enormous store of atomic energy. Not only did the fission of uranium release a large amount of energy, but also the emission of more than one new neutron each time that a nucleus suffered fission suggested the possibility that the reaction could be propagated from atom to atom, developing a whole chain of reactions from one single event. Such a chain process developing in a mass of uranium might take place at an ever-increasing rate and might involve so many atoms that there would be an appreciable, and possibly an overwhelming, liberation of energy. In this way it seemed that a new type of combustion of matter might be possible which would give an energy yield a million times greater than that obtainable by the combustion of the same weight of coal or oil.

A chain reaction will not necessarily develop in any piece of fissile material. Certain conditions must be satisfied. In the first place, the amount of fissile material, or the reacting system as a whole, must be of such a size that there is not too great a chance that the neutrons produced in the fission process can escape and so be unable to carry on the chain. Secondly, the system must not contain more than a limited amount of material which absorbs neutrons, for in this way again the neutrons will be prevented from continuing the chain reaction.

If these conditions are satisfied, the chain reaction will develop and 'run away', unless some special device is introduced to control it. Thus we have two general types of chain reaction—the uncontrolled reaction and the controlled reaction.

Uncontrolled Reaction: the Atomic Bomb

If we wish to use atomic energy as an explosive the reaction must be uncontrolled, for the more rapidly it can proceed, the greater will be the amount of energy set free and the explosive effect.

The question of size is critical for an atomic explosion, for a chain reaction cannot develop if the mass of fissile material is too small. This is because the reaction depends on the conservation of the neutrons produced in the fissions. If the piece of material is too small or of an unsuitable shape, too many neutrons will escape before they hit a nucleus and propagate the reaction. The proportion of neutrons which escape can be reduced by increasing the size of the piece, since the production of neutrons is a volume effect and will therefore increase more rapidly with size than the loss of neutrons by escape, which is a surface effect. Thus a certain minimum amount of material is required, called the critical size or amount, before the reaction can develop so fully that an explosion occurs. If the piece of fissile material is less than the critical size it will be quite stable; but as soon as it exceeds this a chain reaction will develop and multiply itself with enormous rapidity. Thus all that is necessary to detonate a bomb of uranium 235 is to bring together two pieces each less than the critical size but which when in contact exceed it.

Suppose we have succeeded in doing this by some means, and that at the same moment we shoot a neutron into the material. This will cause fission of one uranium nucleus and produce, let us say, two fission neutrons which in turn produce four, and so on in successive generations. Since the fission neutrons have speeds of the order of 10^9 cm. per sec., and since they do not have to travel many centimetres before they produce new fissions, the time between successive generations, in which the number of neutrons is doubled, is of the order of 10^{-8} sec. In a millionth of a second, therefore, the number of neutrons will have increased enormously and a considerable fraction of the mass of U235 will have undergone fission. If only 1 kgm. is used up in this way, the amount of energy released will be as much as from 17,000 tons of T.N.T. This amount of energy is so great that the mass will attain a temperature of many million degrees and a pressure of many million atmospheres. The high temperature causes the emission of an enormous amount of heat and light, and the sudden expansion of the hot gases produces the shock wave of the explosion.

As the material expands, the neutrons can escape more easily and the reaction stops. By this time the hot glowing gases may have expanded to a diameter of about a third of a mile.

In addition to the blast wave and the intense heat and light from the hot gases, the atomic bomb emits an enormous radiation of gamma rays and neutrons at the moment of explosion. Further, the products formed by the fission process are intensely radioactive, and the total amount formed in the explosion may correspond in activity to many tons of radium.

Control of the Chain Reaction

In order to use atomic energy for industrial purposes, it is obviously necessary to control the chain reaction so that the energy can be released continuously and at a predetermined rate. It seems at first sight that the control of a reaction which can develop so rapidly and which can liberate such enormous energies must be exceedingly difficult. This is, fortunately, not the case, and in practice the control is remarkably simple, effective and accurate.

Control depends on the regulation of the neutron flux so that at a predetermined level the flux remains constant, only exactly as many neutrons causing fission in one generation as in the previous generation. The extra neutrons which are produced in the fissions are removed and made unavailable for the reaction. The reaction will then proceed at a constant rate. This balance can be achieved either: (1) by allowing the excess neutrons to escape from the system; or (2) by capturing them in some absorbing medium.

---

* From the Melchett Lecture of the Institute of Fuel delivered on October 8. The full lecture is published in the *Journal of the Institute of Fuel*, Dec. 15, 1946.

It will be convenient at this point to define a quantity called the multiplication or reproduction factor. Let us suppose that in a system containing fissile material there is a certain number, P, of free neutrons present at a given time. Some of these neutrons will initiate fissions and thus directly produce new neutrons, Q in number. The ratio Q/P is called the multiplication factor and denoted by k.

If k is less than 1, no chain reaction can develop. Any stray neutrons may produce a fission, but the chain will die away quickly and the system will be perfectly safe. This corresponds to a system which contains less than the critical amount of fissile material.

If k is greater than 1, as in the example quoted above for the atomic bomb, the number of neutrons will increase rapidly from generation to generation and an explosion will occur.

When k is exactly equal to 1, the reaction will proceed at a constant rate and the flux of neutrons will remain constant. This is the condition which has to be achieved for successful application of the chain reaction to general purposes.

The principle of the control of a chain reactor can be illustrated by a simple example. Let us suppose that we have two masses, A and B, of fissile material, each less than the critical amount but together considerably greater than it, and let us consider what happens as A and B are brought closer together.

When A and B are far apart, the leakage of neutrons will be great and the multiplication factor k will be less than 1. Suppose that at some stage in the approach k becomes equal to 0·99 and that we have in the material a source of neutrons which emits 1 neutron per second. This one neutron will produce k neutrons in the first generation, these k will produce k^2, and so on, so that the total number of neutrons being produced per second will be :

$$1 + k + k^2 + k^3 \ldots = \frac{1}{1-k}$$

if k is less than 1.

Thus when $k = 0{\cdot}99$ there will be 100 neutrons produced per second in the material, and the primary source has been multiplied 100 times. As the two parts are brought closer and closer together the leakage of neutrons diminishes, k becomes correspondingly nearer and nearer to 1, and the neutron intensity can be brought to any desired value.

It is evident, however, that an exceedingly fine adjustment of k will be required to reach a high intensity, so fine as to be impossible as a practical operation.

Let us now suppose that the two parts are close enough to make k slightly greater than 1. A divergent chain reaction will now develop and the neutron intensity will rise rapidly, doubling itself in each successive interval of time T given by the formula

$$T = 0{\cdot}7 \, \frac{\tau}{k-1},$$

where τ is the average life-time of one generation of neutrons.

Thus by making k slightly greater than 1 we could raise the level of neutron intensity very rapidly and, having reached the level it is desired to have in our reactor, we could now reduce k to 1 so that the desired level would be maintained.

While this adjustment is simple in principle, the possibility of carrying it out depends very much on the value of τ. Now the fission neutrons are emitted with velocities of the order of 10^9 cm. per sec., so that if they were all emitted instantaneously upon fission the value of τ would be of the order of 10^{-8} sec. But in order to allow time for the adjustment of the mechanisms which control the positions of A and B, we need a doubling time T of the order of a second ; and this would entail an adjustment of the value of k to less than one hundred-millionth part of its value. Even if this could be achieved, there would always be the danger of a slight temperature change or mechanical disturbance which might cause the neutron intensity to rise at an uncontrollable rate and result in a violent explosion.

If the picture I have given were quite accurate, the control of the chain reaction would evidently be a formidable operation. Fortunately, however, not quite all the neutrons are emitted instantaneously upon fission. Some of the fission products transform after a time with the emission of a β-particle into nuclei which are now unstable and emit neutrons.

We have, therefore, in addition to the prompt neutrons released in the fission process itself some neutrons which are delayed after the fission by the time required for the transformation of the fission fragments. The effect of these delayed neutrons is to increase the average time for neutron generation and, therefore, to reduce the rate at which the chain reaction develops.

The importance of this effect can be shown by a simple calculation.

For the purpose of this calculation we may assume that the delayed neutrons form 1 per cent of the total neutron emission from fission and that the average time of delay is 10 sec. We now arrange the assembly of fissile material so that it is only just above the critical condition, with a multiplication factor k greater than 1 but less than 1·01. This means that the prompt neutrons alone will be insufficient to maintain the chain reaction and each generation of neutrons will have to wait for the delayed neutron emission before a divergent increase in intensity can occur. The neutron intensity will double itself for each interval of time T given by

$$T = 0{\cdot}7 \cdot \frac{1-k_p}{k-1} \quad \tau_D,$$

where k_p is the multiplication factor due to the prompt neutrons alone, and τ_D is the average time between the fission and the emission of the delayed neutrons, that is, 10 sec.

If we put $k = 1{\cdot}005$, then k_p will be about 0·995, and the doubling time is about 7 sec.

Thus, provided the assembly is only a small degree above the critical size, the effect of the delayed neutron emission is to make the reaction grow quite slowly. It will therefore be easy to control the reaction and to hold the level of the reaction and the neutron intensity at any desired level. The adjustment of the neutron leakage may be a simple type of mechanical control which moves a small part of the reactor relative to the main system or which moves reflectors which can reflect back into the system some of the neutrons which would otherwise escape. In this way, the reaction can be controlled smoothly and the level of the reaction can be held very steady ; in fact, in some of the so-called 'slow reactors', the level can be held to better than one part in 10,000 over long periods of time.

Fast and Slow Neutron Reactors

The systems I have so far considered are known as fast neutron reactors, because the chain reaction is carried on by the fission neutrons without moderation of their speed except that which inevitably must occur in collisions in the system, whether in the fissile material itself or in parts of the apparatus for assembly, etc., and these neutrons have velocities of the order of 10^9 cm. per sec.

Slow neutrons, however, are much more effective in producing fission both in U235 and in plutonium than are fast neutrons. Thus, if the fission neutrons could be slowed down before reproducing themselves, the chain reaction could be maintained in a smaller amount of fissile material, or even in much less pure material than is required for the fast reactor.

One advantage of the slow neutron reactor is the simplicity of control. Some substances, notably boron and cadmium, absorb slow neutrons very strongly. This fact provides a very ready method of controlling the reaction, by moving rods of these materials in or out of the reactor and so adjusting the multiplication factor by changing the loss of neutrons by absorption rather than by changing the loss by leakage as in the fast reactor. It is obvious that a simple mechanical device will suffice to carry out this control.

A very important advantage offered by the use of slow neutrons is that it is no longer necessary to use pure or nearly pure fissile material in order that the chain reaction should maintain itself. In fact, as is well known, it is possible to use natural uranium, thus avoiding the very expensive and tedious process of separating the isotopes.

In this case, owing to the fact that the 238 isotope captures neutrons without undergoing fission and that this isotope is 139 times as abundant as the fissile 235, the choice of material for slowing down the neutrons is rather limited, for very little additional loss of neutrons can be tolerated. For this reason it has not been found possible to use water as moderator, for hydrogen captures slow neutrons too readily. Heavy water makes a very suitable moderator, for the capture by deuterium is small, and it has been successfully used in the United States and later in Canada. It is, however, too expensive a substance to use for large reactors.

The best material readily available at the present time is carbon, in the form of graphite. This has the advantage of being relatively cheap and abundant, and it can be obtained in a very pure state.

Owing to the inevitable, though small, loss of neutrons by absorption in the graphite, the multiplication factor of a uranium-graphite system is not much greater than 1. The critical size of the reactor is, therefore, rather large, and some tons of uranium and of graphite are required. The construction of a reactor of small power is a straightforward matter, but difficulties arise when large power dissipation is desired, of the order, say, of 100,000 kW., owing to the small latitude in the multiplication factor. The nature of these difficulties will be best illustrated by a brief description of the large reactors, the so-called graphite piles, erected at Hanford, although the primary purpose of these piles was the production of plutonium rather than the generation of power.

Natural Uranium Reactor—the Graphite Pile

For reasons depending on the nuclear properties of uranium, the arrangement which gives the highest multiplication factor is one in which lumps of metallic uranium are disposed at regular intervals throughout a large block of graphite in the form of a lattice. The ideal shape would be spherical, but for practical considerations a rectangular block is used. The optimum size of the uranium lumps and of the lattice spacing can be calculated from the nuclear constants of the materials. This was the arrangement used in the first graphite pile of very low power, but it had to be modified for the plutonium production pile. There were two reasons: first, the uranium has to be cooled in order to remove the heat generated by fission, and it is difficult to concentrate the coolant at small lumps, and second, it was required to remove the uranium without disturbing the assembly of the pile.

The arrangement used in the Hanford piles is, therefore, a rod lattice of cylindrical symmetry, in which short rods or slugs of uranium are loaded in cylindrical channels in the graphite moderator. This entails some reduction in the multiplication factor.

The cooling agent, water in this case, is circulated through pipes around the rods. Since graphite pipes are not practical, on engineering grounds, some other material has to be used, and the choice is limited by the condition that the material must have a small absorption for neutrons. The material chosen was aluminium.

Further, the uranium must be protected from the cooling water, for it is easily oxidized, and even if the slugs were not disintegrated by chemical action, sufficient fission products would enter the cooling water to make operation dangerous. The protective jacket must have a high conductivity in order to transmit heat quickly from the uranium to the water, it must not absorb too many neutrons, and it must not corrode. Aluminium fulfils these conditions fairly well.

The introduction of this auxiliary material in the form of cooling pipes, sheathing, instruments, etc., increases the loss of neutrons by absorption, and it is, therefore, necessary to keep down the loss by leakage to a few per cent. This is not difficult, for the leakage can obviously be made as small as desired by making the reacting system sufficiently large.

The problem of dissipating some 100,000 kW. or so is not difficult provided an ample supply of pure water is available, but it is complicated by factors peculiar to an atomic energy reactor. In its passage through the pile, the water becomes radioactive, so that if the water is to be returned to a river a retention basin must be provided to ensure a delay, during which the induced radioactivity dies down to a safe level. Further, the circulating system must be very reliable, and fast-operating controls must be provided in order to shut down the chain reaction quickly in case of failure of the water supply.

The control is essentially no more difficult than for a small slow reactor, but, of course, the large reactor is potentially much more dangerous. The operating controls, connected with instruments in the pile, which measure the neutron density and thus the power level, can automatically keep the pile operating at a predetermined level. In addition, emergency controls are provided to operate as soon as the power level shows signs of undue increase.

The radiation from a pile operating even at low power is strong enough to be dangerous to human life, and that from a high-power pile reaches a fantastic intensity. The whole of the reacting unit must, therefore, be enclosed in steel and thick walls of concrete, and it must be possible to load and unload the pile through these shields. Any operation on the pile must be carried out by remote control.

The design and operation of the Hanford piles was thus beset by difficulties, many of them new and peculiar to an atomic energy plant, but they have operated for nearly two years without trouble at a power level of perhaps a few hundred thousand kilowatts.

The total weight of a pile, including the massive shielding, amounts to some thousands of tons, but it is, nevertheless, a very compact unit for the amount of power which is generated in it.

Production of Useful Power

The energy generated in the Hanford piles is removed by the cooling water which issues at a temperature considerably below 100° C.—too low a temperature for efficient conversion of the heat to useful power. If such a pile is to have general industrial applications, such as the generation of steam and the generation of electric power, it must be run at a much higher temperature. To do this will necessitate considerable changes in design and in operating technique.

It would probably be possible to use liquid bismuth as coolant instead of water, and it might be an advantage to use some other material than graphite as moderator. Progress on these lines demands the solution of some awkward engineering and metallurgical problems; but there is no reason to suppose that the difficulties cannot be overcome.

The most striking characteristics of atomic energy reactors are their compactness for large power capacity and their ability to run for long periods with little or no refuelling.

The power available from an atomic energy reactor is limited essentially only by the rate at which the heat can be removed from it, so that a million-kW. plant need be no bigger than a normal electric power sub-station.

The energy released in the combustion by fission of 1 lb. of U235 or plutonium is rather more than 11 million kWh., equal to the amount of energy which can be obtained from about 1,500 tons of coal or 250,000 gallons of fuel oil. Thus an atomic energy unit may be able to run for long periods on one charge of fuel, and the cost of transport of fuel will, in any event, be small.

Moreover, the plant may, under appropriate conditions, be able to regenerate some, if not all, of its fuel. This arises from the possibility of designing the plant so that some of the neutrons released in fission are used to produce plutonium in uranium, disposed in a suitable way inside or outside the reactor, which will replace the U235 or plutonium which is burned.

This process of replacement takes place in the Hanford piles, where U235 is indirectly converted into plutonium. It may be possible under some conditions to arrange that as uranium 235 is burned the reaction could continue by burning the plutonium, and in this way most of the uranium 238 as well as the 235 might be utilized.

This relative freedom from supply problems, once the plant is set up, opens up the possibility of stimulating industrial development in isolated parts of the world, where coal- or water-power are not readily available. For the same reason, it might prove advantageous to establish atomic energy units in close proximity to mines, more especially in those cases where the ores have to be transported long distances in their crude states.

They may also find application in large ocean-going vessels, in cases where it is desired to avoid frequent refuelling. This application is somewhat more questionable on account of some aspects of atomic reactors, to which I shall refer later.

We must not forget, however, that these bright prospects for the peaceful applications of atomic energy depend on the solution of difficult engineering problems, and that no reactor has yet been developed, or, I believe, even designed, which is suitable for the purposes I have mentioned. Nor must we forget the limitations and disadvantages to which the atomic energy unit is subject, and which are inherent to it.

One of the most serious disadvantages from the point of view of general industrial use arises from the fact that an atomic energy reactor is a source of very intense and very dangerous radiations. A reactor operating at a power level of 1 watt produces as many γ-rays as a few grams of radium (without the radiations from the fission products) and some neutron radiation as well. Although a considerable fraction of these radiations will be absorbed in the reactor itself, shielding is required in order to protect personnel in the vicinity. Even in the case of a very compact unit, the weight of shielding will be considerable.

For example, let us take the case of a reactor dissipating (not generating as useful energy) 100,000 kW. This cannot be much less in size than a 1-metre cube, having regard to the difficulty of the problems of heat transfer. It is easy to show that the weight of the shielding required to reduce the radiations from this unit to a safe level would be a few hundred tons. Even a low-power reactor will need shielding at least 50 to 100 tons in weight, and this factor alone prohibits the application of this type of power to motor-cars or any small mobile units.

Another limitation in the application of atomic energy is that a relatively large amount of fissile material is required even for a low-power unit. This arises from the fact that a 'critical size' is necessary before the chain reaction can develop. Thus, for some time to come, the minimum cost of materials for a power unit may be many thousands of pounds, and it becomes uneconomic to use atomic energy for small plants.

Another consideration is that practically every material which is incorporated in the construction of an atomic reactor becomes radioactive owing to its exposure to neutrons. For this reason, special provisions would have to be devised for maintenance.

The intense γ- and neutron-radiations also have an effect on the structural properties of the materials entering into the construction of the reactor. Owing to their ionizing properties, these radiations destroy the molecular bonds of many molecules. The choice of substances which can be used is, therefore, restricted to those which tend to return to their original state after intense ionization, such substances as elements and simple ionic compounds. How far even these will endure the very great irradiations resulting from large power outputs is not known, for experience is still very meagre. This effect may possibly set a limit to the power output of an atomic reactor and even to its life.

A further difficulty may be caused by the fission products, more especially in the case of the natural uranium reactor. Some of these fission products may absorb neutrons so strongly that after some time the chain reaction will be inhibited. In such a case, it would be necessary to remove the uranium, extract the fission products, and either to recharge the reactor with new metal or to recover the uranium and to replace it, adding sufficient plutonium or U235 to make it reactive.

Of necessity, all reactors manufacture fission products. At some stage or other, it will ultimately be desirable to remove them. Their disposal may prove to be an awkward problem.

Cost of Power Derived from Atomic Energy

So far as the *immediate* future is concerned, the application of atomic energy to the production of power is not likely to result in a net decrease of over-all costs to the community.

Owing to the difficult and tedious nature of the processes for preparing U235 or plutonium in high concentration, reactors depending on such materials for fuel will be far more costly to run than existing hydro-electric or steam-power plants, and the most favourable comparison at the present time will be given by the natural uranium reactor.

Recently an American committee has made a careful study of the costs of building and operating a natural uranium reactor to deliver 75,000 kW., and has concluded that the over-all cost of power would be only about 25 per cent greater than for a coal-burning power plant. This estimate is based on the assumption of a high operating temperature of the uranium reactor, that is, on the performance of a plant which has not even been designed, let alone built. It does not, therefore, represent the present position, but the possible position in a few years time, when research and development have provided the solution of a number of difficult technical problems. The committee's estimate is nevertheless valuable in indicating the possibilities which can already be foreseen. It is not unreasonable to expect that future development of atomic energy will result in a material reduction of costs, and perhaps make the uranium reactor a direct competitor with other power plants.

At the present moment it seems that the use of atomic power plants would be justified, on a purely economic basis, only in the special circumstances I have previously mentioned, where the power needed to develop resources is either very costly or unavailable, or because of difficulties of transport.

What is needed now is intensive research and development in the technical problems which are involved in the applications of atomic energy. This will not only clarify our present somewhat vague ideas, but it may well be that quite new lines may be opened up.

The Future

In assessing the possibilities of future development it is well to remember not only that the art is in its infancy, but also that the preoccupation of the war years with the military aspects of atomic energy has excluded almost completely the consideration of industrial applications. These military aspects still have, and, until some far-reaching international agreement on the control of such weapons is obtained, are bound to have, a retarding influence on peaceful developments, for the reason that the paramount need for security prevents that wide dissemination of knowledge which promotes free exchange of thought, stimulates discovery, and gives an impetus to invention and development.

At this early stage in our knowledge of these matters one cannot hope to see clearly into the future, but only to discern the probable lines of progress. Upon further investigation some lines we now have in mind may prove fruitless, but if we can be guided by the history of scientific and technical development, it is more than likely that others will give a rich reward. A few short years ago what has even now been accomplished would have been considered an idle dream.

Already a military weapon of unparalleled power has been created; enormous amounts of radioactive material have been manufactured; substances which have, owing to their inherent instability, become very rare or even completely disappeared from the cupboard of Nature, have been built up by individual nuclear transmutations and collected in large quantities; and the first steps have been taken towards the development of these new energy sources for industrial application.

This new enterprise constitutes a far deeper interference with the natural course of events than anything which has been attempted hitherto, and it is a most remarkable example of the powers of physical science and engineering and of our increasing control over the processes of Nature. It is not easy at this early stage to survey in detail the consequences which may flow from this advance in the years to come, but it can scarcely fail in the long run to bring about a new outlook and a new situation as regards human resources.

DR. JAMES HUTTON AND THE MANUFACTURE OF SAL AMMONIAC

By ARCHIBALD CLOW and NAN L. CLOW

THE hundred and fiftieth anniversary of the death of Dr. James Hutton (1726–97), the celebrated geologist, which occurred on March 26, brings to mind a little-known phase in the utilization of the products of coal distillation, the profits from which are said to have secured to Hutton the leisure necessary for his geological speculations.

In his "History of Inventions and Discoveries", J. Beckmann says: "If I am not mistaken, the first manufactories of sal ammoniac were established in Scotland: the oldest of these, perhaps, was that erected by Dovin and Hutton at Edinburgh in 1756"[1].

This refers to a co-partnership formed by Dr. James Hutton and someone variously described as James Dovin, Dairy, or Davie, in Edinburgh according to a plan conceived when they were Edinburgh students. In Kay's "Portraits"[2], the date of formation is given as before 1749, which may be right, since Hutton went to a Norfolk farm to study agricultural methods in 1752.

The raw material used in this early chemical manufacture was soot, and for a number of years Davie took all the soot collected by Edinburgh 'tronmen'—a chimney sweeps' society formed in 1738[3]. The process was carried out as follows: "Globular glass vessels, about a foot in diameter, are filled to within a few inches of their mouth with it [soot], and are then arranged in an oblong furnace, where they are exposed to a heat gradually increased. The upper part of the glass balloon stands out of the furnace, and is kept relatively cool by the air. On cooling, the upper parts of the globes are found to be lined with sal ammoniac in hemispherical lumps, about 2·5 inches thick. 26 lbs. of soot yield 6 of sal ammoniac."

There is a reference to the manufacture of sal ammoniac in Edinburgh, and to green glass globes used in the manufacture, in a letter from John Findlay, secretary to the Duke of Richmond, to George Macintosh, the Cudbear and Turkey red manufacturer, and it seems probable that the vessels used by Hutton and Davie were old vitriol bottles from the Prestonpans Vitriol Works, founded by Dr. John Roebuck and Samuel Garbett in 1749[4].

The firm of Hutton and Davie was still in existence in 1783, and in that year they began buying sal ammoniac, probably crude, from the tar works established at Culross in 1781 by Archibald Cochrane, ninth Earl of Dundonald.

Dundonald's sal ammoniac was one of the by-products of his tar manufactory. The preliminaries in the negotiations for the sale of the sal ammoniac to Hutton and Davie are referred to in the report that Dr. Joseph Black, professor of chemistry in Edinburgh, prepared for Andrew Stuart, when the latter was trying to ascertain the likely success that might attend the founding of the British Tar Co. After going into the details of prospective profits from the sale of tar and coke, Dr. Black goes on : "There is one article omitted above, which is a quantity of Volatile Alkali formed in the water condensed along with the tar from the vapour of the coals. The volatile alkali, after being somewhat refined from the oil and water can be employed in the manufacture of sal ammoniac : and My Lord having sent a specimen of his prepared or purified alkali to Messrs. Hutton and Davie who manufacture sal ammoniac here, I know that they found it good for the purpose and made his Lordship an offer for a certain quantity annually, the consumption of sal ammoniac being limited. But I do not know what offer they have made, or what profit this article is capable of yielding. They have hitherto extracted their volatile alkali from soot, which is also produced by the condensation of vapour from coals"[5].

Evidently Lord Dundonald hoped to make a considerable business by working up this side-line, because he wrote Andrew Stuart, his uncle : "My partners and I have it in our Power to render him [Glassford]* very essential service by purchasing from him annually some Thousand Pounds worth of a commodity he manufactures concerning which I shall explain myself more fully when I have the pleasure of seeing him in Scotland"[6].

The latter refers to the purchase of either sulphuric acid or hydrochloric acid, to be used in the manufacture of sal ammoniac.

Dundonald sent a William Kinnaird, chemist and apothecary, to London in 1784 to learn the best way of making sal ammoniac. Dundonald and his two brothers, John and Alexander, who were already his business associates in the British Tar Co., were to join Kinnaird in the manufacture ; but difficulties arose over Kinnaird's wages, and it is said that he did everything he could to sabotage Dundonald's enterprise because he wished to start on his own[7].

The method of manufacture employed by Dundonald was probably that invented by M. Leblanc of St. Denis, near Paris, with this difference, that Leblanc got his ammonia by the destructive distillation of organic matter, whereas Dundonald's ammonia was produced by the action of heat upon nitrogenous matter in coal. The ammonia was combined with hydrochloric acid, which was produced in a brick kiln by the action of sulphuric acid on the sea salt he could obtain from his own pans at Culross[8].

None the less, soot continued to be used as a raw material, both by Hutton and Davie, and also in a new manufactory which was founded by Charles Macintosh at Glasgow in 1786, in partnership with his father, George Macintosh, of the Cudbear and Turkey Red Works, and a Mr. William Couper, an eminent Glasgow surgeon.

The Macintosh factory continued for a number of years, but it is probable that more scientific methods of making sal ammoniac led to its being closed down[9]. In any event, by 1814, according to Sir John Sinclair, there was only one sal ammoniac works of any size in Scotland, and that was at Bo'ness[10]. There Joseph Astley operated a patent process similar to that referred to in the *Annales de Chimie* of 1797 (20, 186), which used 'bittern' from the salt works as a raw material. From this factory sal ammoniac was retailed at £9 10*s.* 10*d.* per cwt. Considerable details about Astley's process are given by Thomas Thomson in his supplement to the "Encyclopædia Britannica" :

"One process more deserves to be mentioned, on account of its ingenuity and simplicity. It is the invention of Mr. Astley, who has secured the exclusive privilege by a patent, and has a manufactory at Borrowstowness, on the Firth of Forth, and another at Portobello, near Edinburgh. He mixes together animal matter (chiefly woollen rags), and what in Scotland is called *spirit of salt.* It is the mother ley that remains after all the crystals of common salt that can be got have been separated from sea-water. It consists chiefly of muriate of magnesia. This mixture is burned in furnaces, and the produce received in small chambers placed over the furnaces. This produce contains abundance of sal ammoniac, which is obtained pure by sublimation. We conceive the theory of this process to be, that the carbonate of ammonia is formed by the combustion of the animal matter. This carbonate immediately decomposes the muriate of magnesia, and sal ammoniac sublimes. In principle, therefore, it does not differ from Baume's original process, though, in point of economy, it is probably greatly superior to it."

Hutton died in 1797, and Davie not long after. Following Davie's death, it appears that Edinburgh soot was sent to Walker's works at Beverley, Yorks, because we learn that Astley, who is described as an extensive chemical manufacturer in Portobello, was involved in a legal action in the Court of Session through one of his clerks inveigling two or three members of the Edinburgh Tronman's Society (chimney sweeps) into a public house and persuading them to sign an agreement on behalf of the Society to supply Astley with all the soot they collected instead of sending it to Yorkshire[11].

The next phase in the utilization of coal by-products is the well-known development of the gas industry in the first two decades of the nineteenth century. The new information which we have set forth concerning the prior utilization of coal by-products throws new light on the economic background of the gas industry. It also gives a new perspective to the growth of experimental chemistry during the latter half of the eighteenth century; and it is worth bearing in mind that when Joseph Priestley discovered ammonia, he was exploring the properties of a substance of established utility as a saleable by-product of coal.

NATURE OF VIRULENCE

THE term 'virulence' has sometimes in the past been regarded as an intrinsic property of an infecting agent; that such a view is not entirely in accord with our knowledge of natural and experimental infections was apparent from the discussion on the nature of virulence at the meeting of the Society for Microbiology held in London on December 20. As virulence can only be measured in terms of the effect on the host by a micro-organism, using that term in its widest sense, it is obvious that the interaction between the micro-organism and host by which we estimate virulence will depend on many variables affecting both participants. Much of the discussion related to these variables and their effect on virulence. A very wide field was covered, contributions on the virulence of bacteria, of fungi and of viruses for both plant and animal hosts and of the parasitic protozoa being made by various speakers. It was generally accepted that multiplication of an infecting agent in the body of the host does not alone determine virulence, and that the term 'virulence' necessarily implies structural or functional damage to the tissues of the host.

It is clear that the morphology and physiology of plants are so different from those of animals that virulence of phytopathogens involves mechanisms different from those concerned in virulence of micro-organisms for animals. This point was clearly illustrated by Mrs. Dagny Oxford in her discussion of bacterial virulence in plants; the bacteria virulent for plants, unlike most of the animal pathogens, are free-living, relatively resistant and simple in their nutritive requirements. As most of these species do not split cellulose, they depend for their entry into plant tissues on abrasions or wounds. There may be some correlation of virulence of phytopathogenic bacteria with the power to produce pectolytic enzymes, and in some instances cell-free filtrates of bacterial cultures produce reactions in the plant tissues similar to those caused by the living bacteria. Mrs. Oxford pointed out that the resistance of plants to bacterial infection is a function of the local tissue cells and does not depend on any humoral mechanism such as operates in the resistance of animals to invading bacteria.

Fungi are, however, more important disease-producing agents in plants than are bacteria, and Prof. E. Gäumann of Zurich made a most interesting contribution in this field to the symposium. The necessary attributes for virulence were discussed in relation to different types of pathogenic fungi, the part played by the host tissues being emphasized. The damage to plant tissue appears in the case of one fungus to be due to a polypeptide which destroys the semipermeability of the plasma boundary layer; but the power to produce this substance *in vitro* is not of itself sufficient to determine virulence. The power to penetrate the plant tissues by the production of certain enzymes and to withstand the reactions of the host tissues are also necessary. In plant infections due to more than one fungus (mixed infections), the resulting disease may be dependent on the interaction of the infecting fungi and may not be controlled by the most virulent strain.

In his discussion on the virulence of bacteria in animals, Dr. D. W. Henderson pointed out that it is difficult to induce parasitism in normally saprophytic bacteria, and that this lack of virulence is due in some instances, although perhaps not in all, to their lack of power to multiply in the living body. In general, toxicity is inversely proportional to the degree of tissue invasion by a pathogenic bacterium. The species of the animal host, its physiological state, and its genetic constitution may all influence the virulence of a bacterial infection. Other points mentioned by Dr. Henderson as bearing on virulence concerned aggressins, route of entry of a bacterium into the body, and the synergistic action of other bacteria. The importance of the last two factors was later referred to by Dr. C. H. Andrewes in relation to the virulence of viruses for animals.

That apparent increase of virulence in a parasitic micro-organism may in fact be due to lessened resistance of the host was exemplified by Dr. J. T. Duncan in his contribution on virulence of ringworm fungi in animals. These fungi are frequently highly parasitic and highly infectious but of low pathogenicity, and the host parasite equilibrium may remain undisturbed for years. On the other hand, some of the normally saprophytic fungi may become highly pathogenic, producing severe systemic disease; and in some of these fungi pathogenicity is associated with the property of dimorphism, the organism being capable of developing, in place of the complex mycelial saprophytic form, a simple form adapted for rapid reproduction and invasion in animal tissues. In the case of such fungi, as with some of the ringworm fungi when implanted on an unusual animal host, high pathogenicity may be associated with low infectivity.

The parasitic protozoa afford instructive examples of variations in the host parasite relationship in relation to virulence. Prof. H. E. Shortt illustrated the state of true symbiosis between certain protozoa and their vertebrate or invertebrate hosts, and from the symbionts and commensals went on to consider the parasitic protozoa. Some of these may multiply without producing disease, but this balanced parasitism might be readily upset. The mechanism by which disease is produced by pathogenic protozoa is not clearly understood; no true toxins are demonstrable, and in some cases disease is due to mechanical effects resulting from extreme proliferation of the parasites in particular cells or tissues; for example, certain trypanosomes in the reticulo-endothelial cells or muscle, and the malaria parasite in blood cells. Death of such highly parasitized hosts is frequently due to super-added infection with bacteria or other infecting agents. In the state of latent or chronic protozoal infection, it can be shown by transfer to fresh hosts, or by measures which lower the resistance of the chronically infected animal, that the protozoan has not lost its virulence. On the whole, it seems that for this class of micro-organism (as for the viruses and certain of the more parasitic bacteria) excessive virulence is a disadvantage to the parasite from the point of view of survival of the species, and virulence may represent the initial stages of association between the parasite and host, to be succeeded by commensalism or symbiosis.

The virulence of viruses for plants or animals must be considered only as a virus-host relationship, as the known viruses are essentially parasitic. Both Dr. Kenneth Smith and Dr. C. H. Andrewes stressed the variations in virulence manifested in virus-host associations according to variations artificially induced or arising naturally in the infecting virus, or depending on host factors and particularly on host species. The highly virulent virus which always produced death of the tissues or whole plant would, as Dr. Smith pointed out, have difficulty in transmission to fresh hosts and thereby in ensuring survival. Such plant viruses, however, while apparently possessing intrinsic virulence for one plant, usually infect other plant hosts without producing symptoms. Variations in virulence can be produced by various procedures which probably favour selectively the multiplication of a virulent variant already present in the virus strain. The emergence of virus mutants under laboratory conditions was also mentioned by Dr. Andrewes, who suggested that the selective survival of mutants showing antigenic variations from the original virus may explain the course of certain human epidemic diseases. From several viruses stable variants can be produced by adaptation to a new host species. The highly virulent virus is able to multiply extensively in invaded host cells, and to destroy these cells with liberation of virus for the attack on further cells. Although the mechanism responsible for cell destruction is not known, recent work with rickettsiæ and influenza virus suggests that these agents in the living state, if present in sufficient concentration, can exert a toxin-like action. Virulence of the animal viruses may also depend upon special tissue affinities, as in the neurotropic viruses. The adaptation of virus to host which results in latent infection may, as in other host-parasite associations, be readily upset.

Prof. A. W. Downie, in summing up the discussion, referred to various points made by previous speakers and suggested that the host-parasite relationship studied under experimental conditions might not show the manifestations of virulence which are evident under field conditions as shown by the behaviour of epidemic disease. We are ignorant of the mechanism by which damage to the tissues of the infected host is produced, and in this field there seems much to be done in the study of the biochemical interactions of parasitic micro-organisms or their enzymes and toxins with the metabolic processes of the host cells.

OBITUARIES

Prof. Robert Newstead, F.R.S.

Robert Newstead was justly proud of the fact that the high place which he achieved for himself in the scientific world, and the distinction which he brought to the Liverpool School of Tropical Medicine and to his adopted city of Chester, were won by him in face of almost insuperable obstacles, associated with an interrupted schooling and an absence of university training or contacts, until he was more than forty years of age.

Newstead, whose death occurred on February 16, was born on September 11, 1859, at Swanton Abbott, Norfolk, and received his early education at a village elementary school, from which he not infrequently played truant in order to be out in the fields and the woods, watching bird- and animal-life. At the age of ten he left school and was apprenticed to the village post and telegraph office, which included also a printer's and stationer's works. There, during the period of the Franco-Prussian War, Newstead became familiar with the processes of printing and studied telegraphy, in which he passed one examination. From telegraphy he passed to gardening and a little farming, devoting his spare time to the study of a small text-book of zoology, from which he taught himself the elements of systematic study, and to the collection of specimens of plant-, animal- and bird-life. One such collection, made primarily for his own pleasure, led to the beginning of his long connexion with Chester. In 1883, at the age of twenty-four, he was invited to exhibit a collection of Norfolk insects, birds and fungi at the Town Hall, Chester. His specimens attracted the attention of the late Mr. Alfred Walker, a disciple of Charles Kingsley and an ardent naturalist, who straightway offered him an appointment in his gardens, partly as gardener, partly as naturalist.

While holding this appointment, Newstead was present at the laying of the foundation stone of the Grosvenor Museum, Chester, and in 1886, when the Museum was opened, he realized one of his early ambitions by being appointed its first curator. The curatorship of the Museum was held for nineteen years, during which time Newstead was responsible for arranging and describing the exhibits in the natural history and archæological sections, both of which were enriched by many specimens which he personally prepared and mounted, not only during his tenure of office, but also long after his retirement; and I have seen him busy with this work after he had passed the age of eighty-five.

In 1906 Newstead was appointed lecturer in economic entomology and parasitology at the Liverpool School of Tropical Medicine, six years after its foundation as the first school of tropical medicine in the world, and at a time when it numbered on its staff such eminent men as Sir Ronald Ross and Sir Rubert Boyce. The importance of Newstead's work now began to receive wider recognition; in 1908 he received the degree of master of science *ex officio* in recognition of his scientific achievements, and in 1911 he was elected first holder of the Dutton Memorial chair of entomology in the University of Liverpool. From that time until his retirement from the chair in 1924, Newstead held a leading place in the world of entomological research. He was dispatched on two scientific expeditions organised by the Liverpool School of Tropical Medicine: first, to

Jamaica in 1908, to make investigations into the causes of the prevalence of sarcoptic mange among cattle; and secondly, to Malta in 1910, to study the bionomics of sandflies. In 1911 he worked on the Royal Society's Sleeping Sickness Commission in Nyasaland, where he spent five months in the bush investigating the breeding-places and habits of the tsetse fly; and during 1913–14 he was a member of the inter-departmental committee on the same disease. During the First World War he was engaged by the War Office to take charge of the Entomological Commission appointed to investigate methods for the control of fly-borne diseases occurring in the camps of France and Flanders, and directed the Liverpool centre of investigation set up by the Royal Society Grain (Pests) War Commission, 1916–20, to deal with the damage caused to grain by insects and mites during transit and in store. He was elected a fellow of the Royal Society in 1912.

Entomology, however, was not the only subject upon which Prof. Newstead was an authority. His appointment as curator to the Chester Museum marked the beginning of his interest in the study of the Roman occupation of Chester. So early as 1899 he was writing on Roman remains which had recently come to light in Chester and Penmaenmawr. In 1914 he began active digging, and from that time onwards, until a few months before his death, he took a large part in excavating, preserving and describing Chester's Roman antiquities. These discoveries and the resultant additions to our knowledge of the Roman occupation were fittingly recognized by the citizens of Chester in 1936, when they conferred upon him the honorary freedom of the city.

During his life-time, Newstead published more than two hundred papers and, since he was an artist of considerable ability, many of them were illustrated by his own hand. As might be expected from such a long, diligent and far-seeking career, these papers covered a wide range of entomological and archæological subjects; but essentially Newstead was a biologist of the old school, a trained observer of Nature, and one who was at his best and happiest in the open air.

We regret to announce the following deaths:

Sir Joseph Barcroft, C.B.E., F.R.S., emeritus professor of physiology in the University of Cambridge, on March 21, aged seventy-four.

Prof. Pierre Janet, well known for his work on psycho-pathology, on February 24, aged eighty-seven.

NEW FELLOWS OF THE ROYAL SOCIETY

At the meeting of the Royal Society on March 20, the following were elected fellows:

Dr. W. J. Arkell, formerly senior research fellow of New College, Oxford, distinguished for his researches on the stratigraphy and palæontology of the Jurassic system; he is the author of valuable palæontological monographs on the Lamellibranchs and Ammonites of the British Corallian.

Dr. G. M. Bennett, Government Chemist, distinguished for his work in organic chemistry on the reactivity and configuration of organic molecules.

W. S. Bisat, civil engineer, Collingham, near Leeds, distinguished for his studies in Carboniferous stratigraphy and palæontology; his methods have been successfully applied in Europe and North America.

Mary Lucy Cartwright, fellow of Girton College and lecturer in mathematics in the University of Cambridge; distinguished for her researches in the theory of functions of a complex variable.

Prof. E. J. Conway, professor of biochemistry, University College, Dublin, distinguished for his work on chemical and physico-chemical processes in living tissues.

Prof. T. G. Cowling, professor of mathematics in the University College of North Wales, Bangor, distinguished for his mathematical contributions to astronomy, the theory of gases, the physics of the ionosphere, and geomagnetism.

J. Craigie, member of the scientific staff of the Imperial Cancer Research Fund, London, distinguished for his work in bacteriology and immunology, and especially for his studies of viruses.

M. B. Crane, head of the Pomology Department of the John Innes Horticultural Institution, London, a notable breeder of new varieties of horticultural plants, whose researches have elucidated the genetical constitution and origin of cultivated English fruit trees and unravelled many problems relating to pollination and the setting of fruit.

Prof. W. J. Duncan, professor of aerodynamics at the College of Aeronautics, Cranfield, distinguished for his contributions to an understanding of flutter in aircraft, and of related problems of elasticity and vibrations.

Prof. M. G. Evans, professor of physical chemistry and head of the Department of Chemistry, University of Leeds, distinguished for his contribution to chemical kinetics and especially for his theoretical work on the modern concepts of reaction velocities.

Dr. W. S. Feldberg, lecturer in physiology, University of Cambridge, distinguished for researches on the mechanism of the humoral transmission of excitation, particularly in relation to the phenomena in which acetylcholine is concerned.

T. Goodey, principal research officer, Institute of Agricultural Parasitology, St. Albans, distinguished for his work on the structure, life-histories and economic importance of nematode worms, particularly those parasitic on plants.

Dorothy Crowfoot Hodgkin, fellow and tutor of Somerville College, Oxford, and University demonstrator in chemical crystallography, distinguished for a long series of investigations by X-ray crystal analysis into the structure of the sterols, proteins and other complex organic molecules.

J. Hutchinson, keeper of the museums, Royal Botanic Gardens, Kew, distinguished for his researches on the taxonomy and affinities of flowering plants and his contributions to the study of the flora of Africa.

Dr. D. A. Jackson, lecturer in spectroscopy, University of Oxford, distinguished for his method for separating close spectral lines and measuring their wave-lengths; by this means he was the first to determine magnetic and mechanical moments of various atomic nuclei.

Prof. G. Jefferson, professor of neurosurgery in the University of Manchester, distinguished for the leading part he has played in the development of the surgery of the brain and spinal cord, in the treatment of head injuries, and for his studies of the physiological disorders resulting from brain injury.

Prof. H. A. Krebs, professor of biochemistry, University of Sheffield, distinguished for his work on intermediary reactions in cell metabolism.

Dr. F. G. Mann, reader in organic chemistry and fellow of Trinity College, Cambridge, distinguished for his work on stereochemistry with particular reference to complex metallic salts and derivatives of arsenic, phosphorus and antimony.

Prof. P. B. Moon, professor of physics, University of Birmingham, distinguished for his researches in atomic physics and for his contributions to the development of micro-wave radar and to the subject of atomic energy.

Dr. E. Orowan, Cavendish Laboratory, Cambridge, distinguished for his fundamental contributions to the physics of metals; his work on plastic deformation, fracture and fatigue is characterized by particular originality and elegance.

Prof. F. A. Paneth, professor of chemistry, University of Durham, distinguished for his pioneering researches in radio-chemistry and for the discovery of free organic radicles of short life; he has undertaken chemical and radio-chemical work in connexion with atomic energy.

Muriel Robertson, head of the Department of Protozoology of the Lister Institute, London, distinguished for researches on the life-cycles of Protozoa and on immunology.

Prof. F. J. M. Stratton, professor of astrophysics, University of Cambridge, fellow of Gonville and Caius College, and general secretary, International Council of Scientific Unions, distinguished for his researches on novæ, and for his part in planning and organising work for the observation of eclipses.

Prof. C. H. Waddington, professor of animal genetics, University of Edinburgh; chief geneticist of the Animal Breeding Research Organisation (Agricultural Research Council); distinguished for his work on experimental embryology and its relation to genetics.

Air Commodore F. Whittle, adviser (engines) to the Controller of Supplies (Aircraft), Ministry of Supply, distinguished for his work on jet propulsion.

NEWS and VIEWS

Coal Gas and Fuel Industries at the University of Leeds: Prof. A. L. Roberts

In 1910 the gas industry endowed the Livesey chair at the University of Leeds to perpetuate the memory of Sir George Livesey, the eminent engineer of the South Metropolitan Gas Company. It was first held by W. A. Bone, who was followed by J. W. Cobb in 1912, and by D. T. A. Townend in 1938. When in 1945 the University granted Prof. Townend leave of absence to take charge of the British Coal Utilisation Research Association (*Nature*, **155**, 783; 1945), Dr. A. L. Roberts, senior lecturer in refractory materials, was appointed acting head, and he has now been appointed to the chair.

Educated at Christ's Hospital, Horsham, Prof. Roberts held an Ackroyd Scholarship at Leeds, and afterwards undertook research under the direction of Prof. R. Whytlaw-Gray into the redetermination of the atomic weight of silicon. In 1930 he was appointed demonstrator in refractory materials in the Department of Coal Gas and Fuel Industries, in succession to Dr. (now Sir) Hubert Houldsworth, a field in which, after collaborative research with Prof. Cobb, he rapidly became eminent. In recent years Prof. Roberts has taken a leading part in the research associated with the gas industry, under the Joint Research Committee of the University of Leeds and the Gas Research Board, for which the University is renowned, specializing in the newer applications of radiant heat to drying, etc., processes. He has also collaborated with the Yorkshire Industrial Gas Development Centre in the development of the permeable lining principle in furnace practice, and with the British Refractories Research Association in an investigation into long-dated effects which occur in siliceous refractories used in carbonizing plant. In another field he has studied the influence of constituent minerals on the working properties of refractory materials, revealing a new species of kaolinitic mineral in plastic fireclays; and during the Second World War he undertook Government work upon the fundamentals of recrystallization of highly refractory materials, an important research since then supported by the Department of Scientific and Industrial Research, and having wide applications, including that in gas turbines, etc. In this connexion he visited Germany in 1945, and has served on a number of Government committees. He has been closely associated with the recent developments in chemical engineering in the University of Leeds, and is a leading figure in local sections of several professional bodies in the Yorkshire area.

Meteorological Stations in the Arctic

The Canadian Government, in close association with the Government of the United States, is planning the establishment of nine meteorological stations in the Arctic. The project will probably take several years to complete, because of the limited period each year during which the sea north of the Arctic Circle is navigable. It is intended that the stations, once established, will be supplied by air. Meteorologists have long felt the need for an increase in the number of stations making regular weather reports in the Arctic regions of the North American continent. The principal requirement is not just for short-lived series of surface observations such as are obtained from expeditions, but rather for the operation of fixed stations making *radio-sonde* measurements of pressure, temperature, humidity and wind over a period of years. The Canadian scheme is therefore expected to provide data of vital importance to general studies on atmospheric circulation and in particular to weather forecasting. This development is of special interest to aviation owing to the increased attention that is being given to the possibilities of inter-continental flying by great circle routes passing over the Polar regions. It is understood that the U.S.S.R. are also anxious to increase the number of meteorological stations in their territory within the Arctic Circle. For this purpose, attempts are being made to develop an automatic weather reporting station that would measure and transmit the values of meteorological elements at regular intervals over a long period.

Ice Accretion on Aircraft

An interesting series of experiments on the Vickers "Viking" airliner by the British European Airways Corporation in conjunction with Messrs. Vickers-Armstrong, the designers and makers of the Viking, has been brought to a successful conclusion. It has been established that the building up of ice on parts of an aircraft can be sufficient to force it down, and that the meteorological conditions necessary to cause this may possibly be met on normal everyday flights. Consequently, equipment for dealing with the trouble must be provided on all machines that are expected to carry out flights to arranged schedules and timetables. Methods already tried out for dispersing this ice are: (i) application of heat, (ii) cracking the ice by causing the surfaces to pulsate, (iii) spraying the parts with a de-icing fluid. The latter system was adopted by Messrs. Vickers-Armstrong, and the experimental machine carrying it was flown by the B.E.A.C., as operators of an air transport line, under conditions chosen to be as bad as possible. The system was tried both by allowing ice to accumulate and then dispersing it, and by keeping the apparatus working and preventing the formation of ice. The fluid is sprayed over the wings, tail and control surfaces by means of porous metal distributors inset at the leading edges. It is pumped to these and carried back over the surfaces by the airstream, and is controlled manually by the crew or automatically by an ice detector. Normal flow is on an intermittent pulsation of one 'on' and four 'off' strokes; but in an emergency this can be increased to a continuous flow. To wet the surfaces quickly, when the system is first switched on, the normal intermittent flow is automatically preceded by a short flooding period of continuous pumping.

Pilot Papers

Pilot Papers, No. 4, is unfortunately not quite up to the standard of previous numbers in point of scientific interest (1, Nov. 1946. Pilot Press, Ltd. 3*s.* 6*d.*). The articles are too scattered in subject-matter and some of them superficial—too long and too 'thin—in treatment. The scattering of interest militates against *Pilot Papers* filling an obvious gap in learned sociological periodicals. Departmental libraries of universities, not to mention university specialists, may well hesitate to subscribe to yet another review for the 'general reader'. One article on the income tax is straight public finance, which is already catered for in economic journals; another is social history in autobiographical form. Two articles, clearly of sociological import, one on the 'squatters', the other on an estate of 'prefabs', are both too long for the common-sense and simple conclusions reached—such as that 'prefabs' are popular; though admittedly data on the 'sense of community' are useful to planners. In particular, the photographs of life among the prefabs might well have been halved without missing the peculiar characteristics of the community. A further article is a popularly written account of progress in psychosomatic medicine. The contribution of perhaps deepest interest deals with the question "Do the Germans Feel Guilty?" by direct interrogation of Germans.

The introductory 'commentary' by the editor, Mr. Charles Madge, is, however, disarming and certainly makes the best of interpreting the material presented. The comment on several articles is that they add something which journalists have missed. Certainly, they are super-journalism, but in the absence of comparison, generalization and interpretation, this does not qualify the essays as social science, such as Mr. Madge's own commentary certainly is. *Pilot Papers* have undoubtedly an important part to play in the advancement of the social sciences, at present so backward in Britain. Let us hope future numbers will concentrate more on an anthropological treatment of modern social relations or on comment thereon, less on *rapportage*, however superior.

Glossaries of Geographical Terms in Different Languages

The Royal Geographical Society, through its Committee on Geographical Names for British Official Use, published during the War a number of glossaries of geographical and other terms used on maps of various countries, most of which do not use the Roman alphabet (London: Royal Geographical Society). These glossaries covered Modern Greek, Russian, Albanian, Serbo-Croat and Slovene, Romanian, Siamese and Turkish. The volumes differ a little in scope, but all are glossaries as apart from gazetteers, and they are not concerned with the transliteration of proper names beyond including alphabets and equivalents. Several incorporate new systems of transliteration. Mr. M. Aurousseau, the secretary of the Place Names Committee, contributes to each volume a general article on the writing of geographical names, with a short bibliography on the subject. There are also articles on various linguistic aspects in many of the volumes. The Turkish volume gives both Arabic and Roman script, and the Siamese volume gives both Thai and Roman. These glossaries are invaluable in the utilization of the maps of the countries concerned; nothing else on so comprehensive a scale has been published for a very long time.

Commercial Flower Production

The Ministry of Agriculture and Fisheries has recently reprinted three booklets on the production of ornamental plants for market. Bulletin No. 109 (London: H.M. Stationery Office. 1*s.* 6*d.* net) deals with summer flowers; Bulletin No. 110 (1*s.* net) describes the horticulture of plants with decorative foliage; and Bulletin No. 112 (2*s.* net) considers the treatment of pot plants. All three bulletins have been written by Dr. H. V. Taylor and Dr. Katharine H. Johnstone. A general section on the raising of seedlings appears in each number, and descriptions of the varieties, cultivation and any special technique are given for each species. Length of text for a particular species is in proportion to its market value, and though the bulletins have no pretence to the encyclopædic, the grower will find that commercial factors have all been dealt with adequately. A number of drawings by L. N. Staniland illustrate the bulletin on foliage; the others have a smaller number of half-tone photographs. Part 1 of the series dealt with spring flowers and flowers grown under glass; it appeared first in 1936. The three booklets now reprinted should provide a modern compendium for growers who may be attempting to restore pre-war floral glories.

Wellcome Marston Archæological Research Expedition

PUBLICATION of the excavations conducted by the late Mr. J. L. Starkey at Lachish (Tell ed-Duwir), Palestine, during 1932–38 is now being resumed. In order to compile a full bibliography, the editor would be glad to know of all articles and other published references to the archæological and linguistic material from the site, particularly those in foreign publications. Copies or extracts, with full references and short summaries of the contents, should be addressed to the Wellcome Marston Archæological Research Expedition, at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1.

Hydrogen-Cooled Turbo-Alternators

THE advantages of hydrogen cooling for large high-speed electrical machines have not up to now been exploited in Great Britain. Several manufacturers are at present engaged on the construction of turbo-alternator units employing hydrogen as a cooling agent. In a report on work and progress in 1946 issued by the Metropolitan-Vickers Electrical Co., Ltd., it is stated that a 60,000 kW., 3,000 r.p.m. set is approaching completion and will be ready for testing shortly.

Prizes for Scientific Instrument Development

THE British Scientific Instrument Manufacturers' Association has received from Mr. W. Bowen a substantial capital sum, the income from which is to be used for the encouragement and development of invention, design, research processes and manufacturing technique in the scientific instrument industry. The Council of the Association has therefore drawn up a trust deed under which the income will be devoted to prizes for employees of members of the Association. This year, five prizes totalling approximately £125 will be awarded for papers coming within the scope of Mr. Bowen's gift. Papers must reach the Secretaries of the Association, Messrs. Binder, Hamlyn and Co., River Plate House, 12/13 South Place, London, E.C.2, from whom application forms can be obtained, not later than April 30.

Colonial Service: Appointments

THE following appointments have been made in the Colonial Service: I. G. Bulmer, to be assistant conservator of forests, Sierra Leone; Captain A. T. Crow, to be geologist, Gold Coast; Captain M. Maughan, to be computer, Lands, Mines and Surveys Department, Uganda; C. A. Gibson-Hill, to be assistant curator, Raffles Museum, Singapore; J. N. Milsum, senior agricultural officer, Malaya, to be chief field officer, Malaya; R. G. H. Wilshaw, senior chemist, Malaya, to be chief research officer, Malaya; H. C. King, assistant conservator of forests, Mauritius, to be senior assistant conservator of forests, Sierra Leone.

The Night Sky in April

FULL moon occurs on April 5d. 15h. 28m., U.T., and new moon on April 21d. 04h. 19m. The following conjunctions with the moon take place: April 8d. 22h., Jupiter 0·6° N.; April 18d. 06h., Venus 4° N.; April 19d. 06h., Mercury 2° N.; April 19d. 07h., Mars 4° N.; April 27d. 13h., Saturn 4° S. In addition to these conjunctions with the moon, Mercury is in conjunction with Mars on April 19d. 23h., Mercury being 1·8° S. Mercury rises about half an hour before sunrise at the beginning of April and attains its greatest westerly elongation on April 5. At the middle and end of the month the planet rises about 20 minutes and 10 minutes respectively before sunrise, and is not favourably placed for observation. Venus can be seen as a morning star, stellar magnitude −3·5, rising at 4h. 40m., 4h. 18m., and 3h. 56m. at the beginning, middle and end of the month, respectively. The visible portion of the illuminated disk varies between 0·748 and 0·820 during April. Mars is too close to the sun for favourable observation. Jupiter can be seen late in the evening in the constellation of Libra, and rises at 22h. 45m. on April 1 and 20h. 35m. on April 30. Its stellar magnitude is −2, and its altitude is not more than 21° in the latitude of Greenwich as its declination is far south. Saturn can be seen up to the early morning hours in the constellation of Cancer, setting at 3h. 31m., 2h. 37m., and 1h. 40m., at the beginning, middle and end of the month, respectively. The following occultations of stars brighter than magnitude 6 take place: April 23d. 20h. 28·4m., 247 B. Taur. (*D*); April 26d. 23h. 15·7m., κ Gemi. (*D*); April 29d. 19h. 56·3m., 46 Leon. (*D*); *D* refers to disappearance, and the latitude of Greenwich is assumed. During April 18–24 the Lyrid meteor shower is active, the radiant being about R.A. 18h., Dec. + 33°.

Announcements

THE following appointments have been made in the University of Leeds: Dr. Philip George, as Brotherton research lecturer in physical chemistry; Dr. G. E. Pringle, as lecturer in inorganic and physical chemistry.

A COURSE of eight lectures on microscopy will be given in the Physics Department, Imperial College of Science and Technology, London, S.W.7, by B. K. Johnson on Tuesdays and Thursdays at 4 p.m., commencing on April 29. The lectures will be accompanied by practical demonstrations and will include modern methods. They will be suitable for those having to use the microscope in technical practice. Application for admission should be made to the Registrar of the Imperial College, Prince Consort Road, S.W.7.

THE twenty-first National Colloid Symposium will be held at Stanford University, Palo Alto, California, during June 18–20, 1947, under the auspices of the Division of Colloid Chemistry of the American Chemical Society. The programme will consist of two groups of papers; one of these will be built about the subject "Colloidal Electrolytes"; the other will be made up of papers on general colloid chemistry. Particulars of the meeting can be obtained from Prof. J. W. Williams, Department of Chemistry, University of Wisconsin, Madison 6, U.S.A.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Use of Punched Card Tabulating Machines for Crystallographic Fourier Syntheses

THE use of 2-dimensional Fourier syntheses in the determination of crystal structures from X-ray data has been well established for some years; but it is becoming increasingly recognized that for detailed determinations these alone are not enough, and that 3-dimensional syntheses are also necessary. The methods of summation which have been used for 2-dimensional work[1], and which employ no other mechanical aids than adding machines, can be applied to 3-dimensional problems, but are then comparatively slow and impose a considerable strain on the computer. Moreover, with rising standards of accuracy, some improvement is desirable on the existing Beevers–Lipson strips which have so far been most commonly used for 3-dimensional work; the 'rounding-off' errors arising from the use of the strips, with their 2-figure accuracy and 6° intervals of computation, may in unfavourable cases lead to displacements of atomic centres by 0·01 A., which is now no longer small compared with the accuracy theoretically attainable[2].

The possibility of carrying out syntheses by means of punched card tabulating machines has been appreciated for some time[3], and several 3-dimensional syntheses have been performed in Great Britain by the Scientific Computing Service, Ltd., while recently Shaffer, Schomaker and Pauling[4] have described a method for use with American tabulating machines. In order to fulfil our requirements for a simplified punched card method, capable of operation locally, we have developed independently the method outlined below; this, while not essentially different in principle from that of Shaffer *et al.*, is considerably simpler, so that the selection of cards can be done by any research worker in a reasonable time and without special training, and can be carried out on Hollerith machines of the type commonly available in Britain. The machines do not have to be adapted specially or set aside for crystallographic work only, so that syntheses or parts of them, occupying, say, two or three hours, can be done in intervals between the normal commercial work of the machines.

We have in effect reproduced Beevers–Lipson strips on Hollerith cards, but with higher accuracy, and, owing to the method of calculation adopted, with a decrease in the number of cards. The 'master pack' of Hollerith cards, for sines and cosines up to order 20, totals 492 cards, while the following advantages over the existing Beevers–Lipson strips are obtained: (*a*) the interval in the argument is 3° instead of 6°; (*b*) the values of the functions are entered to four figures to ensure certain 3-figure accuracy in the final result; (*c*) although cards are punched for amplitudes of 1, 10 and 100 only, the method of working enables any 3-figure amplitudes to be employed.

In practice, we find it convenient to duplicate each card about thirty times, but the number of *different* cards remains 492, and since sines and cosines are never handled simultaneously, the maximum number of different kinds of cards to be dealt with at any one time is 252. With this small number it becomes possible to devise simple systems of picking out the cards required by hand in the laboratory, without the assistance of trained operators or Hollerith sorting machines.

The cards are kept in a pigeon-hole system (details of which are a matter of individual choice) and the 492 pigeon-holes are divided into eight sets according as the cards are sines or cosines; positive or negative; and odd or even multiples of 3° (a particular card contains entries of the function for 3°, 9°, 15°, etc., or 6°, 12°, 18°, etc.; in this way, when circumstances do not justify 3° intervals in the calculations, only the even cards need be used). Each pigeon-hole contains about thirty identical cards.

The selection of the cards for a synthesis follows the same general lines as for the selection of Beevers–Lipson strips, with one important difference. Nine 'digiting cards' are laid out in order and numbered 1 to 9; a 3-figure amplitude (say, 359) is selected by picking one each of the appropriate 1, 10 and 100 cards, and placing them on the 9, 5 and 3 digiting cards respectively. This process is repeated until all the amplitudes required have been selected, and the nine packs of cards are then put together in order, and are ready to be checked and go through the tabulating machine (usually with other similar packs for other parts of the calculation, separated by spacing cards).

Avoidance of errors in hand-picking is largely a matter of the lay-out of the pigeon-hole system and the establishment of a suitable routine; but as complete freedom from error cannot be assumed, the odd and even cards, which are picked separately and should be identical as regards amplitude and order, are put through a comparing reproducer, which detects differences between the two sets.

In the tabulator, each entry on the cards is multiplied by the number of the adjacent digiting card before being incorporated in the appropriate total; it is for this reason that entries on the cards are made to four figures, so that the effect of rounding off the fifth place, even when multiplied by nine, cannot affect the accuracy of the third place.

The results of the tabulation (either actual electron densities or intermediate data according to the stage of the syntheses) may be printed on paper or punched on Hollerith cards (for filing or subsequent use), or both. To complete the work, the cards which have been used are sorted back into pigeon-hole order on a sorting machine.

The time taken for a synthesis depends upon the particular circumstances of each case, but the order of magnitude may be inferred from the following example. We evaluated the appropriate 3-dimensional section to locate one of the central (CH_2) carbon atoms in dibenzyl, using 3-figure values of the structure factors determined by Jeffrey[5]. The whole operation took two persons approximately ten hours, of which about half was spent in the laboratory selecting and preparing the cards, and half at the machines, comparing, tabulating and re-sorting. There was an appreciable loss of time on account of the improvised nature of our pigeon-hole system and of our inexperience, so that we think with practice it should be possible to reduce the time for a similar computation by several hours.

Nevertheless, it will be clear that to determine, by our method, the electron density throughout, say, one quarter of a unit cell, involving perhaps sixty 3-dimensional sections, would be a very lengthy process. We wish, therefore, to emphasize that it has not been our aim to provide for comprehensive syntheses of this type, which are not necessary in dealing with the comparatively small molecules in which we are interested, and which at the present time can be carried out efficiently only by a centralized computing service, to which our method should be regarded as complementary. Our procedure, which we consider to be sufficiently simple to be within the reach of any laboratory engaged on accurate structure analysis, is particularly adapted to the evaluation of electron densities with good accuracy over limited areas; for example, in regions where atoms are indicated by 'trial and error' or other preliminary investigations. The methods of selecting the cards and of tabulating confer a flexibility which enables this to be done with equal ease for any part of the unit cell, and by restricting calculations to regions which contain details of interest, it becomes feasible to use the Hollerith method not only for final syntheses but also for some, at least, of the preceding ones too.

We shall be glad to give working details of this method to anyone who is interested.

We wish to thank Mr. W. McL. Wishart and Mr. J. L. Ineson of the Central Electricity Board for placing Hollerith machines at our disposal, Messrs. Bartindale, Cruickshank, Gillot, Nyburg and Stadler for help in carrying out trials, and Mr. J. Grant of the British Tabulating Machine Co. for his helpful interest.

Orientation of Fibrils in Natural Membranes

In recent years, several studies of the orientation of chitin and protein chains in the insect cuticle[1,2] and of cellulose chains in plant cell walls[3] have appeared. Between 1938 and 1940, X-ray, optical and chemical studies of the cuticle of annelids and nematodes were made by one of us (L. E. R. P.) with the idea of obtaining information about the structure of other types of natural membranes. The cuticles of these animals are largely composed of fibrils of a protein belonging to the collagen group, distributed with their long axes in the plane of the cuticle and in two preferred orientations with respect to the long axis of the body. In annelids, such as *Aphrodite* and *Lumbricus*, the fibrils cross at *c.* 90°, and each set makes an angle of *c.* 45° with the long axis. In *Ascaris*, the two sets make an angle of *c.* 135° with each other and of *c.* 70° with the long axis. An arrangement of this kind may be mechanically advantageous, since the resulting membrane is capable of anisometric extension, though the individual fibrils are inextensible.

It has been suggested[4] that the cellulose chains in plant cell walls are deposited in sheets, alternately oriented in one or other of two preferred directions, and that this orientation depends on control exercised by the protoplasmic surface of the cell. The preferred orientation of fibrils in membranes bounding grossly macroscopic organisms, such as round and bristle worms, where the cuticle is formed by a hypodermis composed of millions of cells, would seem to require a high degree of co-ordination of the activities of these cells, if orientation depends on the protoplasmic surface beneath the cuticle. The mechanical aptness of fibrillar orientation in the cuticle, however, invites an alternative hypothesis: that shear and/or tension forces acting during secretion may be responsible for the observed orientation.

In the filamentous alga *Chætomorpha linum*, it has been shown[5] that both longitudinally and transversely oriented cellulose chains are present in each of the microscopically visible lamellæ of the cell wall. A macroscopic system in some respects similar has been studied in the cocoon of the chrysomelid beetle *Donacia*. Although first deposited as a viscid mass surrounding the larva[6], this barrel-shaped, chitinous cocoon afterwards hardens, becomes laminated, and exhibits positive birefringence with respect to the shorter diameter after freeing from sclerotin. The organisation of the cocoon cannot in this case be due to the intervention of a protoplasmic surface. Recently, one of us (M. M. S.) has shown that the thinnest single laminæ which can be separated from the *Donacia* cocoon are mosaics of birefringent and isotropic regions. If the extinction directions in a number of laminæ are plotted against frequency in a polar diagram, it is found that the chitin chains are oriented predominantly at 45° and 90° to the long axis of the cocoon.

These observations on different types of macroscopic cuticular membranes suggest that (*a*) 'crossed fibrillar'[3] orientation can occur at the surface of cylindrical units of a very different order of size from that of single cells; (*b*) preferred orientation of fibrils with respect to the morphological axes of the unit may be due to mechanical forces acting during deposition; (*c*) contact with a protoplasmic surface is not essential for the formation of a laminated membrane with two preferred orientations of chitin chains; (*d*) preferred orientation in two directions may occur within a single microscopic lamina of a multilaminate, macroscopic membrane.

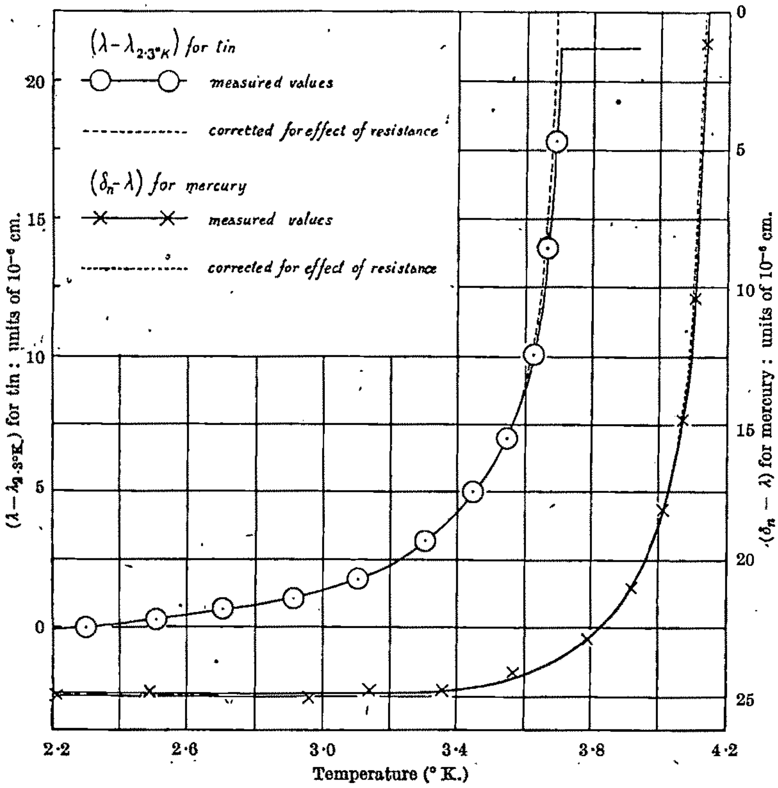
A New Method for Determining the Penetration Depth in Superconductors

It is a well-known property of high-frequency electrical transmission lines[1] operating in the normal mode that the velocity of propagation of a wave along the line is given by the equation $v = 1/\sqrt{LC}$, where L and C are the inductance and capacitance per unit length. But whereas for all frequencies used in practice the value of C is simply the electrostatic



capacity between the conductors, the inductance must be considered as the sum of the two quantities, usually referred to as the internal and external inductances. The latter, $L_{\text{ext.}}$, is the value that would be assumed by the inductance if all the current were to flow on the surface, and the internal inductance, $L_{\text{int.}}$, represents a correction, very small at high frequencies, due to the finite penetration of the current into the body of the conductors. If the internal inductance be neglected, as indeed is common, the velocity is found to be in general the velocity of propagation of a plane unbounded wave in the dielectric medium surrounding the transmission line. The effect of the internal inductance is to alter the velocity by a factor $(1 - L_{\text{int.}}/2L_{\text{ext.}})$.

For the special case of the parallel-wire transmission line, formulæ have been developed for the capacitance and external inductance of the line; in order to take into account the internal inductance, the simplest procedure is to calculate C from the actual dimensions of the line, but for the calculation of L to imagine the radii of the conductors to be reduced by a quantity δ, which represents the effective skin-depth of the current. It is easy to show that for a normal metal obeying the classical conduction equation $J = \sigma E$, δ takes a value equal to one half of the skin-depth as usually defined, that is, $\delta = \dfrac{1}{2\sqrt{2\pi\omega\sigma}}$, while for a superconductor obeying the equations of F. and H. London[2], δ is the same as the penetration depth, λ.

Now it is very difficult to measure the velocity of propagation sufficiently accurately to determine δ directly, but it is a far easier problem to measure with considerable accuracy small changes in the velocity due to variations of δ. It was observed during experiments on the radio-frequency resistance of superconductors at a wave-length of 25 cm., using the parallel wire resonator described previously[3], that a change in resonant frequency occurred when superconductivity was destroyed by a magnetic field. Clearly there must be an alteration in the velocity of propagation, which is associated with a difference in the values of δ for the superconducting and normal states. This phenomenon may be used in certain circumstances to measure variations of λ with temperature; but unfortunately there seems to be little hope at present of using it for an absolute determination of λ, since a detailed investigation, to be published elsewhere, has verified the suggestion of H. London[4] that most metals at very low temperatures behave anomalously owing to the very long mean free paths of the electrons. Consequently, it is not possible to calculate the value of δ_n in the normal state from a knowledge of the skin resistance. If, however, as in the case of tin, the normal skin resistance, and hence presumably δ_n, is constant within 1 per cent between 4° K. and zero, measurements at various temperatures of the resonant frequency change which occurs when the magnetic field is applied enable the variation of λ with temperature to be studied. This variation is shown in the diagram, from which it may be seen that the method is capable of an accuracy of about 1 per cent.

The present determination was made without any refinement of the apparatus beyond that required by the resistance measurements already quoted, and the estimated probable error is $\pm 0{\cdot}2 \times 10^{-6}$ cm. Just below the transition temperature, it is necessary to apply a small correction for the influence of the radio-frequency resistance on the depth of penetration. The theory of this correction will be discussed in a more detailed account of the experiments to be published elsewhere.

On the same graph is shown the variation of the difference between δ_n and λ for mercury, but since here the normal skin resistance, and hence probably δ_n, varies with temperature, the interpretation of the curve is more difficult. It may be said, however, that this curve does not exhibit any gross divergences from the more direct determinations of λ[5]. Preliminary (unpublished) measurements on tin by the same authors show qualitative agreement with the results of the present method.

In conclusion, I should like to express my thanks to Dr. M. Désirant for his help in carrying out these experiments.

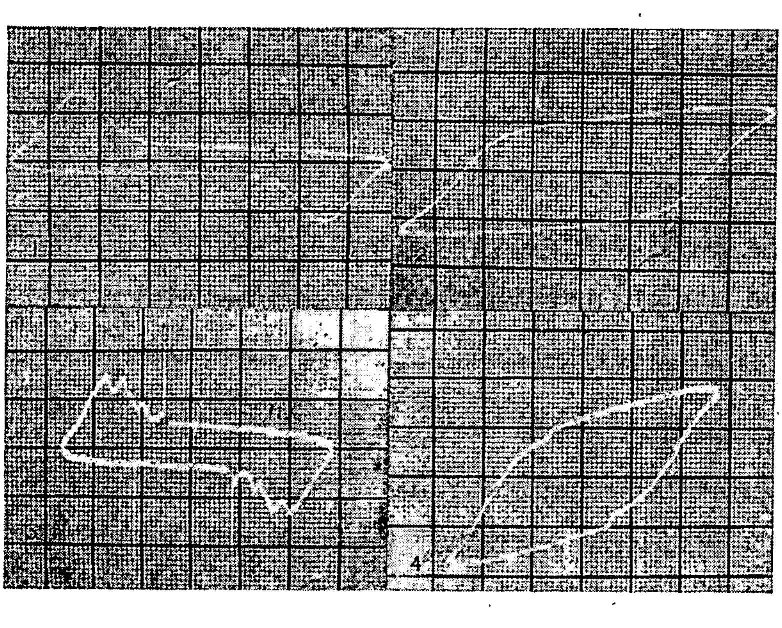
A New Method of Studying the Structure of Alloys by Magnetic Analysis

In testing metal wires for ferromagnetism in this laboratory, a cathode ray oscilloscope is used to exhibit either of two curves, one showing the variation with the external field strength H of the rate of change of magnetic intensity $\frac{dJ}{dt}$ in a single wire, the other the hysteresis loop J v. H. By a simple calculation the values of the former can be transformed into values of $\frac{dJ}{dH}$, that is, the differential susceptibility, K_d.

With wires of homogeneous material, both traces appear as smooth curves throughout the range of applied field strengths (Figs. 1 and 2). The differential curve shows a pronounced peak or bulge corresponding to the steepest part of the hysteresis loop, the general form of the curve being very similar to those given by Bozorth and Dillinger in their classical work on the volume concerned in a Barkhausen discontinuity.

A number of 'tested' wires, however, have shown pronounced irregularities in this curve in the form of subsidiary peaks which in extreme cases rise like needles to a height exceeding that of the main peak of the curve (Fig. 3; the largest peak, although visible on the negative, was insufficiently defined for adequate reproduction, and has, therefore, been drawn in to the same height as on the negative). They may occur singly or in clusters, which usually contain at least one main peak, and several such clusters may be exhibited on one curve. With an applied field in excess of the value at the main peak, these irregularities are spaced over the portion of the curve corresponding to the section of the hysteresis loop between the knee of the demagnetization quadrant and the steepest part; and it has been found that the values of H at which they occur remain constant as the applied field is reduced, although the optical effect is that of movement towards the main peak, since the latter occurs at lower values of H with low applied field strengths. The more pronounced of these irregularities are easily observed as step discontinuities in the hysteresis loop (Fig. 4).



4

Since the irregularities are found to vary in intensity as different points on the same wire are examined, it is obvious that they are caused by inhomogeneities of structure such as may be due, for example, to imperfect annealing. It is considered that they represent 180° reversals of demagnetized domain orientation of magnetization at values of H corresponding to the critical value H_0 for different ferritic combinations of the constituents of the wire, and that their appearance in any material would indicate the presence of alloy micro-structures (whether agglomerates or transition zones) of differing coercivities.

Further investigation is proceeding, and it has already been found that in certain circumstances the effect can be produced by suitable heat treatment of an otherwise normal wire at temperatures which are known from other sources to be suitable for precipitation processes at grain boundaries for the alloy examined.

The method described would, therefore, appear to be suitable for the examination of the structure of inhomogeneous alloys exhibiting ferromagnetism. This preliminary account is put forward as possibly of interest to other investigators, since, so far as is known, no other observations of this type have been published.

Radioactivity of Radioaluminium

In a recent letter in the *Physical Review* by Sachs[1] and one in *Nature* by Allan and Clavier[2], and in several papers during the war years, reference is made to the disintegration of radioaluminium according to the reaction

$$^{28}\mathrm{Al} \rightarrow {}^{28}\mathrm{Si} + e^{-}.$$

The β-particle spectrum has been measured by Cork, Richardson and Kurie[3], who find a maximum energy of 3·3 MeV., and by Eklund and Hole[4], who find a maximum of 2·98 (± 0·18) MeV. The shape of the spectrum suggests a simple transition. γ-Radiation has been observed and estimated as 1·8 MeV. by Itoh[5], and 2·05 (±0·15) MeV. by Eklund and Hole[4].

A paper by Watase[6] in 1941 described coincidence experiments which showed that all β-particles from radioaluminium were followed by the same amount of γ-radiation. There was no evidence for γ-rays in cascade.

Absorption and coincidence experiments were carried out by me in 1939 [7,8], which are in full accord with the Japanese work and showed that the β-spectrum was substantially simple. The maximum energy of the β-particle spectrum was estimated as 3·10 (±0·10) MeV., and no change in β–γ coincidence-rate per β-particle was observed up to absorption thicknesses of 480 mgm. per sq. cm. of aluminium. No γ–γ coincidences could be detected, and the β–γ coincidence-rate per γ quanta indicated that all γ-quanta were correlated with the main β-particle spectrum. It is therefore certain that in most aluminium disintegrations a simple β-particle spectrum of maximum energy about 3 MeV. is followed by a single γ-quantum. The coincidence experiment gave a net efficiency of detection of the γ-quanta corresponding to an energy of 2·15 MeV., in rough agreement with the estimates given above.

Accepting the energies given by Eklund and Hole[4], the disintegration energy of radioaluminium is 5·03 (± 0·23) MeV., and not a value of about 3 MeV. as given by Mattauch and other investigators[1,9,10].

Occurrence of a Monotropic Transformation in Trinitroanisole

A STRIKING example of the persistence of the metastable crystalline modification of a substance in the absence of nuclei of the stable form has recently been experienced in this Laboratory.

During the seven months prior to January 18 of this year, all efforts to prepare pure trinitroanisole here, either from picryl chloride or from dinitroanisole, consistently resulted in producing a substance melting sharply at 57·5° C. as compared with the figure of 68° C. normally expected for trinitroanisole. Ultimate analysis gave the results to be expected for this material, and somewhat elaborate chromatographic treatments served to confirm its high state of purity.

A sample of normal trinitroanisole melting at 68° C. was introduced into this Laboratory on January 18, since when all fresh local preparations of the substance have melted at 68° C. Moreover, all material previously melting at 57·5° C. was almost immediately transformed to the more stable modification on exposure to the air of the laboratory.

β-Trinitroanisole was prepared afterwards by sealing small quantities of the stable α-form in glass tubes, which were then completely immersed in boiling water to destroy all crystalline form. After supercooling, crystallization was induced by means of loose pieces of glass rod originally introduced with the crystals. In this way, the β-form was usually produced, and could be preserved for some time in the metastable state. When such a tube was broken in a 'contaminated' atmosphere, transformation commenced almost immediately, even above the melting point of the β-form.

By inducing crystallization of the β-form at the centre of a supercooled film on a microscope slide, the transformation could be initiated at a corner of the film and observed through a polarizing microscope. The rate of transformation, as measured by the movement of the new crystal face across the film, became slower with rise of temperature, thus confirming the monotropic nature of the change.

There is an interesting historical aspect of this observation. In 1903 Holleman[1] expressed his astonishment at his failure to prepare trinitroanisole melting above 58° C. He sent a sample of his material to Hantzsch[2], who stated that when it was purified he obtained material of normal melting point. There seems no doubt now that Holleman's preparation consisted of the metastable form, and it is conceivable that when Hantzsch exposed it to the air of his own laboratory it would have been transformed without the necessity for further purification. In 1924 Van de Vliet[3], who is believed to have worked in the same laboratory as Holleman, published further evidence in support of a melting point of 58° C., having failed to obtain a higher figure. Evidently this is a case where the metastable form persisted for more than twenty years.

I wish to thank Dr. O. L. Brady, of University College, London, for his interest and suggestive comments in connexion with the transformation.

The Boron-Trifluoride Catalysed Reaction of Di-isobutene

THE polymerization of isobutene and the dimerization of di-isobutene are both catalysed by Friedel–Crafts catalysts. Earlier work on these reactions has led to the conclusion that a third component, other than the Friedel–Crafts catalyst and the monomer, is necessary for an appreciable reaction-rate to occur; and it has been shown, in particular, that the rapid polymerization of isobutene in the gas phase, using boron trifluoride as catalyst, does not occur if these reactants are pure, but does occur if a trace of water is present[1].

We have now used high-vacuum technique to study the reaction of di-isobutene in the gas phase at room temperature with boron trifluoride as catalyst. The pressures of di-isobutene and of boron trifluoride were each of the order of 20 mm. Unpurified di-isobutene vapour reacts rapidly on mixing with boron trifluoride. (The reaction is observed by the fall in pressure.) Di-isobutene vapour, purified by several distillations *in vacuo* over freshly distilled sodium at 60° C., does not react on mixing with boron trifluoride.

Di-isobutene vapour, purified in this way, was mixed with boron trifluoride, and to this non-reacting mixture a small quantity (2–3 mm. pressure) of the vapour of some third component was added. In some cases the addition of the third component caused the di-isobutene to react rapidly. This occurred when the third component was water or acetone. In these experiments the boron trifluoride combined instantaneously with the added vapour of the third component in approximately equal molar quantities. The acetone was purified by distillation *in vacuo* over freshly distilled sodium.

In other cases, the addition of the third component did not produce a rapid reaction of the di-isobutene, and the boron trifluoride did not combine with the added vapour. Examples of this class which we have studied are oxygen, hydrogen sulphide and hydrogen chloride. In each of these cases, the final addition of water vapour to the non-reacting mixture produced rapid reaction.

The addition of ammonia vapour to the non-reacting catalyst-monomer mixture results in the instantaneous combination of the ammonia with the boron trifluoride, in approximately equal molar quantities, but has no effect upon the di-isobutene reaction. The subsequent addition of water vapour to this mixture produces the rapid reaction of di-isobutene.

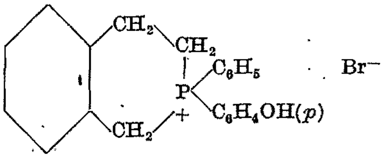
An Optically Active Quaternary Phosphonium Salt

OF organic derivatives of phosphorus (that is, containing C—P links), the only type which has hitherto been resolved into optically active forms is that represented by the general formula $R^1R^2R^3P\rightarrow X$, where R^1, R^2 and R^3 are different alkyl or aryl groups and X is either oxygen or sulphur: Meisenheimer *et al.*[1] have resolved tertiary phosphine oxides, for example, phenyl-benzyl-methyl-phosphine oxide, and Davies and Mann[2] have similarly resolved phenyl-*p*-carboxymethylphenyl-*n*-butyl-phosphine sulphide.



We have now developed a general synthesis of 2 : 2-diaryl-1 : 2 : 3 : 4-tetrahydro-*iso*-phosphinolinium salts. One member of this series, namely, 2-phenyl-2-*p*-hydroxyphenyl-1 : 2 : 3 : 4-tetrahydro-*iso*-phosphinolinium bromide (see formula), we have resolved through the *d*-camphor sulphonate and isolated in the optically pure state having $\alpha_D + 0{\cdot}34°$, $[M]_D + 32{\cdot}9°$. This bromide shows considerable optical stability and undergoes no perceptible racemization when boiled in alcoholic solution.

This, therefore, represents the first example of an optically active quaternary phosphonium salt, a compound which, in general structure, is closely related to 2-phenyl-2-*p*-chlorophenacyl-1 : 2 : 3 : 4-tetrahydro-*iso*-arsinolinium bromide, the resolution of which we have recently recorded[3].

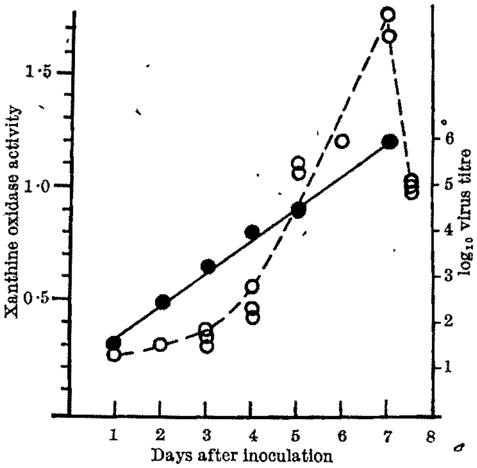
Xanthine Oxidase and Virus Growth

So far as is known, viruses appear to possess no enzyme activity; the virus particles, in order to multiply, must presumably utilize the enzyme-substrate reactions of the host cells, or else have a selective affinity for the products of host metabolism. It is thus possible that an investigation of the biochemical activities of tissues containing a growing virus might disclose an abnormality of enzyme action which would yield information upon the metabolic activities of the virus itself. With this object in view, preliminary studies have been carried out upon the xanthine oxidase content of the brains of mice with yellow fever encephalitis.

A group of mice were inoculated intracerebrally with 10^5 LD_{50} of the 17D strain of yellow fever virus. Each day after the inoculation a mouse was selected at random, the brain was removed, ground with 5 c.c. distilled water and centrifuged. The supernatant fluid was tested for xanthine oxidase activity by the Thunberg technique; a part of the supernatant liquid was also inoculated into mice in serial decimal dilutions in order to determine the titre of virus present. The results are shown in the accompanying graph.



●, virus titre. ○, xanthine oxidase activity

The titre of virus in the brain rises steadily to a maximum of 10^6 on the seventh day, when symptoms of encephalitis appear. Throughout this incubation period the amount of xanthine oxidase in the brain (expressed in arbitrary units) also rises. The normal level of enzyme activity in mouse brain lies between 0 and 0·2 in the units adopted; in the mouse brain infected with yellow fever virus, the activity rises to a value of 1·7 at the time of onset of symptoms. As paralysis increases the enzyme content falls, and reaches a value of 1 or less when the animal is moribund. Similar results were obtained with the neurotropic and Asibi strains of yellow fever virus, and with the virus of lymphocytic choriomeningitis.

The question naturally arises as to whether the observed increase of enzyme content in these virus infections is significant or purely a chance finding. As encephalitis develops, a round-cell infiltration of the brain appears, and it might be that these round-cells, presumably lymphocytes, attracted to the brain by an unknown stimulus, bring xanthine oxidase with them in an incidental manner. This point was investigated in two ways:

(*a*) Brains were removed at daily intervals during the incubation period. Each was divided into halves longitudinally; the xanthine oxidase activity of one half was determined while the other was fixed, sectioned and stained with hæmatoxylin and eosin. It was found that the xanthine oxidase activity had already considerably risen by the second day, whereas cellular infiltration did not appear until the third day and was not prominent until the fourth day after inoculation.

(*b*) Determinations were made of the desoxyribonuclease activity of normal and virus-containing mouse brains. No significant difference was found. This enzyme is present in large amounts in mouse lymphatic tissue; since the cellular infiltration is insufficient in amount to produce a detectable increase of desoxyribonuclease activity, it is not likely that it is responsible for producing the observed rise of xanthine oxidase activity, which at times amounts to ten times the normal value.

The evidence, therefore, does not support the view that xanthine oxidase is introduced into the brain by the accumulation of inflammatory cells, as it begins to increase in amount some considerable time before cellular infiltration appears. This being so, it is possible that the presence of the virus brings about in some way the accumulation of xanthine oxidase, perhaps by a selective affinity for it which is greater than that of the host tissues, and that the enzyme is an essential growth factor which is required for virus multiplication.

The Premaxilla and the Ancestry of Man

IN 1914 I had the privilege, thanks to the kindness of the late Prof. Fawcett, of studying the development of the human facial bones in his unique series of embryonic crania. In 1918, as a result of this investigation, I stated in my first publication on the "Ancestry of Man" that absence of the premaxilla on the human face was "a human specific character", and that from its very precocious ontogenetic development it might be presumed to be a very early phylogenetic acquirement. This statement received a certain amount of adverse criticism, but I repeated it and amplified it again in "Man's Place among the Mammals" in 1929.

At the time I did not realize that my findings were merely a repetition of those made by G. W. Callender in his forgotten paper of 1869. In that paper Callender had shown that in man the premaxilla is "shut off from the face by the nasal and incisor processes of the superior maxilla". Afterwards, Dr. E. H. Johnson, working in my department in the University of Melbourne, repeated the whole of the work on the development of the upper jaw in 1936. These results may be briefly summarized:

(1) Notwithstanding the numerous statements to the contrary, the suture between the maxilla and premaxilla is never present on the human face at any pre- or post-natal stage. This is so because

(2) in early embryonic life the maxilla of each side grows forwards over the *anlage* of the premaxillæ and, by meeting in the middle line of the upper jaw, buries them completely on their facial aspect.

(3) In this way those parts—the portion of the upper jaw bearing the incisor teeth and the narial margins—which in monkeys and apes are formed superficially from the premaxilla are, in man, constituted by the medially growing incisor and nasal processes of the maxilla.

(4) The division between the superficial maxilla and the buried premaxilla in man is marked, as Jarmer showed in 1922, by the interalveolar suture; for in man alone are the sockets for the incisor teeth formed from maxilla labially and premaxilla lingually.

This striking fact of the fundamental difference between man and any other of the existing Primates in the architecture of the upper jaw appears to have been completely overlooked in assigning the rank of 'hominid' or 'man-apes' to the Taungs and Sterkfontein skulls. *Australopithecus* and *Plesianthropus* show definite facial maxillary–premaxillary sutures in typical simian form, and *Paranthropus* fails to show it only because the individual is over the age at which it is obliterated and not at all because the condition is 'as in man'.

Whether the orthograde bipedal posture and the other attributes that have been claimed for these South African forms will ultimately be established is a question that only time and further discoveries can solve. But meanwhile it can be asserted with every possible assurance that all of them are apes, and that they throw no light whatever on the primate forms that were ancestral to *Homo*.

Species of Sulphur Bacteria Associated with the Corrosion of Concrete

IT has already been shown[1] that in the highly acidic end-products of corrosion of concrete sewers exposed to atmospheres containing hydrogen sulphide, there are present large numbers of a sulphuric acid-forming species of sulphur bacterium provisionally named *Thiobacillus concretivorus*. Further, it has been shown[2] that the typical corrosion process is a case of bacterial corrosion; it cannot proceed under sterile conditions and can only be carried to the acid stage through the activity of this organism. It is typical of this form of corrosion that the *p*H of the products falls continuously as the corrosion process becomes established. As the organism cannot exist at a higher *p*H than 6·5, its activity could not explain the initial stage of the process in which the *p*H of the fresh concrete surface (11–12) falls to 6·5 or less. It was then suggested that this preliminary drop in *p*H could be brought about either by purely chemical reactions or by the activity of further species of bacteria.

I have now isolated, from the corrosion products of concrete in the early stages of corrosion, two other groups of bacteria the activity of which explains this preliminary drop in *p*H.

The first group appears to be a homogeneous single species characterized as follows: the organisms are strictly autotrophic Gram-negative bacilli which rapidly oxidize thiosulphate to sulphate, polythionate and elemental sulphur, forming a pellicle of sulphur and reducing the pH of the culture medium to 3·0–3·3. They grow in a hydrogen sulphide atmosphere, in culture media containing excess calcium carbonate, forming a pellicle of sulphur and reducing the pH to the same value as with thiosulphate. They oxidize elemental sulphur slowly with the formation of sulphate, but do not oxidize alkali sulphides. The range of pH over which they exist varies slightly from strain to strain. It is between the approximate limits of 3·5–8·5; but these depend to some extent on the pH of the corrosion products from which the strain is isolated. This group resembles in many respects the species *Thiobacillus thioparus* isolated by Nathansohn[3] and studied by Beijerinck[4] and Starkey[5,6,7].

The second group consists of a miscellaneous collection of species characterized by considerable variation in colony form and morphology, but they are all facultatively autotrophic and grow profusely on nutrient media. They slowly oxidize thiosulphate to polythionates and sulphate without the formation of elemental sulphur, and in fact show little evidence of growth in mineral media; the pH first rises and then slowly falls to the initial pH of the medium. They tolerate a wide range of pH (2·0–10·5), but the optimum for growth is between 7 and 10. They can exist in a hydrogen sulphide atmosphere with calcium carbonate in the culture medium, but will not grow with elemental sulphur or sulphides as the source of sulphur.

By the use of mineral media of appropriate pH and sulphur source, and by making tenfold dilutions of samples of the extract from corrosion products, it is possible to obtain an approximate count of the numbers present of each of the three groups of bacteria associated with the corrosion process. Such counts performed on corrosion products of varying pH are shown in the table.

Sample of corrosion product	pH of sample	Dilution of sample to show growth		
		Th. concretivorus	*Th. thioparus*-like group	Miscellaneous group
A	9·88	Nil	10^3	10^6
B	7·52	Nil	10^6	10^6
C	5·77	Nil	10^6	10^5
D	4·03	10^5	10^1	10^1
E	3·42	10^6	Nil	Nil
F	2·18	10^6	Nil	Nil

Each of the three groups predominates at different stages of the corrosion process, the miscellaneous group of facultative autotrophs in the initial stage (pH 11–9), the *Th. thioparus*-like species between pH 9 and pH 5, while *Th. concretivorus* alone is present during the final stage of free acid formation below pH 5.

Evidence concerning the formation of intermediate products has been obtained by the exposure of sterile material to a hydrogen sulphide atmosphere. It has been found that on sterile fresh concrete small amounts of thiosulphate and polythionate are formed, while elemental sulphur is produced on sterile samples of the acidic end-products of corrosion. The whole corrosion process may, therefore, be explained as follows: the exposed walls of new concrete sewers with an initial pH of 11–12, on exposure to an atmosphere containing hydrogen sulphide, are subject to a twofold chemical change. Normal carbonation lowers the pH to 8·4 (the pH of the carbonate–bicarbonate–carbon dioxide equilibrium), and fixation of hydrogen sulphide as thiosulphuric and polythionic acids further lowers the pH to about 7·5.

While these purely chemical changes are taking place, there first occurs bacterial proliferation of the miscellaneous group of slow thiosulphate oxidizers. The oxidation by this group of the sulphur acids formed chemically does little to assist the drop in pH and may actually retard it. As the pH drops below 9, the *Th. thioparus*-like group then multiply, and their oxidation of thiosulphate and polythionate to sulphur and sulphuric acid results in a rapid drop in pH. This continues until the pH falls below 5, when *Th. concretivorus*, first by oxidation of sulphur formed by the *Th. thioparus*-like group and later by oxidation of the sulphur formed chemically, produces high concentrations (1–5 per cent) of free sulphuric acid, and so brings about the final products of corrosion typical of the process.

The early stage prior to the development of the *Th. thioparus*-like group is the slowest, and the corrosion increases in rate with the proliferation, first of the *Th. thioparus*-like group and then the *Th. concretivorus* group.

While the primary corrosive agent is hydrogen sulphide, none of the groups of bacteria concerned can utilize sulphides directly for growth. It is through the intermediate production of thiosulphates, polythionates and sulphur, by chemical means, that the corrosion process proceeds.

The detailed description of these bacteria and their function will be dealt with elsewhere.

I wish to thank Mr. E. F. Borie, the chief engineer of sewerage, Melbourne and Metropolitan Board of Works, for permission to publish this communication.

A Sensitive 'Cartesian Diver' Balance

IN experimental cell physiology, the main difficulty often is how to obtain a reliable measure of the amount of protoplasm showing the biological (enzymatic, respiratory) activity studied. Dry weight[1] or nitrogen-content[2] of the whole object may be measured, but the measurement involves the death of the object. We use the 'reduced weight' of an object, namely, the buoyancy (usually negative) when suspended in water. The reduced weight of small objects was measured by Linderstrøm-Lang[3], but the cells were injured by the procedure. The present method permits the measurement of the reduced weight of small living objects, which are not damaged by the procedure and may thus be studied again and again.

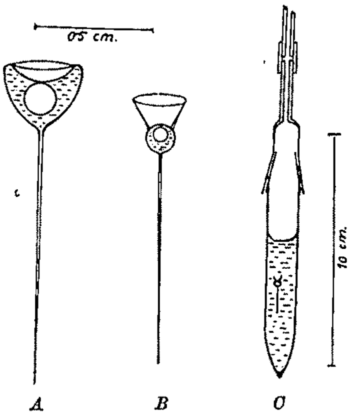
The principle of the balance is that of the Cartesian diver[4]. An air bubble (about 0·1 µl.) makes the balance float in water. The air bubble with some water is enclosed in a chamber which opens to the surroundings through a long narrow capillary, so that pressure variations in the flotation vessel are transmitted to the air bubble, while loss of air by diffusion is restricted.

The change in equilibrium pressure (p_x) due to charging the balance with an unknown weight (reduced weight = $R.W_x$) is compared with the change (p_{st}) resulting from the charging with some known weight (reduced weight = $R.W_{st}$). $R.W_x$ is calculated from the equation

$$R.W_x = R.W_{st}\,\frac{1-\dfrac{B}{B-p_x}}{1-\dfrac{B}{B-p_{st}}},$$

B being the normal barometric pressure. B, p_x and p_{st} are expressed in centimetres of water.

Larger balances of glass (Fig. A, air volume 0·5–1·0 µl.) could be blown when heating was carried out with a glowing platinum wire. However, the smaller balances (0·04–0·15 µl.) extensively used (B) always turned out too heavy when made entirely of glass; so the scale is made of polystyrene (sp. gr. 1·05). Polystyrene is dissolved in benzene, and the solution is blown so as to form a bladder, which is made to adhere to the glass of the diver balance. After evaporation of the benzene, the bladder hardens, so that it can be separated into two halves using a razor. The lower half adheres as a scale to the diver balance.



As standards for the weighings we use small gold weights the reduced weights of which are determined in the gradient tube[5]. In routine work with the balance, however, it has been found more convenient to use small polystyrene weights, which are more easy to handle with a pipette. The whole equipment for measurements with the balance is the same as that used in the work with the Cartesian diver microrespirometer[6]. The flotation vessel with the balance is shown at C.

The present method has been worked out for the accurate study of large amœbæ (*Chaos chaos* L.), the volume of which in most cases ranges from 0·01 to 0·1 µl., corresponding to reduced weights of about 0·2–2 γ. Since the error of the method in routine work is ± 0·02–0·03 γ, and with very small balances only ± 0·01 γ, this means that even very tiny objects can be studied with a fairly good accuracy. A complete weighing, including both the standard and the object under investigation, occupies ½–¾ hour. So far, the method has been used to study how reduced weight decreases with starvation in amœbæ.

This method has been worked out in the Carlsberg Laboratory, and a full account of the method as well as of the studies (with Dr. H. Holter) on *Chaos chaos* will appear in the *Compt. rend. Lab. Carlsberg, Sér. Chim.*

Distribution of the Total and Acetic Acid-Soluble Phosphate in Soil Profiles having Naturally Free and Impeded Drainage

IN a reconnaissance soil survey of Aberdeenshire, a large and representative collection of soil profiles from a variety of geological parent material types has been made. Pairs of profiles differing in their degree of natural drainage—freely drained, and poorly drained (gleyed) soils—have been taken from a large number of arable fields over a variety of geological areas. Each particular pair of profiles presumably has had the same manurial treatment.

In the routine chemical analysis of these profiles, the percentages of total and acetic-soluble phosphate have been determined, and several facts relating to the phosphate status of these pairs of profiles have appeared.

The freely drained arable profiles have a medium brown crumb-structured A horizon; yellow or yellow-orange, mellow B_1 horizon; greyish-yellow, very indurated and compact B_2 horizon, which merges into the C horizon or parent material. The poorly drained soils have a grey-brown or brownish-grey cloddy A horizon, relatively low in organic matter, on a grey and brown mottled, cloddy gley G horizon.

It has been found that, in arable soils, when a freely drained and a poorly drained soil from the same field are examined: (1) the total phosphate content of the A horizon of the freely drained soil is greater than that of the poorly drained, and that the trend down the profile of the total phosphate generally shows a gradual decrease to the C horizon; (2) the total phosphate content of the poorly drained soil is at its highest value in the A horizon and tends to be lowest beneath the A horizon at the top of the gley horizon; beneath this it gradually rises to the C horizon; (3) the total phosphate in the C horizon of the freely drained soil is generally slightly higher than in the C horizon of the poorly drained soil; (4) the acetic-soluble phosphate in the freely drained soil is usually highest in the indurated B_2 horizon, in which the free silica and sesquioxides are also high; (5) the acetic-soluble phosphate in the poorly drained soil is generally highest in the gley horizon, where the total phosphate is lowest; (6) the rise in the acetic-soluble phosphate in the B_2 horizon of the freely drained soils is not connected with a corresponding rise in the total phosphate content of this layer. The clay content and base-exchange capacity of the indurated horizon are lower than the horizons above and below it.

The content of organic matter in the freely drained soils decreases gradually down the profile, whereas in the poorly drained soils the *A* horizon tends to be lower than that of the freely drained and decreases sharply below this in the gley horizon. The *p*H of the poorly drained soils is generally somewhat higher than that of the freely drained soils. The silica sesquioxide ratios down the poorly drained profiles fluctuate in an erratic manner and alternate with a periodicity from high to low. It is suggested that it is due to the periodicity in fluctuation of the level of the ground-water of these soils.

The high total phosphate in the *A* horizon of the freely drained soil as compared with the parent material suggests that applied phosphate may be accumulated more readily in the unavailable form in the naturally freely drained soils.

The striking reduction in the amount of the total phosphate and the high, readily soluble phosphate in the *G* horizons of the poorly drained soils is possibly related to the reducing conditions. This points to a loss of phosphate in the ground-water from these soils.

These several trends in the phosphate status of soils of different drainage conditions are being investigated.

Vernalization of Sugar Beet

In connexion with L. G. G. Warne's experiments on the vernalization of lettuce reported recently[1], we are able to confirm that the vernalization treatment given after radicle emergence had occurred has no effect on the bolting of sugar beets.

Field experiments were carried out last year near Tirlemont (Belgium) with 'Hilleshög' beets. Several sets of seeds were soaked for seventy-two hours, according to E. Larose and R. Vanderwalle[2], by which time germination had begun and radicles emerged here and there. After soaking, seven sets (III to IX) were held at 2–3° C. during periods varying from ten to seventy days. Two control sets (I and II) were not given the low-temperature treatment; (I) seeds were not soaked, (II) seeds were soaked during seventy-two hours. The nine sets were sown in the open on April 16 (six repetitions of two hundred beets for each set).

Compared with the control sets, the thirty to seventy days vernalized seeds emerged from the soil later, and the growth of the seedlings was seriously delayed during the first six weeks; the differences grew less apparent in June, and after the middle of July all the sets were showing the same development. The beets were harvested on October 24. As appears in the accompanying table, practically no bolting occurred, but there were many missing beets among the fifty, sixty and seventy days vernalized sets. Moreover, the low-temperature treatment showed no effect on the yield of the crop.

These observations confirm Dr. Warne's opinion as to the possibility of avoiding the undesirable influence of natural vernalization on sugar beets and other crop plants by the sowing of already germinated seeds. Further experiments would, of course, be necessary to determine, for each plant, the appropriate soaking conditions of the seeds and the timing of the vernalization treatments.

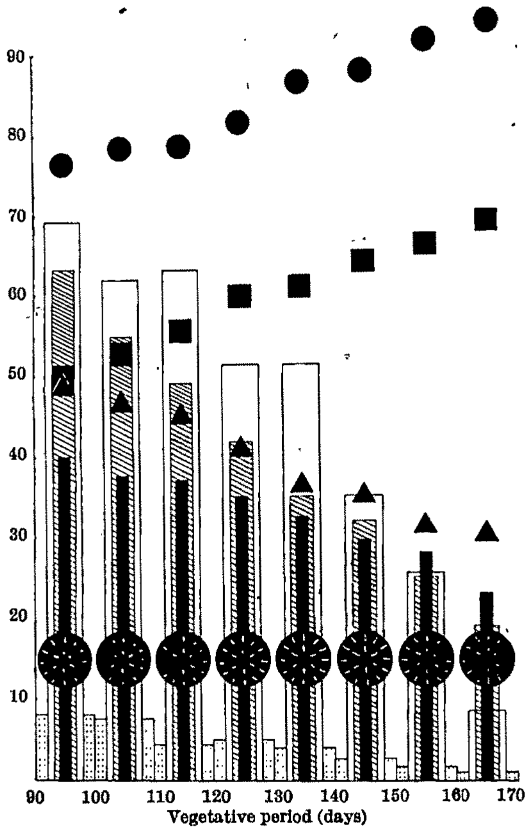
Correlation between Yield of Wheat and Temperature during Ripening of Grain

During the last five years investigations have been undertaken at this Institute for evolving a reliable method for obtaining varieties of wheat best suited to 'dry' as well as irrigated tracts, and also for determining their drought resistance. To achieve this purpose, a large number of exotic and Indian varieties of wheat (260 in all) have been grown on dry and irrigated plots of well-manured land at Delhi, Karnal and Pusa. The Indian varieties used in these experiments were representative of the important wheat-growing tracts of this country with their vegetative period ranging from 90 to 130 days, while the exotic varieties with a range of 90–170 days were representative of the important wheat belts of Canada, the U.S.S.R., Great Britain, Australia and other countries. All these varieties form a part of the large collection of wheat varieties maintained at this Institute.

Growth and harvest data, together with the dates of flowering and ripening of grain, were recorded. As the results appear to have some practical value, a brief preliminary report of the work is given here. It is intended to publish the full details of the work elsewhere. Some of the results are summarized in the accompanying diagram.



EFFECT OF TEMPERATURE ON YIELD OF WHEAT

☐, grain wt. per 10 plants (gm.)
■, 1,000-grain wt. (gm.)
●, mean max. temp. of ripening period
■, „ min. „ „ „ „
▲, „ per cent humidity „
Hatched area, ripening period (days)
Dotted area (ear/tiller) × 10

The full range of the vegetative period is divided into eight classes with a class interval of ten days. The values of grain yield, ripening period, 1,000-kernel weight as well as ear/tiller ratio for each class have been derived by taking the mean of corresponding values for all varieties falling within a class. It will appear that there is a progressive fall in grain yield and 1,000-kernel weight from the early flowering varieties to the late flowering ones. The fall is especially noticeable in the last three classes. Varieties in late-flowering classes require fewer days for grain ripening compared to those in the early ones. Number of ears per plant does not increase in late varieties in spite of heavy tillering, and consequently ear/tiller ratio declines with lateness in flowering. Mean maximum and minimum temperatures as well as mean per cent humidity for each variety were calculated by summing up all the values of the respective climatic factor during the ripening period and dividing by the number of days of the ripening period. Means of all such values for varieties falling within a class have been entered in the diagram. The plumpness of the grain in different classes is indicated in the diagram on the black circular areas.

Total as well as partial correlation coefficients are all very highly significant, with the exception of one case where the partial correlation coefficient $r_{bc.a}$ is non-significant. It is worthy of note that the general trend of results remains the same for dry as well as irrigated crops. This indicates that there is a more pronounced effect of atmospheric drought at least during the ripening period, and that even if the level of moisture in the soil is raised by a late irrigation, its effect on the yield is relatively smaller than that of the adverse climatic factor, namely, the temperature prevailing during the ripening period. This is further supported by the study of indices of resistance to soil and atmospheric drought which are summarized in Table 2.

TABLE 1. TOTAL AND PARTIAL CORRELATION COEFFICIENTS SHOWING RELATIONSHIP BETWEEN (*a*) GRAIN YIELD, (*b*) 1,000-KERNEL WEIGHT, AND (*c*) MEAN MAXIMUM TEMPERATURE OF THE RIPENING PERIOD. *S* = significant at 1 per cent point; *s* = significant at 5 per cent point; *n* = not significant

Nature of crop	Total correlation coefficient	Partial correlation coefficient	Observed value of *t*
Irrigated	r_{ac} = −0·83 to −0·70 r_{ab} = 0·87 to 0·68 r_{bc} = −0·83 to −0·44	$r_{ac.b}$ = −0·60 to −0·27 $r_{ab.c}$ = 0·58 to 0·56 $r_{bc.a}$ = −0·47 to −0·07*n*	39–7 *S* 87–19 *S* 26–0·6 *S*
'Dry'	r_{ac} = −0·81 to −0·68 r_{ab} = 0·88 to 0·64 r_{bc} = −0·89 to −0·54	$r_{ab.c}$ $r_{ac.b}$ = −0·51 to −0·15*s* $r_{ab.c}$ = 0·60 to 0·45 $r_{bc.a}$ = −0·62 to −0·18	32–2 *S* 38–10 *S* 40–3 *S*

TABLE 2. RESISTANCE INDICES

Vegetative period (days)	100	110	120	130	140	150	160	170
Index of resistance to:								
Soil drought	0·56	0·45	0·60	0·56	0·47	0·45	0·47	0·53
Atmospheric drought	1·00	0·94	0·94	0·75	0·67	0·48	0·39	0·16

The index of resistance to soil drought was calculated by dividing the yield of a variety grown on dry land by the corresponding yield of the same variety grown on irrigated land in the same year and in the same locality. This index does not show any significant difference in different flowering classes. The index for resistance to atmospheric drought, on the other hand, which is obtained by dividing individual yields of varieties in each class by the mean yield of the earliest class, shows a progressive decline with lateness in flowering.

Although yield in wheat and other cereals has been correlated with different growth characters, such as 1,000-kernel weight, plumpness, weight of grain per spike, time of flowering, etc.[1,2,4,5,7,9], there is very little experimental evidence to show the effect of temperature on yield. So far as I am aware, Waldron[8] is the only one who has found experimentally a high negative correlation between yield of wheat varieties and the mean maximum temperature of July. It has recently been shown in this laboratory[6] that high temperature during the ripening period of late varieties accelerates the rate of cell division in the developing grain. In late varieties the rate of loss of water from the developing grain is also considerably greater. This shortening of the ripening period appears to be detrimental to processes involved in grain filling, as demonstrated by the progressively falling 1,000-kernel weight and the shrivelled nature of grain resulting in low yield.

This work is an experimental confirmation of the observation, made by Howard[3], that in India early wheats possess an advantage in yield over late ones by virtue of their capacity to avoid high temperatures. It also places the empirical method of selecting wheat varieties so far practised in India on a scientific basis, showing that the selection should be on the correlation of yield and temperature during the ripening period.

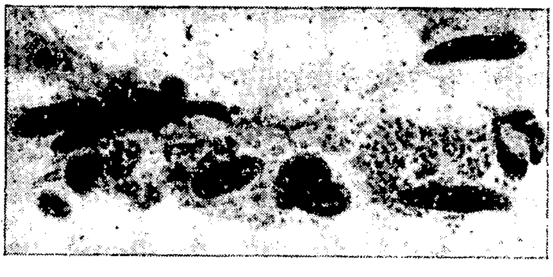
A Hæmosporidian of Bats

DURING the autumn of 1946 a number of bats belonging to ten species were examined for malaria parasites. These included: 39 *Rhinolophus ferrum-equinum*, 18 *Rhinopoma microphyllum*, 5 *Asellia tridens*, 13 *Taphozous nudiventris*, 57 *Myotis myotis*, 18 *Myotis daubentonii*, 17 *Myotis nattererii*, 78 *Pipistrellus kuhlii*, 45 *Miniopterus schreibersii* and 9 *Roussettus ægyptiacus*.

In 10 *Myotis myotis*, 3 *Myotis nattererii* and 35 *Miniopterus schreibersii*, red cells were found to harbour pigmented parasites. All the forms seen were diagnosed as gametocytes in various stages of development. The fully developed gametocyte is round and fills the whole of the parasitized red cell. The rate of infestation varied between single gametocytes in a thick drop up to two or three gametocytes per microscopic field in a thin film. Exflagellation of the microgametocyte was obtained in the wet chamber.

So far, no schizogonic cycle has been found in red blood cells even in splenectomized animals.



SMEAR OF BONE-MARROW FROM *Myotis myotis*

In one *Myotis myotis* intense schizogony was seen in smears of various tissues. Reticulum cells and cells of the granulocyte series of the bone-marrow contained numerous parasites in various stages of schizogony; in tissue smears free schizonts were also found. Wandering and fixed macrophages of the lung, kidney and liver were parasitized to a lesser degree. In one *Myotis nattererii* similar schizogonic forms were also found free in smears of the liver and kidney.

The schizogonic cycle in the tissues resembles in many respects that of *Hæmoproteus columbæ* as described by Aragão.

Myotis myotis, *Myotis nattererii* and *Miniopterus schreibersii* were heavily infested with pupiparous flies of the family Nycteribiidæ belonging to various species not yet fully identified. In one of these, sporozoites were found in the salivary glands.

Investigations up to now do not warrant any final conclusion as to the exact systematic position of these parasites. So far as we know, this is the first instance in which prolific extra-erythrocytic schizogony of a Hæmosporidian with a pigment-producing gametocyte has been found in a mammal.

Fuller details on the evolution of these parasites will be published elsewhere.

This work was carried out with a grant from the Wellcome Research Foundation. We are indebted to Dr. M. Dor for the identification of the bats.

A Sandfly Described in 1691

WE have discovered recently the existence of a description of a sandfly by Phillipo Bonanni[1] published in 1691, together with an interesting plate. So far as we are aware, there is no mention of it in recent literature, and it is unknown to other workers on *Phlebotomus*.

Larrouse[2], in his treatise published in 1921, gives the earliest description of a *Phlebotomus* known to him then as being that of Scopoli[3] in 1786, and since Larrouse's monograph no earlier record seems to have been mentioned. Bonanni's description is of a general character, and he considers his sandfly to be a species of mosquito, which he calls *Sarapico*: "Culex minimus aculeatus Sarapico". He distinctly mentions its nocturnal and blood-sucking habits: "Avidissimus humani sanguinis noctu præcipuse venatur sine sono", and appears to be surprised at the ferocity of the bite which this minute creature is capable of with its short proboscis.

We have not verified its systematic position as yet, but hope to attempt to do so in the near future. As there is no figure of the buccal armature and genital organs, and also on account of recently accepted taxonomic characters, it will prove difficult to relate it to one of the recently described species.

It should be mentioned that Bonanni directs attention to another insect which was sometimes captured together with his sandflies. It appears from the description and figure to be a species of *Pericoma*, a genus closely allied to *Phlebotomus*.

A detailed communication is to appear elsewhere.

QUANTITATIVE CHROMATOGRAPHIC SEPARATIONS OF SYNTHETIC PEPTIDES

By M. JUTISZ and E. LEDERER
Laboratory of Biochemistry, University of Lyons

THE following chromatographic separations of simple peptides have been reported in the last few years: fractionation of arginyl peptides on acid earths[1], partition chromatography of acetyl peptides on columns of silica gel[2], partition of free peptides on columns of starch[3], partition on two-dimensional paper chromatograms of a partial hydrolysate of gramicidin *S* [4] and of peptides of urine[5], and separations of synthetic peptides on columns of carbon by displacement analysis[6].

We now wish to report some simple chromatographic methods capable of separating quantitatively and specifically a complex mixture of peptides and amino-acids into different groups; the separation of each group into its constituents can be realized by paper chromatography or otherwise.

Adsorption of Neutral Peptides on Acid Alumina in 10 per cent Formaldehyde[7,12]

The following table contains the measurements of Dunn and Loshakoff[8] of the apparent acid dissociation constant (*p*K*a'*) of neutral amino-acids and peptides in water and 9 per cent formaldehyde.

TABLE 1

Amino-acid	*p*K*a'* Water	*p*K*a'* 9% Formaldehyde	Peptide	*p*K*a'* Water	*p*K*a'* 9% Formaldehyde
Alanine	9·68	6·96	Glycyl-glycine	8·13	4·27
Valine	9·64	7·47	Di-glycyl-glycine	8·0	4·24
Norleucine	9·77	7·10	Glycyl-leucine	—	4·40
Phenylalanine	9·12	6·80	Alanyl-glycine	7·75	5·52
Glycine	9·60	5·92	Leucyl-glycine	—	5·57
Serine	9·15	5·63	Leucyl-tyrosine	—	5·07

Schramm and Primosigh[9] utilized the more acid *p*K*a'* of glycine and serine in 10 per cent formaldehyde to separate them from the other neutral amino-acids; glycine and serine are quantitatively adsorbed on acid alumina (Wieland[10]) and were eluted with alkali. Later they showed that threonine and cysteine are also adsorbed on alumina in 10 per cent formaldehyde[11].

We have applied the same principle to neutral peptides and found that they are all quantitatively adsorbed on acid alumina; they may be eluted quantitatively by hot water which dissociates the peptide-formaldehyde complex. β-Alanine, which has an —NH_2 group on a primary carbon like glycine, is also adsorbed quantitatively on acid alumina and may so be separated from α-alanine. Table 2 shows the results of some separations of binary mixtures of amino-acids and peptides.

TABLE 2. SEPARATIONS OF BINARY MIXTURES OF AMINO-ACIDS AND PEPTIDES IN 10 PER CENT FORMALDEHYDE

Non-adsorbed amino-acids	% in filtrate (i)	% in filtrate (ii)	Adsorbed substances	% in eluate (i)	% in eluate (ii)
Alanine	99·4		Alanyl-phenylalanine	101·3	100
Alanine	99		Leucyl-glycine	100·5	
Alanine	100	96·4	*β*-Alanine	99·2	
Leucine	100	101·6	Glycyl-leucine	99	
Leucine	100·7		Leucyl-tyrosine	101·2	
Tyrosine	99·2	99	Alanyl-glycine	101·5	
Tryptophane	98		Alanyl-glycine	100·5	

(i), Nitrogen determinations by micro-Kjeldahl; (ii), determinations by known specific methods.

10 gm. of acid alumina[10] are washed in a column of 10 mm. diameter with 300 ml. of water; the *p*H of the last drop of effluent must be about 4·8–4·9 or else separations are not quantitative. After filtering on the column the solution of about 10 mgm. of the mixture of substances in 5 ml. of 10 per cent formaldehyde (*p*H 8·5), one washes the amino-acids into the filtrate with 50 ml. of 10 per cent formaldehyde (*p*H 8·5). Elution of the peptides is obtained by washing the column with 100 ml. of hot water (∼90°).

Adsorption of Glycyl-peptides on Acid Alumina in 1 per cent Formaldehyde[12]

Table 1 shows that glycyl-peptides ($H_2N–CH_2–CONH–CH$*R*$–COOH$) have a more acid *p*K*a'* in 9 per cent formaldehyde than other (alanyl-, leucyl-, etc.) peptides. We have found that in 1 per cent formaldehyde glycyl-peptides are already sufficiently acid to be adsorbed quantitatively on acid alumina, whereas other peptides pass through the column, not being adsorbed. Elution of the glycyl-peptides is easily obtained by washing the column with hot water. The amino-acids glycine, serine, threonine, cysteine and β-alanine, which are adsorbed from 10 per cent formaldehyde solution, are not adsorbed from 1 per cent formaldehyde solution. Table 3 shows some separations of binary mixtures.

TABLE 3. SEPARATIONS OF BINARY MIXTURES OF AMINO-ACIDS AND PEPTIDES IN 1 PER CENT FORMALDEHYDE

Non-adsorbed substance	% in filtrate (i)	% in filtrate (ii)	Adsorbed peptide	% in eluate (i)	% in eluate (ii)
Alanyl-leucine	102		Glycyl-leucine	98·3	99·2
Alanyl-leucine	100		Glycyl-tryptophane	98	100
Leucyl-glycine	100·7		Glycyl-leucine	98·6	
Leucyl-glycine	100		Glycyl-tryptophane	100·5	
Glycocolle	99·6	103	Glycyl-glycine	101·3	
Serine	97·6		Glycyl-tyrosine	100	93

(i), Nitrogen determinations by micro-Kjeldahl; (ii), specific determinations by known methods.

The optimum *p*H for separations in 1 per cent formaldehyde is 3·5 for effluent wash-water; acid alumina prepared according to Wieland[10] can be utilized as it is; the mixture of peptides (10–20 mgm.) dissolved in 5 ml. 1 per cent formaldehyde (*p*H 3·5) is poured on a column of 5 gm. acid alumina (10 mm. diameter); by washing with 50 ml. of 1 per cent formaldehyde, *p*H 3·5, the non-adsorbed substances are washed into the filtrate. Elution of adsorbed glycyl-peptides is obtained with 100 ml. hot water (∼90°).

We suppose that seryl-, threonyl-, cysteyl- and β-alanyl-peptides will behave like the glycyl-peptides.

Adsorption of Aromatic Neutral Peptides on Carbon

Wachtel and Cassidy[13], Tiselius[6], Schramm and Primosigh[9] have studied adsorption of amino-acids on carbon columns, and have observed that the aromatic amino-acids (phenylalanine, tyrosine, tryptophane) are firmly bound. Elution of the adsorbed amino-acids is often difficult and seldom exceeds 85 per cent.

We have found that carbon columns retain quantitatively neutral peptides containing aromatic amino-acids; other neutral peptides containing only aliphatic amino-acids are not adsorbed. Elution is possible with water saturated with ethyl acetate[6,13]; yields attain 95 per cent if the carbon ('Activit *50XP*' [14]) is first purified by boiling in 20 per cent acetic acid and then treated with ephedrin[6]. 1 gm. of 'Activit' can adsorb about 30–50 mgm. of aromatic dipeptides. Table 4 shows some typical separations.

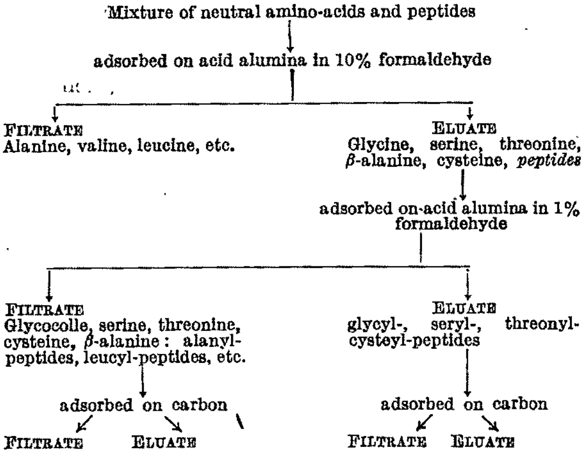
TABLE 4. SEPARATIONS OF BINARY MIXTURES OF ALIPHATIC AND AROMATIC PEPTIDES ON CARBON

Non-adsorbed aliphatic peptides	% in filtrate (i)	Adsorbed aromatic peptides	% in eluate (i)	(ii)
Leucyl-glycine	100·8	Leucyl-tyrosine	96·8	100
Glycyl-leucine	98·3	Glycyl-tyrosine	99·8	100
Alanyl-glycine	99·8	Alanyl-phenylalanine	100·4	99·1

(i), Nitrogen determinations by micro-Kjeldahl; (ii), specific determinations by known colorimetric methods.

0·5 gm. of '*Activit 5OXP*' is boiled for 5 min. with 4 ml. of 20 per cent acetic acid, filtered, washed with 15ml. hot water, then treated in a beaker with 10 ml. water containing 2 mgm. of ephedrine; after shaking for 10 min. the carbon is poured into the column (10 mm. diameter) and washed with 15 ml. water saturated with hydrogen sulphide. The mixture to be separated (20–30 mgm.) in 5 ml. of 5 per cent acetic acid saturated with hydrogen sulphide is filtered on the column, which is then washed with 25 ml. of 5 per cent acetic acid saturated with hydrogen sulphide. Non-adsorbed substances are thus washed into the filtrate. The aromatic peptides are eluted with 125 ml. of water saturated with ethyl acetate and hydrogen sulphide.

By the methods described above a complex mixture of neutral amino-acids and peptides, such as may result from partial hydrolysis of a protein, can be separated into different groups as shown in the following scheme:



Mixture of neutral amino-acids and peptides
adsorbed on acid alumina in 10% formaldehyde
FILTRATE
Alanine, valine, leucine, etc.
ELUATE
Glycine, serine, threonine, β-alanine, cysteine, *peptides*
adsorbed on acid alumina in 1% formaldehyde
FILTRATE
Glycocolle, serine, threonine, cysteine, β-alanine: alanyl-peptides, leucyl-peptides, etc.
ELUATE
glycyl-, seryl-, threonyl-cysteyl-peptides
adsorbed on carbon
FILTRATE
Aliphatic peptides
Example:
Alanyl-glycine
ELUATE
Aromatic peptides
Alanyl-phenylalanine
adsorbed on carbon
FILTRATE
Aliphatic peptides
Glycyl-alanine
ELUATE
Aromatic peptides
Glycyl-phenylalanine

Adsorption of Acid Peptides on Acid Alumina

Preliminary experiments with glutathione and glycyl-glutamic acid show that acid peptides are quantitatively adsorbed on acid alumina, like glutamic and aspartic acid; elution can be obtained either by acid or, better, by alkali.

All these experiments were done with synthetic di- and tri-peptides; there are reasons to believe that the same methods will be applicable to higher peptides.

Acknowledgments are due to Prof. Cl. Fromageot for his interest in this work, to Dr. H. Pénau (UCLAF, Paris) for a research fellowship granted to one of us (M. J.), and to Prof. V. Prelog (Zurich), Dr. M. Guggenheim (Basle), and Dr. C. J. Cavallito (Rensselaer, New York), for various synthetic peptides.

THE TEACHING OF TAXONOMY

A JOINT meeting of the Linnean Society and the Systematics Association was held in the rooms of the former at Burlington House on February 6, when "The Teaching of Taxonomy" was the subject discussed. Sir Clive Forster-Cooper opened the discussion by noting the wide points of view and urging the importance of modern taxonomy. At one time taxonomy was the foremost branch of biology. It then suffered a decline relative to newer aspects and for a long time was considered a blind alley; but a revival of interest is now occurring. There are dangers in speaking too much of the 'professional' taxonomist, but the museum taxonomist is certainly overburdened in the answering of questions for others and has very little time left for research. It becomes a question whether all the wealth of facts and ideas now tending to be incorporated in taxonomy can be brought together in a unified syllabus for teaching in schools and universities. Sir Clive made the suggestion that the Systematics Association should appoint a committee to draw up some sort of guiding rules, of a sufficiently elastic nature, for the benefit of teachers, and to encourage them to teach students taxonomy along desirable lines.

Prof. James Gray considered it would be a pity if taxonomists should look upon their subject as a Cinderella, for though taxonomy is not the sole basis of biology it can play its part like all other branches in the development of the subject. Taxonomy must be seen as one of many points of view. Not more than 10 per cent of students of biology become taxonomists, and the problem for the teacher is how he can convey the taxonomic point of view and the discipline of the subject to the other 90 per cent so that they can carry away something which is to them a matter of intellectual pride. The systematist is to a large degree born such, and works much by general impressions. On the whole, the botanist seems to be more fortunate than the zoologist in having workable keys provided for him, and there is a great need in zoology for simple keys that can be used by students and teachers.

Dr. W. B. Turrill urged that plant taxonomy should be taught because it is indispensable to the proper study of every other branch of botany, provides admirable material for training in observation, concentration, and record keeping; it is the best means by which students can become familiar with the great wealth of form and the extent of combinations and permutations of characters. Much of the time of professional taxonomists would be saved if more botanists were able to carry out a fair proportion of their own determinations and knew when, and when not, to call in the specialist. That taxonomy is not kept to the forefront in schools and colleges may be because it is a subject in which the teacher can be too easily caught out by his students. Dr. Turrill argued that the best way of giving instruction in taxonomy is by practice with material collected by the student himself. Actual practice in the use and making of keys, descriptions, and illustrations has the double advantage of establishing and increasing interest and in laying a solid foundation for discussion on the principles of classification. When the student is acquainted with sufficient factual data he should be helped to grasp the total of underlying principles and generalizations, and aided in giving them logical form. Through the whole of their course students should be made to go out into the field and garden to collect, handle, dissect, and record their findings for actual specimens which they must learn to classify and dissect. In brief, there are decided limits to the possibilities of the direct adequate teaching of taxonomy, but the student can and should be taught to teach himself taxonomy.

Prof. A. R. Clapham pointed out that plant taxonomy is a branch of botany in its own right and is also a tool for other branches. Yet botany has a unity imposed by its materials. The teacher has to aim at training botanists, and all his students should know something of the methods and principles of taxonomy just as those who become taxonomists should know at least a minimum of facts and principles in other branches. Taxonomy is not every man's meat. There must be the right mental outlook and a good appreciation of formal characters and of resemblances and differences, that is, a good visual memory. At the University of Sheffield, Prof. Clapham has no course planned solely for taxonomy, but the subject is united with other subjects such as floral biology, cytogenetics, or ecology. Emphasis is placed on the study of species, and examples are taken from the British flora. Small problems are set which may involve taxonomic studies. Taxonomy as a working tool is taught in the field by the study of quadrats and transects. Every year there are one or two students who are much more competent in taxonomy than are other students. These are encouraged to concentrate on the subject. The highest standards are insisted upon.

Prof. H. Boschma (University of Leyden) was introduced by Prof. de Beer as holding the unique position of professor of taxonomic zoology. Prof. Boschma replied to Prof. Gray that the latter's suggestion that identification of plants is easier than that of animals is not true for all groups in either kingdom. He gave some interesting details of the courses in zoology in Leyden. There are two main examinations. In preparation for the first, systematics is taught in association with anatomy; but for the second examination a special subject is chosen, and only a small percentage of students take systematic zoology. The special student is given material on which to work, is introduced to relevant literature, and then has very largely to investigate for himself. The successful students are the born systematists, and sufficient are selected to fill the vacant posts in museums and other institutions needing specialist taxonomists.

Dr. P. Richards thought that the reputation of taxonomy as a dull subject is due partly to an attempt to teach the results of taxonomy rather than taxonomy as a living branch of research, and partly to academic teaching being too much concerned with the families and larger taxonomic units rather than with species and intra-specific units. The characters of, for example, a family are extremely abstract. He described an experiment tried recently at Cambridge in which every advanced student makes, with some help and guidance, a thorough study of the taxonomy of a single variable species or of two or three closely related species, in the field, the laboratory, and the herbarium. The results have shown that the method is very successful in stimulating interest and in giving insight into the real nature of taxonomy. Dr. Richards also suggested that the teaching of taxonomic botany should not be based entirely on the flowering plants. In particular, mosses and liverworts provide excellent material, available at any time of the year, for the teaching of taxonomy. He also urged the need for a text-book of plant taxonomy covering the whole field. He suggested that the Systematics Association should initiate or encourage the writing of such a book.

Prof. A. E. Trueman referred to the point of view of the palæontologist and to the great difficulties of identification owing to the very great wealth of past life now known. More and more species and genera are having to be accepted. Whether it be studied for applied purposes or as part of the philosophy of biology, all kinds of taxonomic research and training are involved in palæontology.

Prof. A. G. Tansley agreed that a systematist must be born and endowed with a good visual memory. He stressed the importance of students working at individual species rather than being given abstract accounts of families. A student cannot build up a sound taxonomic knowledge unless he gets to know species in the field and herbarium.

Dr. S. P. Wiltshire stressed the need in plant pathology for training in the procedure of identification of fungi. The correct identification of pathogenic fungi is essential in order to make the relevant literature available. Yet many supposedly fully trained mycologists from the universities have never seen the inside of a herbarium packet or looked at the rules of nomenclature.

Mr. A. J. Wilmott said that by the study of one particular example of name change, if sufficiently complicated, all sorts of methods and bases of systematic work can be understood.

Dr. G. S. Carter considered that biology is now part of the schoolboy's *work* and has, therefore, less interest for him. Students should be encouraged to take up the problems of classification of small groups. This would make them realize what a species is.

Prof. I. Manton pointed out that many provincial teaching institutions have no great national collection of plants near at hand. She suggested that the Systematics Association might well arrange a course for precise training in herbarium methods.

Dr. O. W. Richards asked that universities should employ entomologists on their staffs and have entomology recognized as a degree subject.

The president of the Linnean Society, Prof. G. R. de Beer, in summing up the results of the discussion, gave examples of the high cost of a lack of knowledge of taxonomy. It had been clearly shown that there is a wide recognition of the value of taxonomy and that more of it is wanted. When the Linnean Society was founded, taxonomy was the most prominent aspect of biology, and ever since, symposia on taxonomic subjects have been a recurring feature of its meetings. This shows the perennial value of taxonomy as an intellectual discipline. The Society itself is the custodian of important taxonomic collections, and the Council is fully prepared to co-operate in the giving of instruction in taxonomic principles.

FORTHCOMING EVENTS

Wednesday, April 9

INSTITUTE OF PETROLEUM (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. H. Steiner: "Aromatics from Petroleum".

Thursday, April 10

INSTITUTION OF CHEMICAL ENGINEERS (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 11 a.m.—Twenty-fifth Annual Meeting; at 12 noon—Mr. Hugh Griffiths: "Crystallisation".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. C. T. Melling: "Commercial Development of Electricity Supply as a Consumer Service".

ILLUMINATING ENGINEERING SOCIETY, MANCHESTER CENTRE (in the Reynolds Hall, College of Technology, Manchester), at 6 p.m.—Mr. W. J. Wellwood Ferguson: "Lighting in Coal Mines".

ROYAL AERONAUTICAL SOCIETY (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. C. E. Fielding: "A Review of Production Difficulties in Relation to Aircraft Design".

WOMEN'S ENGINEERING SOCIETY, MANCHESTER BRANCH (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Dr. N. H. Searby: "Television".

Wednesday, April 9—Thursday, April 10

FARADAY SOCIETY (in the Chemistry Department, The University, Manchester).—General Discussion on "Electrode Processes".

Wednesday, April 9

At 10 a.m.—General Discussion.

Thursday, April 10

At 10 a.m.—General Discussion.

INSTITUTION OF ELECTRONICS, N.W. ENGLAND SECTION (in the Great Hall, College of Technology, Manchester).—Annual General Meeting and Second Annual Exhibition.

Wednesday, April 9, at 6.30 p.m.
Thursday, April 10, at 2.30 p.m.

MATHEMATICAL ASSOCIATION (at the Polytechnic, 309 Regent Street, London, W.1).—Annual General Meeting.

Wednesday, April 9—Saturday, April 12

PHYSICAL SOCIETY (at Imperial College, Imperial Institute Road, London, S.W.7), at 10 a.m.—Thirty-first Exhibition of Scientific Instruments and Apparatus.

Thursday, April 10—Tuesday, April 15

BRITISH PSYCHOLOGICAL SOCIETY (at the Bergman Österberg Physical Training College, Dartford Heath, Kent).—Annual General Meeting.

Mr. R. J. Bartlett: "Mind" (Presidential Address), at 5 p.m. on April 12.

Friday, April 11

TEXTILE INSTITUTE—(at 16 St. Mary's Parsonage, Manchester), at 1 p.m.—Mr. C. Garrett: "The Bleaching and Subsequent Dyeing of Jute Fabrics".

BIOCHEMICAL SOCIETY (at the Rowett Research Institute, Bucksburn, Aberdeen), at 2.30 p.m.—Scientific Papers and Demonstrations.

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

OIL AND COLOUR CHEMISTS' ASSOCIATION, MANCHESTER SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Annual General Meeting.

PAPER MAKERS' ASSOCIATION, NORTHERN DIVISION (at the Engineers' Club, Albert Square, Manchester), at 7 p.m.—Discussion on "From Press to Reel End".

SHEFFIELD METALLURGICAL ASSOCIATION, MODERN METHODS OF ANALYSIS GROUP (at 198 West Street, Sheffield), at 7 p.m.—Mr. G. Robinson: "Metallurgical Chromatography".

SOCIETY OF DYERS AND COLOURISTS (at St. Enoch Hotel, Glasgow), at 7 p.m.—Dr. G. L. Royer: "The Application of Microscopy to the Textile Field".

Saturday, April 12

BRITISH INTERPLANETARY SOCIETY (at the Science Museum, Exhibition Road, London, S.W.7), at 6 p.m.—Mr. Lionel Gilbert: "Cosmic Rays".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LABORATORY STEWARD (Grade D) IN THE DEPARTMENT OF BOTANY—The Professor of Botany, The University, Leeds 2 (April 8).

SCIENTIFIC OFFICER as ASSISTANT IN THE OPERATIONAL RESEARCH SECTION (University degree in Chemistry, Biology, Physics or Mathematics essential)—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, endorsed 'Operational Research Section' (April 12).

DIRECTOR OF THE SCIENCE DEPARTMENT—The Director, Appointments Department, British Council, 3 Hanover Street, London, W.1 (April 15).

SENIOR LECTURER, and a LECTURER, IN THE DEPARTMENT OF ANATOMY—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (April 15).

LECTURER IN THE DEPARTMENT OF GEOLOGY—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (April 24).

LECTURER with qualifications in Pure Mathematics, a LECTURER with qualifications in Applied Mathematics, and an ASSISTANT LECTURER with qualifications in Pure or Applied Mathematics—The Registrar, The University, Manchester 13 (April 24).

LECTURER (Grade III) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING (Electrotechnics)—The Registrar, The University, Liverpool (April 26).

CHIEF PHARMACIST to the Ministry of Health—The Director of Establishments, Ministry of Health, Whitehall, London, S.W.1 (April 26).

I.C.I. RESEARCH FELLOWSHIPS (3) IN CHEMISTRY or PHYSICS, or some allied subject such as Biochemistry, Colloid Science, Chemotherapy, Pharmacology, Metallurgy or Engineering—The Registrar, The University, Liverpool (April 30).

PROFESSOR OF PATHOLOGY in the Medical School, Dundee, and PATHOLOGIST and CLINICAL PATHOLOGIST to the Dundee Royal Infirmary (associated appointments)—The Secretary, The University, St. Andrews (April 30).

LECTURER IN MATHEMATICS, and a LECTURER IN MATHEMATICAL PHYSICS—The Secretary, Queen's University, Belfast (May 1).

TECHNICIAN in the Dental Hospital of the University of Bristol—The Professor of Pathology, Canynge Hall, Bristol 8 (May 1).

LECTURER IN SOCIAL PSYCHOLOGY—The Registrar, The University, Leeds 2 (May 1).

PROFESSOR OF METALLURGY—The Registrar, University College, Singleton Park, Swansea (May 3).

READERSHIP IN PURE MATHEMATICS tenable at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 13).

LECTURER IN HUMAN PHYSIOLOGY—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (May 15).

METALLURGIST with industrial or research experience of foundry work, a METALLURGIST for independent research work on non-ferrous metal foundry problems, and METALLURGISTS (2) for the Liaison and Technical Service Department—The Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

LABORATORY STEWARD (biology)—The Head of the Department of Chemistry and Biology, The Polytechnic, 309 Regent Street, London, W.1.

ASSISTANT TECHNICAL SECRETARY IN THE METALLURGY DIVISION—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1 (endorsed 'Metallurgy Division').

ASSISTANT BIOCHEMIST at the Courtauld Institute—The Medical School Secretary, Middlesex Hospital, London, W.1.

LECTURER IN GEOGRAPHY, a LECTURER IN PURE MATHEMATICS, a LECTURER IN ORGANIC CHEMISTRY, a LECTURER IN PHYSICS, and an ASSISTANT LECTURER IN CHEMISTRY—The Registrar, University College, Leicester.

TECHNICAL RESEARCH ASSISTANT (well qualified) for nutritional research—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

SENIOR LECTURER IN MATHEMATICS—The Secretary, Royal Technical College, Glasgow.

RESEARCH CHEMIST—The Director of Research, Research Association of British Flour Millers; Cereals Research Station, Old London Road, St. Albans.

TECHNICAL INDEXER on the staff of the Plant and Animal Products Department—The Establishment Officer, Imperial Institute, South Kensington, London, S.W.7.

PHYSICIST with considerable knowledge of rubber technology, for research and development on the engineering applications of rubber, a PHYSICIST to work on fundamental aspects of rubber elasticity, a PHYSICAL CHEMIST to work on the kinetics of oxidation, and an ORGANIC CHEMIST to study the effect of structure on chemical reactivity—The Secretary, British Rubber Producers' Research Association, 19 Fenchurch Street, London, E.C.3.

CHEMIST, a BOTANIST, and an AGRICULTURIST, in the Intelligence Section of the Plant and Animal Products Department—The Establishment Officer, Imperial Institute, South Kensington, London, S.W.7.

CHEMIST or BIOCHEMIST to assist in isolation of substances of biological interest from natural sources—The Professor of Pathology, Sir William Dunn School of Pathology, Oxford.

ANATOMY DISSECTING-ROOM ATTENDANT, and a LABORATORY STEWARD (experienced) with knowledge of physics and laboratory administration—The Secretary, King's College, Strand, London, W.C.2.

METEOROLOGICAL OFFICERS IN MALAYA—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

LABORATORY TECHNICIAN—The Medical Superintendent, St. Luke's Hospital, Middlesbrough.

ATOMIC ENERGY

THE series of talks on atomic energy which the British Broadcasting Corporation arranged during the first week of March in the Home Service Programme and afterwards repeated in the Third Programme have rightly been characterized by Mr. J. B. Priestley as a fine, bold enterprise in public enlightenment. No man of science or thoughtful citizen who has any conception of the implications for mankind of recent discoveries in this field can fail to welcome this effort, and the B.B.C. is to be congratulated further in publishing so promptly in the *Listener* (March 13) the whole series of talks, so that they can be studied at leisure by listeners and also by those who were unable or disinclined to hear the whole series. Delivered by such authorities as Prof. J. D. Cockcroft, Prof. M. L. E. Oliphant, Sir George Thomson, Prof. P. M. S. Blackett, Sir Henry Dale and Sir John Anderson, who have been in one way or another closely associated with these developments, they put before the public quietly but frankly the facts, theories and problems of atomic energy and their main implications for good or ill.

The scientific worker will not expect to find in these talks facts that were not already well known to him. Prof. Cockcroft's account of early experiments, and Prof. Oliphant's description of planning in secret add little to what has already been told in the Smyth Report or the "Statements Relating to the Atomic Bomb". On the military side, Group-Captain G. L. Cheshire recorded his experiences in dropping the bomb, Dr. J. Bronowski described the deep impression made on him when assessing the damage done by the bomb at Hiroshima and Nagasaki, and Sir George Thomson's sombre analysis of the question "Is defence possible ?" is calculated to bring home further, if need be, the dire prospect if mankind allows such bombs to be used again.

Sir George Thomson was able to say little about the contents of the report of the Atomic Energy Commission now before the Security Council; but he and the other speakers said enough to show clearly how great are the obstacles to agreement, and how compelling is the purpose for establishing a strong and comprehensive international system of control and inspection. These talks well display the genuine concern of the scientific worker at the evil use being made of scientific discoveries and at the danger to the free communication of knowledge, in spite of the recommendation of the Atomic Energy Commission itself that safeguards on research in nuclear physics established by the international control agency should not interfere with the prosecution of scientific research or the publication of its results, provided no dangerous purpose or use is involved. Here, too, is well emphasized the way in which preparation for atomic war diverts from peaceful pursuits the resources of man-power and materials which might otherwise so greatly enrich the life of man. We can have atomic energy for peace or for war—but not for both : we can have freedom of science and the peaceful development of atomic energy, or we can have the slow strangling of science by the spread of secrecy and restriction on communication of knowledge in one field after another.

These are choices which mankind must make, deliberately or unconsciously. But there is an even sharper choice and contrast. These talks which the B.B.C. has, with so much public spirit and enterprise, promoted, leave no room for rash optimism that a system of control and inspection by itself will be adequate, however efficient. Inspection and control must be supported by a genuine and resolute will to peace, and a world-wide public opinion which understands what is at stake and is prepared for the sacrifices of national sovereignty which are demanded.

There is no sensationalism in these talks, nor pessimism either, even when Sir George Thomson expresses the opinion that the best defence, and that a poor one, is to evacuate the big cities from the start. The strategic significance of the atomic bomb is analysed by Prof. Cyril Falls, who develops the same idea of dispersal and suggests that, from the national point of view, the best defence is in the first instance ability to retaliate in kind, which still requires the support of traditional armed forces. Prof. Falls adds, however, that in his personal opinion he believes profoundly that the only sure hope for civilization lies in abolishing war altogether.

These opening talks alone should do much to dispel that unconcern with the problem and to quicken the sense of urgency, on the co-operative absence of which in Great Britain Prof. H. C. Urey commented during his recent visit. Even more marked becomes the justification for the whole series, when Prof. Blackett and Sir Henry Dale discuss peaceful uses of atomic energy. It is not Prof. Blackett's lucid discussion of the possibilities of atomic energy for primary power stations, or his suggestion that by 1970 a large proportion of the power in Great Britain will be obtained from atomic energy, that is so significant. It is rather his emphasis that the major difficulty in the realization of such hopes is neither technical nor scientific nor a matter of supply, but rather political and international. "If the major part of the scientific and technical effort available for atomic energy continues to be directed towards the production of more and better bombs, there will be insufficient technical effort and insufficient raw material available to allow the rapid development of industrial power." Even if the bombs are never used, the accumulation of stocks by the armed services of the Great Powers may well check decisively the exploitation of atomic energy for peaceful ends.

From a slightly different outlook, Sir Henry Dale drives home the same point when discussing the application of atomic energy for medicine and research. There is perhaps present in his mind still more the fear of every scientific worker, to which Prof. Oliphant referred in his talk, that the very success of the security restrictions and secrecy which surrounded the work on the development of the atomic bomb will surround the work of the man of science for evermore. Sir Henry asks, "Are men of science to be left to explore these great vistas of new and beneficent knowledge in medicine and elsewhere in peace ? Or will the perversion of these same great gifts of science, and others yet to come, to the wholesale destruction of human life and achievement, bring the civilization, which man has been building since before the dawn of history, crashing down into final ruin ?"

That this is the most important of all the questions facing mankind to-day is supported by Sir George Thomson's following talk on "International Control". Sir George testifies to the profound conviction of men of science, and especially those who played any part in preparing this weapon, of the need for action. However impersonal the scientific attitude may be, and whatever views one may take of the duties of a scientific worker in war, none of us who are physicists, said Sir George, has escaped the feeling of sick horror that what ten years ago seemed a triumph of intellect now adds a supreme danger to our badly shaken civilization. No one is more determined than the physicist that this danger should be turned to a blessing.

Before coming to an extremely lucid review of the work of the Atomic Energy Commission of the proposals known as the Baruch plan, Sir George points out that industrial and military uses are closely interlocked. No real security is achieved, he said, by destroying the bomb case and keeping the plutonium ; destroying the whole thing means destroying the very material most needed for industrial development, and material which must be made again if atomic energy is used at all. The difficulty about the Baruch proposals is that a really rigorous international inspection is essential. It is the only way, he said, in which nations can be convinced that their possible rivals are not secretly preparing weapons they have themselves promised not to prepare ; and that, knowing themselves to be honest, they will not suffer from the sharp practice of others in whom they, perhaps wrongly, have little confidence.

One of the great advantages of the Baruch Plan is that it allows scope for development work and, in fact, runs development work and inspection in double harness ; but when it seemed unlikely that the U.S.S.R. would accept any form of international inspection, the Scientific and Technical Committee was asked to report on the feasibility and the methods of control. This Committee stated definitely that there is nothing on the technical side to make control impossible, and when, while a further systematic study of methods of control was proceeding, the U.S.S.R. accepted, in principle, the idea of an international inspectorate the day-by-day working of which should not be subject to the action of the veto, the easing of the situation encouraged a feeling of optimism. Sir George hopes that the Atomic Energy Commission would be allowed to continue detailed work on the lines of its report to the Security Council of December 31, 1946, and he indicates a number of questions of the highest importance which have yet to be discussed which do not touch that of the veto.

This realistic talk brings home the difficulties with which international control is hedged, but was not too pessimistic, Sir George being convinced that mankind has too much to lose if agreement fails for him not to believe that some way round would be found. Bertrand Russell's talk on the outlook for mankind is perhaps the most sombre of the series. He painted a picture, sober but realistic, of the consequences of failure to reach agreement and of the outcome of atomic war; and he urged, like Sir George Thomson, the adoption of an international system of control of the use of atomic energy as an immense advance towards security. Such control would make possible the peaceful use of the new discoveries without the constant menace of atomic 'Pearl Harbours'; it would demonstrate the possibility of international co-operation and would represent the first step in that limitation of national sovereignty without which nothing can be achieved. Like Prof. Falls, he insists on the impossibility of isolating the question of atomic energy, and emphasized that the real problem is to prevent great wars, for once they have begun no previous agreement will prevent the use of the most terrible weapons available.

Lord Russell based his main appeal on this point and the imperative need for drastic limitation of national sovereignty. He urged that it is the duty of those who realize the implications of modern weapons to devote themselves to a campaign of enlightenment addressed to the peoples of the West and the governments of the East. If mankind can be brought, while there is yet time, to realize that the most elementary motives of self-preservation demand this revolutionary change as regards national sovereignty, he believes a new era of unprecedented happiness and prosperity will almost inevitably result. It is necessary to overcome ancient loyalties, prejudices and deep-rooted suspicions, and to learn to think of mankind as a whole.

Sir John Anderson, in the concluding talk on British interests, does not take quite so grave a view, but his able summing up of the whole series emphasizes once more the impossibility of isolating atomic bombs from other weapons of war. He points out that in the Washington Declaration of November 1945, President Truman, Mr. Attlee and the Prime Minister of Canada pledged themselves to work for the elimination from the armouries of the nations not merely of the atomic bomb but also of all weapons of mass destruction. Like Lord Russell, he stresses the fact that the international body suggested as a means of protecting the world against the military use of atomic energy and encouraging its peaceful use would be something entirely new in human experience.

The ultimate choice before mankind is between a richer and a healthier world, and the virtual extinction of civilized life as we know it. That the choice should thus be put so fairly and squarely before every citizen is no mean contribution to the formation of enlightened public opinion; for it is on such opinion that every democratic government must rely, if it is to frame and pursue a policy of peace and co-operation, with all their implications, which these broadcasts so clearly displayed.

ATOMIC SCIENTISTS' ASSOCIATION

In the United States, the scientific workers concerned in the investigation of nuclear fission in its application to the atomic bomb quickly banded together to make known their views on the scientific, social and international problems raised by the controlled release of atomic energy. In Britain, there were not so many with experience of the subject, and they were scattered up and down the country. Nevertheless, in the early summer of last year, the Atomic Scientists' Association came into being, with the main purpose of providing a forum for discussion of the subject.

In the recent series of broadcast talks on atomic energy, Sir George Thomson referred to the work which the Association is trying to do in Great Britain in impressing on public opinion generally, and on the Government in particular, the critical nature of the position. So far as scientific men themselves are concerned, there can be little question that they are awake to their social responsibilities in this matter, and endeavouring to induce their fellow citizens to consider realistically the new proposals and the departures from previous ideas and practice which the situation demands. That is indeed an encouraging feature of the situation. But the work and aims of the Atomic Scientists' Association deserve indeed to be much more widely known. They go far beyond the technical contributions the Association has already made to the development of an adequate plan of control, either for immediate action or for future operation.

Suggestions to these ends, such as are embodied in the Statement from the Council of Association printed in *Nature* earlier this year (**159**, 47; 1947) come with the greater weight of authority in that the full membership of the Association is limited to men of science with first-hand and specialized knowledge of atomic energy. The Association can thus speak as a body of experts, and this considerably facilitates the furtherance of its aims of investigating and making proposals for the international control of atomic energy in order to assist in the solution of this most pressing problem, and of helping to shape the policy of Britain in all matters relating to atomic energy. For implementing that second aim, and still more that of bringing before the public of Great Britain the true facts about atomic energy and its implications, the necessarily small body of experts requires, however, the support of the much larger body of informed public opinion. This can be provided by enlarging the membership of the Association by the institution of 'associate members', consisting of scientific workers and others who may not have special knowledge of atomic physics but wish to be associated with policy in this field. An appeal for associate members has now been issued over the signature of Prof. N. F. Mott, president of the Association.

The letter in which this appeal is made points out that men of science believe themselves to be fitted to take the lead in these matters because, on the technical aspects of atomic energy, they are the best-informed body. Moreover, those who have been involved in the development of the atomic bomb are deeply concerned about the problems to which it has given rise; before the War men of science took pride in the internationalism of their subject, and they are most anxious again to become a truly international body. To broaden the activities of the Association and especially to expand its publicity efforts, and to make the Association more effective, a large body of associate members is required. Such members will be in touch with the officers of the Association, and will receive free of charge all its publications, including the *News Letter* sent to full members. They can also write to the officers for advice about literature and information about atomic energy, and can express their own views and suggestions about the work of the Association. It is hoped that associate members will contribute generously, as substantial funds are required for effective work by the Association; the annual subscription of one guinea, which should be sent with applications for associate membership to Dr. C. O. Jones, Atomic Scientists' Association, Clarendon Laboratory, Parks Road, Oxford, is regarded as a minimum.

This appeal deserves a generous response, which should be stimulated by the recent broadcasts on atomic energy. Hitherto, the average citizen in Great Britain has had to depend on the views of individuals given sporadically, for guidance in decisions on this important and urgent topic. The extension of the activities of the Atomic Scientists' Association now contemplated should make for the formation of a sound body of public opinion such as is necessary for the guidance of governments in these times.

ANALYSIS AND PROPHECY IN SOCIAL STUDIES

Studies in the Development of Capitalism

By Maurice Dobb. Pp. ix+396. (London: George Routledge and Sons, Ltd., 1946.) 18*s*. net.

Revolution of Environment

By E. A. Gutkind. (International Library of Sociology and Social Reconstruction.) Pp. x+454+74 plates. (London: Kegan Paul and Co., Ltd., 1946.) 30*s*. net.

THOUGH widely different in subject-matter and approach, both these books are attempts to illuminate tendencies of the present by the analysis and synthesis of historical material, and both are concerned with the new opportunities for the development of civilization that now present themselves. In his introduction Dr. Gutkind directs attention to "the discrepancy between social conditions and the economic and technological possibilities" of the modern world, and calls for "an adjustment to new ways of life" by a "revolution of environment" that will produce a more balanced life within and between the nations. Mr. Dobb is concerned primarily with historical analysis, but he, too, has something to say of present trends, and his conclusions are of particular interest at a moment when the problems arising from a policy of 'full employment' and from the economic difficulties of Great Britain are so much in the air.

"Studies in the Development of Capitalism" is a work of synthesis rather than of original research, and Mr. Dobb as an economist is at pains in his introduction to placate both economists and historians who may feel that the book falls between two stools. He confesses, however, to "the obstinate belief that economic analysis only makes sense and can only bear fruit if it is joined to a study of historical development"; and, whatever the reader's view of his arguments and conclusions in detail, the result justifies the belief. In a series of studies Mr. Dobb sketches the development of capitalism from the decline of feudal society to the present day, showing the interplay of the various elements—the growth of the bourgeoisie and of the proletariat, the accumulation of industrial capital and the stimulus of invention and discovery—that together formed the capitalist system in its nineteenth-century heyday. His own definition of capitalism is essentially based on Marxist analysis, entailing as prerequisites of capitalist economy not merely the existence of the profit motive or of production for a distant market, but also the use of labour-power itself as a commodity, bought and sold by a limited class owning the means of production, and controlled by the wage contract. Less narrow definitions, as Mr. Dobb himself admits, would carry the story of capitalism beyond the historical limits he sets himself, but the need, as he sees it, is for "a definition to describe the distinctive economic institutions of the modern world of recent centuries", and as, despite appearances, he disclaims any intention of drawing frontiers between systems in history as "a sharp dividing line", he must be allowed his own definition. Of particular interest is the chapter on the "Growth of the Proletariat", in which Mr. Dobb stresses the point that it was factors other than the mere increase of population that produced the industrial proletariat of the nineteenth century: he neatly quotes J. S. Mill in support of the view that "it is influences affecting the proportion of the population in different social classes with which we are primarily concerned rather than influences affecting the size of the total population".

The general conclusion to which Mr. Dobb's argument leads is that "the economic situation of the hundred years between 1775 and 1875 was no more than a passing phase in the history of Capitalism, product of a set of circumstances which were destined, not only to pass, but in due course to generate their opposite", or, in the words of another writer, Prof. J. R. Hicks, whom he quotes, "nothing else but a vast secular boom". One therefore turns with interest to the last chapter, "The Period Between Two Wars", only to find little light on a confused period and a too ready identification of capitalism with Nazism. But it is, at any rate, clear that a process of development which has been going on for at least several centuries is now taking new forms, and Mr. Dobb sees emerging a form of State capitalism wherein "the focus of attention has radically shifted, and it is on the incentive to Labour—a satisfaction of its claims to a larger share of income, of leisure, of control and to a higher status, as the prerequisite of its co-operation in production—that any discussion of economic policy ultimately turns". Whether that is the final word we cannot yet say: the challenge now is rather to Labour than to Capital.

There is little that is new in Mr. Dobb's material or presentation, nor does he claim originality. But his study of some of the strands that go to make up our modern economic life is an interesting one, though regrettably less readable than it might be. As part of the story of our civilization it suffers perhaps from too narrow an approach. The view of capitalism here presented is likely to prove but a passing phase in a long record of oppression and misery from which man is only now beginning to emerge. Some slight corrections are called for in the book on points of detail: thus, in dealing with the formative seventeenth century Mr. Dobb persistently pre-dates the Commonwealth, and his acquaintance with Clarendon's career seems slight. But these are minor blemishes in a work of this scope.

Dr. Gutkind presents in his "Revolution of Environment" what cannot be called more than a selection of occasional papers. The underlying theme is the interaction of society and environment and the need to plan environment for the improvement of society. Illustrations are taken from China, Russia and the Jesuit settlement in Paraguay, and there is a series of striking plates which unfortunately bear neither numbers nor any definite relation to the text. Much interesting material is presented; but such conclusions as are drawn offer little guidance through current difficulties. Thus a delightful picture of Great Britain "after it has passed through its Revolution of Environment" is presented on p. 94, but it seems remote. Nevertheless, at a time when town and country planning are on the nation's agenda it is well that we should consider what we are aiming at, though perhaps Dr. Gutkind is over-zealous for "new men with new ideas striving towards new goals". New Presbyter may prove to be little more than Old Priest writ large. MAURICE BRUCE

SCIENCE AND CRIME

Forensic Chemistry

By Henry T. F. Rhodes. Second edition revised. Pp. vii + 164. (London: Chapman and Hall, Ltd., 1946.) 15*s*. net.

THE structure of the second edition of this work is essentially that of the earlier edition. In Part 1 of the book the author discusses the evidential value of skin-prints, occupational dust, and the grouping of blood and semen in the identification of the individual. Part 2, dealing with the application of chemical methods to the proof of *corpus delicti*, covers such miscellaneous matters as stains, firearms and explosives, questioned documents, counterfeit money and toxic agents.

Certain sections, notably those on dusts and stains, and on toxic agents, have been very largely re-written. Revision of the former sections has undoubtedly enhanced the usefulness of the book; but the inherent difficulty of treating so vast a subject as forensic chemistry in a volume of this size still reveals itself in a somewhat unbalanced product.

The author emphasizes in his preface that "the subject matter is strictly confined to formally chemical theory and technique". It is difficult to appreciate the insistence upon this rigid segregation of the science, and it appears to have been responsible for several serious omissions. In the short but lucid summary of blood grouping no reference is made, even in passing, to the absorption technique, while in the identification of blood stains, confirmation of the preliminary chemical tests by the precipitin reaction is entirely omitted.

The description of the utilization of micro-methods, and in particular of a micro-form of Stas-Otto procedure, in the examination of dust and debris is a commendable feature. Micro-methods are considered at length in several sections of the book, and some economy in space might well have been effected by the fairly safe assumption that those to whom forensic chemical investigations are entrusted are familiar with the general elementary technique of microanalysis. On the other hand, the spectrograph, that almost indispensable tool of the forensic chemist, is dismissed in three lines with the note that it "is not within the scope of this book", but that "in many cases it is very useful".

The chapter on questioned documents is by far the longest individual section in the book, and treats in an interesting and informative manner not only of the chemical examination of paper, inks and pencils, but also of such subsidiary materials as sealing-wax and adhesives. Sacrifice of the detailed discussion of the molecular structure of tannic acid and iron tannates would not detract from the quality of the chapter.

It is unfortunate that revision of the concluding chapter, on chemical toxicology, has not resulted in a more satisfactory treatment of the subject. Limitation of space inevitably precludes any detailed description of procedure (although arsenic is dealt with at inordinate length), but summaries of the basic processes for the separation of the main groups of poisons should certainly have been included.

The book, which is written throughout in the author's usual excellent literary style, is intended as a "practical guide for those engaged in forensic chemistry", and within its limited confines it provides a valuable introduction to many of the problems confronting the forensic analyst.

G. E. TURFITT

ANIMAL BIOLOGY

Principles of Animal Biology

By Prof. A. Franklin Shull, with the collaboration of Prof. George R. Larue and Alexander G. Ruthven. (McGraw-Hill Publications in the Zoological Sciences.) Sixth edition, second impression. Pp. xi + 425. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 20*s*.

THE necessity for a second impression of the sixth edition of this well-known text-book is sufficient evidence that it meets a widespread demand for a general elementary account of the principles of animal biology. It first appeared in 1920, and various changes have been introduced in successive editions; but those in the present edition are more than usually varied and affect the general plan. It may seem rather surprising to find one of the early chapters devoted to an account of some fundamental physics and chemistry, for apparently in the United States it is possible for a student to graduate in biology without any previous knowledge of those subjects. But in Britain there is a corresponding and probably more widespread ignorance among those graduating in chemistry or physics, who are frequently unacquainted with even the rudiments of any branch of biology.

The first part of the book deals with the functions of protoplasm, cells, cell division (in which the names of the phases of mitosis have been restored), leading on to the basic organisation of the Metazoa. Then follow chapters dealing with the functions of various systems, including the integration of activities by the nervous system and endocrine glands. This comprises a consideration of such diverse subjects as enzymes, photosynthesis, oxidation, muscle action, breathing movements, transfer of respiratory gases, blood composition, clotting, kidney function, vitamins, endocrines, the placenta, and reflex arcs. Reproduction, breeding behaviour and embryonic development are accompanied by a chapter on Mendelian heredity. An account of the general principles of taxonomy is a welcome feature, and there is a summary of the main groups of animals. The chapter on ecology has been enlarged by the addition of marine habitats, and is followed by a good description of the elements of the geographical distribution of animals, of palæontology and of the modification of species. There are a glossary of nearly forty pages and—for the American teacher—a most useful list of 16-mm. motion pictures and film strips that can be used to supplement some of the material in the book. Each film is listed under the first chapter to which it is applicable, and the running time of the film is given together with the addresses of the producers or distributors.

The way of the teacher is certainly made easy by the provision of a book of this nature, which can be thoroughly recommended for an elementary course in animal biology.

The book is well printed on good paper, and the line diagrams for the most part are clear and well chosen. It is all the more regrettable, therefore, that a certain number of very poor and badly reproduced figures should have been included, such as those illustrating the Chordata, and some of the photographs, that of T. H. Huxley being almost unrecognizable.

E. Hindle

STATISTICAL QUALITY CONTROL

Statistical Quality Control

By Prof. Eugene L. Grant. (McGraw-Hill Industrial Organisation and Management Series.) Pp. xii + 563. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 25*s*.

BEFORE the War, quality control methods of the statistical type were to be found in comparatively few industries. The War itself saw them introduced, frequently under Government auspices, into a wide range of industries which had previously never used them; and in consequence there was a sudden load on the available training centres, particularly in the United States, which had any acquaintance with this kind of work. Stanford University bore a full share in the training schemes which were drawn up, and Prof. Grant, who had been lecturing there on the applications of statistical methods to engineering for some seventeen years, found his field of engagements greatly enlarged. His experience as a teacher has now assumed concrete form in this book, which exhibits throughout a most admirable appreciation of the practical aspects of the subject.

The book falls into five parts. The first is introductory and gives the beginner a very clear idea of what statistical quality control can do. Part 2 deals with the control chart for variables based on sample means and ranges; and Part 3 deals similarly with charts for the control of fraction defective. Part 4 discusses the control of quality assurance and acceptance procedures based on single and double sampling techniques.

Thus far the author is on fairly familiar ground, though the abundance of his illustrations and the careful development of the basic ideas will make these sections well worth reading even for the expert. Prof. Grant then turns, in Part 5, to the practical problems of making quality control work, and has some most interesting comments on the cost and organisational factors involved in introducing statistical methods into a factory. The resistance to quality control from the managerial and technical side in some industries has, in fact, to be experienced to be believed. Nearly all the controller's activities "cross the lines of departmental authority", and it is far from easy to persuade the head of one department to increase his expenditure in order to make a larger reduction in costs in other departments. The successful director of a system of quality control has to be not merely a statistician and an engineer, but also a salesman, a psychologist and a diplomat.

The problem of teaching the engineer to think 'probabilistically' is in many ways an easy one. He need not worry about refinements in the theory of inference or torment himself with the question whether probability is a limiting frequency or an undefinable idea. His samples are as large as he likes to make them; probability for him is very much the same thing as relative frequency; and in the course of a very short time he accumulates so much data that he can convince himself that the ordinary laws of probability work in practice whatever their theoretical basis may be. For this reason the engineering world, from Shewhart onwards, has developed a sort of pragmatic frequency theory of probability. It may be difficult to justify logically, but it works. Prof. Grant accordingly introduces probability as a frequency concept, and it is enough for his purposes to take the direct theory as far as the derivation of the binomial and Poisson distributions. He does not require inverse probability at all, although, as he points out, some writers on quality control make an explicit use of Bayes' postulate.

There is a gratuitous footnote on page 112 which would be better omitted. "There seem to be," says the author, "two reasons why the standard error is so frequently misused in applications outside the field of quality control in manufacturing. One reason is that Shewhart's contributions to statistical theory, originally applied in manufacturing, are not so well known as they ought to be to statisticians in other fields. . . . The other reason is that statisticians in other fields are not subject to the immediate check on the accuracy of their predictions which is so common in manufacturing." One can share Prof. Grant's admiration of Dr. Shewhart, one of the pioneers in introducing quality control into industry; but I do not think Dr. Shewhart would claim to have made any contributions to statistical theory or to have taught statisticians anything they did not know about the use of standard errors. Prof. Grant invites the comment that the engineer should stick to his lathe.

But this is the only passage in the whole book to which I would take exception. The work is fluently written and well produced, and may confidently be commended to engineers and statisticians as an excellent account of the subject.

Maurice Kendall

ALEXANDER GRAHAM BELL AND THE INVENTION OF THE TELEPHONE*

By PROF. G. W. O. HOWE

ALEXANDER GRAHAM BELL was born in South Charlotte Street, Edinburgh, on March 3, 1847, the son of Alexander Melville Bell, who was a lecturer in elocution at the University, and whose father, Alexander Bell, was also a prominent teacher of elocution. This Alexander Bell had been a shoemaker in St. Andrews, but had removed to Edinburgh and taken up acting, giving public readings of Shakespeare's plays, and correcting stammering and other defects of speech. He then set up in London as a teacher of elocution.

In 1865, on the death of his father, Melville Bell removed from Edinburgh to London, leaving his Edinburgh pupils and business in the hands of his eldest son, Melville James. Melville Bell was appointed lecturer in elocution at University College. He was probably best known for his work on visible speech, that is, a method of teaching congenital deaf-mutes to speak, and it has been said that Miss Helen Keller is a living monument to his work.

Melville Bell had three sons, of whom Alexander Graham was the second. On leaving Edinburgh High School at the age of fifteen, Alexander Graham went for a year to Elgin as a pupil teacher; he then attended lectures in Greek and Latin at the University of Edinburgh for a year, and at seventeen returned to Elgin as a resident teacher of elocution and music. In 1867 his younger brother died of tuberculosis at the age of nineteen, and Alexander Graham took a post at Bath to be nearer his parents, going the following year to London to be his father's assistant and deputizing for him during his visits to America. He also attended classes in anatomy at University College. Then the elder brother in Edinburgh died suddenly, and as Alexander Graham's health was causing great anxiety, Melville Bell decided to leave London and settle in Brantford, Ontario. This was in 1870, and in the same year he was appointed professor of elocution at Queen's College, Kingston, Ontario. It will be seen that Alexander Graham Bell was born and brought up in an atmosphere of vocal physiology and phonetics. At their father's instigation, he and his elder brother, when schoolboys, had made a model of the mouth and vocal organs in gutta-percha and india-rubber, and operated the lips and tongue while blowing air through it. If it did not speak, it is at least reported to have made a very passable imitation of 'Ma-ma'.

While teaching in Elgin, Alexander tried to determine the pitch of the tones that constitute the various vowel sounds and the resonance pitches of the mouth cavities when shaped to pronounce a given vowel sound. He wrote a forty-page letter to his father about it, and his father consulted his friend Alexander J. Ellis, who later translated Helmholtz's "Sensations of Tone"; Ellis pointed out that Helmholtz had already done the same thing much more thoroughly and had also synthesized the vowel sounds by means of vibrating forks. Bell tried to repeat his experiments, but he confessed afterwards that his knowledge of the laws of electricity was too slight to enable him to understand the explanations given. Ellis lent him the book, but as it was in German, Bell could only study the diagrams and try to interpret them. One of his misunderstandings was very fortunate, for he gathered that Helmholtz had sent vowel sounds by telegraph, and it was two or three years before he found out his mistake. His mind started working on such things as the production of music by a number of electrically maintained forks operated by keys, and the possibility of transmitting the music over wires to a distance where there could be an electrically operated piano. He also thought of transmitting Morse signals by interruption of the musical note. He studied the various systems of telegraphy then in use and became familiar with Morse keys, sounders, etc.

After a year or two in Canada, his health was greatly improved, and he was invited by the Boston Board of Education to investigate the possibility of teaching the children in the school for deaf-mutes to speak by means of his father's system. He spent several months in a number of such schools in New England, and in October 1872 he settled in Boston as a teacher of visible speech, and in the following year was appointed professor of vocal physiology in the School of Oratory of the University of Boston. He was then twenty-six years of age and an elocutionist of the third generation.

Whatever else he might be doing, Bell devoted his spare time to experiments, and in 1874 he had a young instrument maker, Thomas A. Watson, make him a number of electromagnets each with a flat spring armature, one end of the spring being clamped on one pole and the other end free to vibrate over the other pole; those that were to be used as transmitters having make-and-break points like an electric bell. There were six or eight transmitters, all tuned to different frequencies by adjusting the springs and connected to the same number of distant receivers through a single telegraph wire. Each receiver was tuned to its appropriate transmitter and was expected to respond to no other, but to reproduce the dots and dashes by an intermittent tone having a certain pitch. Bell never succeeded in getting this so-called harmonic telegraph to work satisfactorily.

Although he devoted himself whole-heartedly to the development of this harmonic telegraph, he had the transmission of speech always at the back of his mind and discussed it occasionally with his assistant, Watson; but his future father-in-law, who was helping him financially, persuaded him to concentrate on the harmonic telegraph.

In June 1874 he gave an address to a convention of teachers of articulation to the deaf and dumb at Worcester, Mass., and demonstrated to them two instruments with which he did much experimenting. One was the manometric capsule of Koenig, which enabled a deaf person, by watching a sensitive flame in a rotating mirror, to note and try to imitate the wave-forms of the various vowel sounds. The other was Leon Scott's phonautograph, in which the membrane operated a bristle which traced the wave on a moving glass plate coated with lamp black. All this shows clearly that, to Bell, speech and wave-form were almost synonymous.

In February 1875 he went to Washington in connexion with patent applications for multiple telegraphy, and took the opportunity of calling upon Joseph Henry, who was secretary of the Smithsonian Institution, and was then seventy-six. He explained his idea of an articulate telephone; Henry told him that he thought it the germ of a great invention and advised him to work at it and not publish the idea. When Bell said that he felt that he had not the necessary electrical knowledge, Henry replied, "Get it." In a letter to his parents, Bell said, "I cannot tell you how those two words have encouraged me." Little did Henry and Bell dream as they sat talking that they would both, one day, be members of that small group of immortals—Ampère, Volta, Watt, Ohm, Faraday, Maxwell, Joule—whose names are for ever enshrined in the nomenclature of science.

---

* Substance of a commemorative address before the Royal Society of Edinburgh on March 3.

It was on June 2, 1875, that something occurred which altered the whole course of events. Watson was in one room attending to the transmitting reeds, while Bell in an adjacent room put each receiving reed in turn against his ear and adjusted it until it was properly tuned to its respective transmitter. Suddenly Bell rushed in to see what was happening and, as Watson said, "the speaking telephone was born at that moment." What had happened was simply that the make-and-break points of one reed had welded together, and Watson had been plucking the reed to try to restart it, with the result that the sound that Bell heard was entirely changed. He saw at once that the receiver was being actuated, not by an intermittent current, but by an undulatory current in a closed circuit produced by the vibrations of the steel spring over the pole of the electromagnet due to the plucking. He told Watson to make a small drumhead of gold-beater's skin, with the centre joined to the free end of the steel spring by means of a small button of cork, and a mouthpiece over the drumhead. This was made at once and tested the following evening, but the results were not very successful. Although Watson could hear Bell's voice and almost catch the words, it required nine months further experimenting before Watson heard a complete and intelligible sentence. His patent application was filed on February 14, 1876, and the patent was granted on March 7. At that time a complete sentence of intelligible speech had not been transmitted, but a few days later, on March 10, Bell was trying his liquid transmitter in which the diaphragm carried a metallic wire dipping into a cup of acidulated water, and Watson heard the first complete sentence ever transmitted by the telephone. It was "Mr. Watson, come here; I want you." Contrary to the common fallacy that Bell only invented the electromagnetic telephone, claim 4 of his patent specification is for "the method of producing undulations in a continuous voltaic circuit by gradually increasing and diminishing the resistance of the circuit, or by gradually increasing and diminishing the power of the battery, as set forth".

During the summer of 1876 much progress was made, and by October tests were being made between Boston and Cambridge, a distance of two miles. Experiments were made with diaphragms of several feet diameter and with diaphragms as small as that of the human ear, with electromagnets and with permanent magnets of all shapes and sizes, and the present type of receiver gradually emerged. Bell used it both as receiver and transmitter; but it was necessary to speak very loudly in order to obtain satisfactory reception. The liquid transmitter was obviously not very suitable for practical use.

A very interesting coincidence occurred in connexion with Bell's patent application. He did not wish to make the American application until a similar application was lodged in London, and a friend who was going to London took a copy of the application and promised to send Bell a cable as soon as it was lodged. The cable never came and the application remained at the bottom of his friend's trunk. On February 14, 1876, his future father-in-law decided to wait no longer and lodged the application in Washington without consulting Bell. This was a fortunate decision, for an hour or two later on the same day Elisha Gray lodged a caveat which also described a liquid transmitter with an electromagnetic receiver. Another interesting point is that fifteen days after the patent was lodged, Bell altered the wording by substituting "*gradually* increasing and diminishing the resistance", for "*alternately* increasing and diminishing the resistance". This was doubtless intended to emphasize the undulatory nature of the current, which is stressed throughout the specification.

Within a few months Bell exhibited a liquid transmitter as well as the electromagnetic transmitter and receiver at the Philadelphia Centennial Exhibition. One of the judges at this exhibition was Sir William Thomson, afterwards Lord Kelvin, and in his address to the British Association in Glasgow on his return he said: "I heard 'To be, or not to be. There's the rub' through an electric telegraph wire, but scorning monosyllables, the electric articulation rose to higher flights and gave me messages taken at random from the New York newspapers. All this my own ears heard. This, the greatest by far of all the marvels of the electric telegraph, is due to a young countryman of my own, Mr. Graham Bell. Who can but admire the hardihood of invention which devised such very slight means to realize the mathematical conception that, if electricity is to convey all the delicacies of quality which distinguish articulate speech, the strength of the current must vary continuously and as nearly as may be in simple proportion to the velocity of a particle of the air constituting the sound." This was in June 1876, only four months after the lodging of his patent application. Sir William asked for the apparatus to be removed to the Judges' Hall for further tests, as he wanted Lady Thomson to hear it. It is interesting to know that Henry was also one of the judges and reported that Bell's invention was "the greatest marvel hitherto achieved by the telegraph".

The first outdoor telephone line was installed in Boston in 1877, and at that time Bell gave a number of lectures in New York and in most of the large cities of New England, at which demonstrations were given of telephone reproduction of distant singers and speakers. In August of the same year, Bell married and made a trip to England and Scotland. On October 31, 1877, he gave an address in London on "Researches in Electric Telephony", at a special meeting of the Society of Telegraph Engineers (now the Institution of Electrical Engineers). He concluded by saying that conversations had been carried on between New York and Boston, and that Mr. Preece, the engineer-in-chief to the Post Office, had informed him that conversations had been successfully carried on through a submarine cable between Dartmouth and Guernsey. Mr. and Mrs. Bell stayed eighteen months in Britain. Bell was kept busy, lecturing and clearing up the patent muddle caused by his friend's neglect to lodge the application in London before Sir William Thomson's return from America and his publication of all the details.

As an indication of the rapid appreciation of Bell's work and of the remarkable development of the telephone on the commercial side, the Western Union

Telegraph Company declined the offer of Bell's father-in-law to sell all the Bell patents for 100,000 dollars; this was early in 1876. Two years later it was said that the Company would gladly have given 25,000,000 dollars for them.

Bell's idea of using the same instrument as receiver and transmitter proved unsatisfactory because of its lack of sensitivity, and his company soon went over to the use of transmitters of the variable resistance type, acquiring the Blake transmitter in October 1878. In 1879 an agreement was made between the Western Union Company and the Bell Company whereby the latter had the use of the patents of Gray, Edison, Dolbear, and others, owned by the former company, who agreed that Bell was the inventor of the telephone and that his patents were valid and covered such things as transmitters using carbon contacts. But patent litigation went on for many years, the total number of actions involving the Bell patents reaching about six hundred. The great value of Bell's invention can be judged from the number and violence of the attacks made upon it, and its soundness from the complete failure of all the attacks.

On November 24, 1937, a tablet was unveiled on the house in which Alexander Graham Bell was born, and in the address following the function, I mentioned that it might be asked whether the statement that he was the inventor of the telephone was justified. Have not other men been given the credit for the invention? In accounts of early experiments one must not be misled by the use of the word telephone; it was used by Wheatstone and others before Bell was born, for the purely mechanical transmission of sound. The transmission of tones by means of an electric circuit was sometimes referred to as electric telephony; and finally, when speech transmission was attained, it was sometimes distinguished as articulate telephony or speech telephony.

The starting point of all the early experimenters seemed to be the phenomenon of magnetostriction discovered in 1837 by Page, and described by him in *Silliman's Journal* under the title of "The Production of Galvanic Music". If a coil is wound around an iron rod, then the rod emits a sound when the current is switched on and a louder sound when the circuit is suddenly opened. If the current is interrupted at an audible frequency, the rod will emit a musical tone, which can be amplified by mounting the rod on a sounding board. By varying the frequency of the interruptions the rod can be made to 'sing a tune'.

The late Silvanus Thompson wrote a book entitled "Philipp Reis, the Inventor of the Telephone". As I said in 1937, I read and re-read this book, and it removed any doubts which I may have had as to the justification for regarding Bell as the inventor of the telephone. Reis was a school teacher living near Frankfort-on-Main, who devoted years of patient research to the problem of telephony; he read papers and gave demonstrations at Frankfort and other places. After 1864, no further progress appears to have been made; the matter was allowed to drop, and Reis died in 1874. Thompson visited his home and interviewed his widow and others who had known Reis and taken part in his experiments; but there is no reliable evidence that Reis ever succeeded in transmitting a single sentence of intelligible speech. His transmitter was essentially a make-and-break apparatus, capable of transmitting tones and therefore tunes, and very simple vocal sounds. It consisted of a box with a mouthpiece into which one spoke; on the top of the box was a membrane carrying a thin strip of platinum; an arm carried a fine platinum point which was adjusted to touch the platinum strip on the membrane. His receiver was the singing iron rod of Page, mounted on a sounding board, which would respond to the make and break. In the light of our present knowledge—or even of the knowledge of the nature of speech which Bell possessed in 1875—it is obvious that such a make-and-break device could not possibly transmit intelligible speech.

A book entitled "Who Invented the Telephone?", by William Aitken, was published in 1939. It consists in the main of a very crude attack on Bell. It purports to give a reproduction of Bell's patent specification "somewhat abbreviated". On reading it, I wondered if Bell had really made such a muddled statement, but on consulting the actual specification I found it to be crystal clear; the apparent muddle was due entirely to the omission of an essential phrase.

Everyone who came into personal contact with Bell was impressed by his transparent honesty and his readiness to give due credit to other people, so much so that the Bell Company lawyers found it rather disconcerting. On returning from England in 1878, he was so tired of the patent squabbles and the prospect of having to fight unscrupulous rivals, that he decided to give it all up and return to teaching; but Watson, who was sent to Canada for the purpose, persuaded him to return with him to Boston and do his best to defend his patent rights.

For the next year or two he experimented with selenium and the problem of producing and reproducing sound by the agency of light—the photophone as he called it. In 1880 the French Government awarded him the Volta Prize of 50,000 francs which had been established by Napoleon. With this money he established in Washington the Volta Laboratory, and financed experimental work in which he was associated with his cousin, Chichester Bell, and Sumner Tainter. It was this Volta Laboratory Association that made the great advances in the gramophone, replacing Edison's hill-and-dale recording on tin foil by lateral cutting on a wax cylinder and later replacing the cylinder by a disk. When these patents were sold, Bell put his share of 200,000 dollars into the endowment of a Volta Bureau for the increase and diffusion of knowledge relating to the deaf.

In 1885 the Bell family visited Baddeck, in Nova Scotia, and were so pleased with it that Bell gradually acquired land there until he owned a headland which he called Beinn Bhreagh, on which he built a house and a laboratory. This was in 1892. For the remaining thirty years of his life his main interests were sheep breeding and aerial flight. In 1907 he formed an Aerial Experimental Establishment and gathered around him a group of experts. They experimented with man-carrying kites, aeroplanes and hydrofoils.

It was a memorable occasion when in 1915 the coast-to-coast telephone service was opened by Bell in New York and his old assistant Watson in San Francisco, a distance of 3,400 miles.

Bell died at his home in Nova Scotia on August 2, 1922, and was buried on the hilltop at Beinn Bhreagh. The coffin of pine boards was made in the laboratory workshop, and he was dressed in an old homespun working suit with the red button of the Legion of Honour in his buttonhole.

THE ECONOMIC POSITION OF GREAT BRITAIN

THE White Paper "Economic Survey for 1947" (H.M.S.O. Cmd. 7046. 1947. *6d.* net), which has followed the earlier "Statement on the Economic Considerations Affecting Relations between Employers and Workers" and the "Statement Relating to Defence" (Cmd. 7042. H.M.S.O., 1947. *2d.* net), gives a frank and sombre account of Great Britain's economic position. Less exhortative than the earlier one, its chief weakness is the absence of any real indication of the plan of action and the concerted measures by which the Government proposes to meet the danger. None the less, it is a most welcome instrument for educating the people of Great Britain in the true facts of the situation and their individual and collective implications, and every weapon of publicity should be used to bring those facts and implications home to every voter. As the Prime Minister rightly says in the foreword, it is the duty of any democratic Government to take the people frankly into its confidence, however difficult the position of the country may be; and again, "The Government alone cannot achieve success. Everything will depend upon the willing co-operation and determined efforts of all sections of the population. It is essential that all should understand that the maintenance and the raising of the standard of life of the people depends upon the extent to which every individual plays his or her part in contributing to the sum of goods and services available to the nation."

No exception can be taken to the presentation of the facts in the White Paper itself. They are displayed clearly and lucidly and cogently marshalled in support of the argument. There is first a section outlining the nature of economic planning and the considerations upon which democratic planning must be based. Thus early there is the frank warning that if more is required to satisfy any one of the five main national needs—defence, payment for imports, capital equipment and maintenance, personal consumption, and public services—which the twenty million workers in Great Britain, producing goods and services to the value of more than £8,500 millions a year have to satisfy, it can only be at the expense of the others, unless the total amount of work done is increased. If the total resources are reduced by unemployment or by a fall in the output per man-year, less of these requirements can be met.

The White Paper then proceeds to outline the conditions to which economic planning must conform in order to preserve the maximum possible freedom of choice to the individual citizen. Not only must there be regard to our special economic conditions; it is of the first importance that planning in Britain should be as flexible as possible. In avoiding the waste of unemployment, we should not destroy the essential flexibility of our economic life. The Government is seeking to develop a system which comprises an organisation able to gather sufficient knowledge and reliable information to assess the national resources and to formulate the national needs, a set of economic 'budgets' which relates these needs to the country's resources and enables the Government to determine the best use for the resources in the national interest, and methods the combined effect of which enables the Government to influence the use of resources in the desired direction, without interfering with democratic freedoms.

"Resources can be increased by increasing the labour force, or by a bigger output per man-year or by a combination of the two. A reduction in the labour force or a reduction in the output per man-year—by lower efficiency or by shorter hours or increased holidays unaccompanied by a compensating increase in hourly output—reduces the total resources and means that even less of the requirements can be met than before. Planning the allocation of resources between the various national plans is at present a task of deciding which out of a number of claimants must go short—in other words, which are the more important national priorities." While, however, the Government must lay down the economic tasks for the nation and say which things are the most important and what the objectives of policy should be, giving as much information as possible to guide the nation's economic activity and using its powers of economic control to influence the course of development in the right direction, the execution of the plan is a matter for co-operation between Government, industry and the people.

Reviewing next the period July 1945–December 1946, the Statement points out that the defence sector (armed forces and munitions) has been reduced from about 42 per cent of the nation's man-power to less than 10 per cent, and in this re-allocation unemployment in Great Britain never exceeded 2·5 per cent of the insured population, nor, in general, outside the Development Areas, 1·5 per cent. Exports have expanded to 110–115 per cent of the 1938 volume, and in 1946 industrial equipment and maintenance reached a normal pre-war year's work. Homes have been provided, by new building and repair, for nearly 300,000 families, and the way has been cleared for as rapid an expansion in house-building as the material supplies will permit. There has been little change on balance in food consumption; but a considerable expansion in supplies of manufactured goods to the home civilian markets to levels ranging from two-thirds to more than 100 per cent of pre-war years. Although far more plentiful supplies must be available than before the War to remove shortage in the shops, for a large section of the people the present food and clothing rations are more than they could normally afford even in good pre-war years.

In passing to the situation in 1947, the White Paper, like its predecessor, drives home the central fact that we have not enough resources to do all that we want to do, and barely enough to do all we must do. Whether we reckon in man-power, coal, electricity, steel or national production as a whole, to get all we want, production would have to be increased by at least twenty-five per cent. The essential priorities are picked out with brutal frankness: first importance must be attached to payment for imports and to basic industries and services, particularly coal and power. These requirements are then explained and related to the general plan, and the broad conclusion reached that the export target of 140 per cent of 1938 volume by the end of the year is of prime importance. Exports to the western hemisphere (and some European countries, with which we have deficits, namely, Sweden, Switzerland, Portugal) are of particular importance, for they earn dollars or the equivalent and pay for our essential imports from these countries. Close import control must be maintained, particularly of products which come predominantly from the western hemisphere. Home production must be increased along lines which contribute to these policies, agriculture and shipping being of major importance in this connexion. Special reliance, it is considered, should be placed upon a substantial growth of engineering, vehicle, chemical and miscellaneous exports. The labour force in manufacturing industry already employed on orders for export is about 50 per cent above the pre-war level, and is capable of further expansion provided that fuel and power supplies are adequate. These export targets cannot be achieved at all readily and sometimes not at all without reducing production available for the home market.

The basic fact of the position of Great Britain over the next few years is that we must devote at least 25 per cent of our manufacturing capacity to the production of exports; and we need to export more than this if we are to get the imports necessary to raise our standards of living. Equally important is the restoration of the full efficiency and productive power of our basic industries. Here it is urged that the 1947 industrial problem is fundamentally one of coal. We cannot afford to set a lower production target for the year than 200 million tons of coal, and this is barely enough for current use and for stock.

To achieve it the Government proposes to increase the labour force by making the industry attractive enough to draw the necessary number of recruits. Underground miners are to be exempt from call-up to the Forces for the next five years, and the National Union of Mineworkers has agreed to the employment of Poles in the mines. High priority is to be given to all measures which can contribute to increased coal production, such as the production and import of mechanized mining equipment and plant for open-cast coal production. The Government will take all possible measures to secure economy in the use of coal and give high priority to the conversion of engines and plant to oil burning. Drastic measures are to be taken to reduce non-industrial consumption of coal, gas and electricity, but the main emphasis in the coal budget is on increased output per man.

In regard to power, while the immediate crisis arises from lack of coal, even at full capacity the power stations of Great Britain cannot meet the demand, and although high priority is given to the production of new generating plant, some years will be required to make up the arrears. The steel shortage results from lack of imports and shortage of coal, but no serious gap is anticipated in 1947 between the supplies available and the essential needs of the major steel-consuming industries, provided that exports are cut to a minimum. Much re-equipment and maintenance work, however, is urgently demanded on the railways, and restoration of shipping is a major task. The Government's agricultural policy is to switch production from crops for direct human consumption to live-stock and live-stock products, especially pigs and poultry, but the world cereal shortage has delayed this policy. More agricultural workers are required; in the building industry, raw materials are the major obstacle to the building programme. There is just a hint that the output per man-year in this industry is far below the level which should be attained.

Reviewing these industries, the Statement indicates that for 1947 the Government is aiming at a distribution of work between capital equipment and maintenance of 48 per cent for new construction and 52 per cent for plant. The former includes 20 per cent for housing, 6 per cent for new industrial building—a figure which appears to be dangerously low, in view of its bearing on industrial efficiency—and 22 per cent for other building and maintenance, including war damage repairs. The latter is made up of 9 per cent for electricity, gas and Post Office; 4 per cent for roads, bridges, docks, harbours, canals, etc.; 15 per cent for railways, commercial road vehicles, shipping and civil aviation; and 24 per cent for plant for industry, mining and agriculture.

On defence, the White Paper provides for a reduction in the Armed Forces from the December 1946 level of 1,427,000 to 1,087,000 by the end of March 1948, and a fall in the number of workers supplying them. The housing programme is 240,000 new permanent houses and 60,000 temporary houses, and the amount of other capital equipment and maintenance work is to exceed that of a normal pre-war year by at least 15 per cent. Programmes for education, public health and national insurance are to go forward, and a proper degree of efficiency of the public services is to be maintained, with special reference to economy in man-power.

The key to success in reaching these objectives is man-power, and both a larger labour force and a higher output per man-hour are required. Moreover, the present geographical and industrial distribution of the labour force is unsatisfactory. Foreign labour is the only substantial means of increasing our prospective labour force of 18,300,000 men and women at December 1947, and while the Statement points out that the old arguments against foreign labour are no longer valid, it does not show a proper appreciation of the urgency of the situation to suggest that they are especially required for the under-manned industries: it is surely only there that such labour should be at present recruited if there is any meaning in the Government's plan. The Statement indicates that the Government contemplates an additional 100,000 workers from all sources, and sets forth the desirable distribution of the total 18,400,000 workers if its objectives are to be realized. "The size and distribution of the labour force are important, but what ultimately counts is the output which the nation produces. We shall not attain the objectives described without an increase in output per man a year. . . . In the longer view, increased output per man-year is the *only* way to expand production and the standard of living. . . . Increased efficiency in the supply of services is just as important as increased output per man-year in the production of goods. . . . Action which serves to reduce output per man-year in any industry is directly endangering the attainment of these objectives. The nation cannot afford shorter hours of work unless these can be shown to increase output per man-year. Greater leisure is a very desirable thing, but it is not at the moment a prime essential like imported food. It is not as important as coal or clothing or housing."

That is putting it bluntly, and much of it needs to be said at the present time. But it is disconcerting to read also that the Government only now proposes to invite the representative organisations of industry to co-operate with it in an attempt to establish the facts regarding output; or that it "attaches great importance to the introduction of systems of payment and other arrangements which provide the maximum incentive to increase output". For it is on Government action that the claim which the transport, distribution and other services make upon man-power largely depends.

Welcome emphasis is laid on research and development in the White Paper, which in referring to a start on longer-range planning for defence research and development with the constitution of the Defence Research Policy Committee, lays stress on the importance of encouraging scientific research and development at a time when economic considerations must severely limit expenditure on new equipment. Although there is evidence that, with the appointment of Sir Henry Tizard as chairman of the Advisory Council on Scientific Policy, knowledge of developments over the whole field of science will be pooled, to the benefit both of the civilian community and of national defence, there is not the same evidence of close co-operation elsewhere.

The references to the Defence Research Policy Committee are, however, encouraging. Through its close link with the Chiefs of Staff, the Committee will be continuously aware of the latest concepts of strategy and operational thought and will itself be able to influence those concepts by reason of its knowledge of future trends in the field of defence science. The Committee will also study programmes for research and development formulated by the Service and Supply Departments in connexion with the preparation of annual estimates, and it will also have brought before it all problems which arise on the higher organisation of defence research and development, and on the requirements of the Service and Supply Departments for scientific man-power, and also major projects for new establishments.

Such organisation providing for effective co-ordination of effort is the right instrument and condition for securing whole-hearted co-operation. It is essential that a like effort should be made in other fields. Co-operation, as Sir George Schuster has pointed out, is a two-way effort, demanding a lead from the Government as well as response from industry and from the nation. It requires organisation and much more than passive acquiescence in regulations or sporadic demands of the Government from individual interests. Whether or not industrial and trade associations become, as Sir George Schuster suggests, bodies to whom a general strategic task can be entrusted with confidence, to be worked out in close collaboration with the trade unions, no such instrument can be substituted for resolute leadership by the Government.

DEFECTIVE COLOUR VISION IN INDUSTRY

A COMMITTEE of the Colour Group of the Physical Society has performed a valuable task for the benefit of the community in preparing its recent "Report on Defective Colour Vision in Industry"*. It is written in a style which will be readily understandable by non-technical readers. Starting with a clear account of the nature and incidence of defective colour vision, it goes on to describe various colour vision tests, and mentions an almost alarming variety; an interesting chapter deals with colour vision in industry and the Services, from which it appears that there is a strong case for pre-vocational testing and routine examination of the colour vision of school children. A concluding chapter makes a series of recommendations, of which perhaps the most important is that "all children should be tested at school at the age of 13 or over, using one of the approved Confusion Chart Tests". Confusion chart tests are also suggested as suitable for pre-vocational tests for a great variety of industries and trades.

Defective colour vision is found, we are told, in about 8 per cent of the male population, but only in a much smaller percentage of women. Of the males, only about 2 per cent are 'dichromats', a class which can match all hues with an additive mixture of two suitable primary colours, and also would be liable to make the grossest errors in colour matching; but there are many in the remaining 6 per cent who, while not liable to confuse (say) reds and greens under good lighting conditions, nevertheless have inferior powers of colour discrimination and may make substantial mistakes if the light is poor. In this group are found the 'anomalous trichromats' who, while requiring *three* suitable primary colours to match all hues by these primaries combined in suitable proportions, nevertheless do not usually agree with such a match made by a normal person. It is important to realize, as is brought out by the report, that colour-defectiveness exists in many degrees of severity; there is no single condition which can be called 'colour blind'.

While the Services, public transport undertakings, and some industrial organisations prevent the entry of unsuitable persons by adequate tests, there is no consistent public policy in attempting to ensure that colour-defective persons do not become occupational misfits. The report instances the textile trades, drapery, electrical industries, paper-making, and many other cases in which a certain proportion (perhaps 20 per cent in some cases) of the employees must perform operations depending on sensitive colour discrimination. In many cases the matter is left to a kind of natural selection; people who find difficulty avoid such jobs, or they are found to be in difficulties and transferred to alternative posts. The Committee remarks in this connexion: "We have a clear impression that this loss of time and efficiency is by no means small, and that there would be real value, both from employers' and employees' points of view, in ensuring that colour-defective persons did not embark on lines of work where normal colour vision is necessary or highly desirable".

The result of a colour vision test is a matter of prime importance to the individual whose career may depend upon it. While stressing the importance of the elimination of colour-defectives from certain callings, the report proposes that the tests should occur before the individual has developed hopes which must be disappointed. We might add that any person failing should be convinced that justice has been done. While this last point is not neglected in the report, it does not seem to have been given enough weight.

The recommendation for the testing of school children is excellent, and there is no doubt that it should be implemented as soon as possible. There will be some boys who will have already been attracted to the Navy or merchant marine, and will, if colour-defective, have to turn their ambitions elsewhere. The defect is just as important in such a case as an error of refraction, and even if the test occupies five minutes of the time of a trained person, is that really an important objection? It is possible that the teachers, who already nobly carry a great burden of duties besides their normal teaching, might be able to include the first test as part of some instructive and amusing game in the ordinary school curriculum, and this without feeling that colour tests were the 'last straw'; there seems scope here for some invention by an educationist who is prepared to study the problem.

---

* Report on Defective Colour Vision in Industry. By a Committee of the Colour Group. Pp. 52. (London: Physical Society, 1946.) 3*s*. 6*d*. net.

The report speaks in various places of the desirability of having well-printed cards for confusion chart tests, adequate lighting, proper refractive corrections, etc.: but these remarks do not appear adequately to reflect the immense importance which is rightly attached by the public to uniformity and justice in tests of this kind. In regard to one calling, the trade union concerned has taken a most active interest in such matters, and was reputed to go so far as to coach candidates in the tests. Even the school 'screening' tests should be uniform in character and adequately planned; a set of grimy cards, half-seen in a bad light, may make more trouble than they are worth. There are people who misunderstand the objects of such tests, and are capable of purchasing a set of cards for study in an attempt to defeat the examiner. If the screening test should be carefully conducted, this applies even more forcefully to the case of the testing of the doubtful cases classed in the report as Group II*a*. In spite of the convenience and undoubted effectiveness of the confusion chart method, the report leaves one with the impression that there is no guarantee that different sets of cards, even of the same supposed character, will not differ appreciably among themselves. This may not matter for a first screening test, but seems a serious drawback in the case of the decision (often difficult to make) as to whether a candidate is admissible to a particular vocation.

It may be that some means can be found of ensuring that confusion chart methods are properly controlled both in the production of the charts and their condition of use; but in this connexion my own experiences in an attempt to produce a standardized colour vision lantern may be of some interest.

In reviewing 'lantern' colour vision tests for entry to the Royal Navy, Commander Macleod found that there were considerable differences among the actual lanterns employed. A committee of the Medical Research Council, to which I had the honour of being co-opted, proposed to make the Board of Trade lantern test, known and well proved over a long period of time, the basis of a lantern test for the Royal Navy. The new lantern as re-designed, and made by Messrs. Kelvin Bottomley & Baird, Ltd., gives almost exactly the same effects as the Board of Trade lantern, except that perhaps the luminous equality of the lights is somewhat closer. Exact equality is too elusive a fox to chase, but by the helpful co-operation of the National Physical Laboratory and the makers, we were able to formulate a set of tolerances to which all lanterns could be produced, but not without considerable effort and care. A good many lanterns have had to be corrected before they passed the careful tests of the National Physical Laboratory. This lantern is the only one, so far as I know, which is regularly produced to conform to the Laboratory's specifications. This question of guaranteed equality and testing is not mentioned in the section of the report dealing with lantern tests, though it is the essential feature of the new lantern.

I have been at some pains to emphasize this question of uniformity because I feel that the vocational tests in particular are too important to be left to somewhat haphazard methods. The report comments, very justly, that if an electrician is tested by a matching test, using wires having clean coloured wrappings seen in a good light, he may not find the same difficulty that he does in practice when the light is poor and the wrappings dirty or faded. On the other hand, there are all degrees of dimness of light and fading, and it is possible that a person who failed in a supposedly 'realistic' test with one concern might pass in another. This may not matter much in the case of small industrial undertakings, which can please themselves about the tests they employ; but if, for example, entry to the Civil Service depends on a test, it ought to be reasonably uniform. On the bases of their possible standardization, and the satisfaction of the candidates with the tests, 'lanterns' have at present some claim to be considered for tests in cases other than those of mariners and transport workers. Every practical test is, in some degree, arbitrary.

Apart, however, from matters of secondary importance, the report should be of great public service in providing for the first time a clear general picture of the problem, and the lines along which its solution should be attempted. The rewards of success will lie in a small but definite improvement in the efficiency of industry, and (much more important) the avoidance of the disappointment and difficulty which may invade the lives of those who are unfortunate enough to suffer from defective colour vision. It is much to be hoped that the report will be carefully read by all educational authorities and persons concerned with recruitment for industry and the professions. L. C. MARTIN

OBITUARIES

Dame Margaret Tuke, D.B.E.

THE largely attended memorial service in St. Paul's Cathedral on March 11 was a tribute to the memory of a woman who gave the best years of her life to the cause of women's education and who, by her inspiration and leadership, brought Bedford College to the forefront of British university colleges for women.

Dame Margaret Tuke, who died on February 21 at the age of eighty-four, was the daughter of James Hack Tuke, of Hitchin, Herts. She was educated at St. John's, Withdean, Brighton, from which school she proceeded to Newnham College, Cambridge, where she read for the Medieval and Modern Languages Tripos. She was appointed to a lectureship in modern languages at Newnham in 1890 and continued in Cambridge until 1905, in which year she accepted the tutorship to women students and a lectureship in French at University College, Bristol. After two years at Bristol, she was appointed principal of Bedford College for Women, then occupying inadequate buildings in Baker Street, London. During Miss Tuke's tenure of the principalship, the College grew in size and importance, and its academic standing became firmly established. It was moved to its present site in Regent's Park and, largely owing to her initiative and energy, extended its range of studies considerably, especially in the natural sciences. Laboratories for botany, chemistry, geology, physics, physiology and zoology were opened, designed to provide adequate facilities for advanced teaching and research work. Additions were also made to the number of subjects in the Faculty of

Arts for which teaching was provided, and Bedford College became one of the most important as well as the largest of the colleges for women in the universities of Great Britain.

Dame Margaret's services to the University of London were notable. It was only four years after her appointment to Bedford College that she was elected to represent the Faculty of Arts on the University Senate, and she was repeatedly re-elected in this capacity until her retirement in 1929. It was very unusual for the head of a college to be elected by the professors, readers and teachers of a faculty as one of their Senate representatives; but the Faculty of Arts had been quick to recognize the administrative ability of the new principal of Bedford, and to see that she would be a tactful advocate of their views. She was an active member of the Academic Council from 1911 until 1929, and also served on a score or more of Senate committees dealing with a wide range of matters, scholastic and social. Of some of these she served as chairman, notably of the University Scholarships Committee, to the work of which she devoted much time when the annual awards were under consideration. Her views on university matters commanded attention and respect. She was responsive to new ideas and encouraging to the younger generation and to colleagues who desired to see improvements made in courses of study or examinations. For her services to education she was created D.B.E. in 1932. The honorary degree of D.Litt. was conferred upon her by the University of Reading in 1937. She was a fellow of Newnham College, Cambridge, from 1905 until 1936.

Dame Margaret was unassuming in manner and blessed with a quiet charm and a ready smile—sometimes said to be a disarming asset. There are gifts of courtesy and kindness which are always recognized and are particularly valuable in one holding an administrative appointment, for they serve to soften the unavoidable asperities which such an office may involve. Dame Margaret Tuke possessed these gifts in a very special degree, and leaves behind her a memory which is sweet and fragrant—a memory which those who were privileged to know her will always treasure. FRANK HORTON

Prof. P. M. Roxby

PROF. PERCY MAUDE ROXBY, as his second name and surname imply, belonged by descent to families long known for service to our public life, especially in the Church. He was the youngest son of the Rev. H. M. Roxby, vicar of Buckden, Hunts, and it is highly characteristic that he had taken a house at Buckden with a view to retirement there, so deep were his attachments to the rural tradition of England, in spite of all the devotion he had lavished upon the University of Liverpool and its students over a period of forty years.

Born on November 21, 1880, Roxby was educated at Bromsgrove School and Christ Church, Oxford, to which he went with an open scholarship in history. He followed this up by gaining the Gladstone Memorial Prize in 1902 and a first-class in modern history in 1903. After graduation, he studied under Prof. A. J. Herbertson, then recently settled in Oxford as head of the Geography Department. Before he had completed his projected scheme, the University of Liverpool inquired for someone to teach geography, and Herbertson sent Roxby to begin what was to be a great life-work as a teacher. After various preliminary stages he was given a full lectureship with the responsibility for geography in the University of Liverpool in 1908. He was awarded the Albert Kahn Travelling Fellowship in 1912 and visited the United States, India and China, beginning in connexion with the last-named what became a life-long attachment and devotion. In 1917 a new chair of geography was given to Liverpool in recognition of Roxby's work, and he held the professorship until 1944.

Roxby's welcome to foreign students in his department brought him notable recruits, including some like Prof. Chang from China and Profs. Amer, Awad, Huzayyin and others from Egypt. He was given leave to act as a member of the China Education Commission in 1921 and, with this added experience of the East, he wrote valuable articles to help teachers and students to understand and interpret China. In 1930 he was invited to act for a year as visiting professor in the Egyptian University at Cairo, where some of his students were implanting his tradition. In the same year he became president of the Geographical Section of the British Association for the Advancement of Science, and his address was a notable plea for the humanist approach to geography.

Under such a vital teacher, the friend of all his students, the Geography Department at Liverpool grew and became one of the acknowledged sources of strength of the University. In addition to lectures, discussions, and help with essays and theses, Roxby gave his time without stint to his students and their problems, personal as well as scientific. He also spent perhaps too much of his time and strength on geographical, educational and international study groups up and down the country without thought of fee or reward. His position as an acknowledged leader of efforts for international understanding became clear as the years passed, and he devoted much thought to committees promoting cultural relations with China and Chinese universities. This ceaseless activity perhaps lessened his output of printed work, but he contributed articles on China to the "Encyclopædia Britannica" and to various reviews, and this culminated in his editing of the Naval Intelligence Handbook on China printed for official use during the 1939–45 war period. It is greatly to be hoped that this monumental work, to which he contributed so much, may soon be made available for general use.

During the War, Roxby's school of geography was to a large extent evacuated from Liverpool to Harlech, and Roxby became for a while responsible for the part of the University of Liverpool installed in that beautiful mountain region, which made a strong appeal to him and led him to encourage students before and after graduation to concern themselves with studies of Wales. If, however, China, Egypt, Lancashire, East Anglia and Wales held his special interest, as a stream of publications by his students indicates, his sympathies were universal, and all superiority complexes were alien to his open mind, which yet maintained a strong loyalty to his own origins.

In 1944 the British Council invited Roxby to become its chief representative in China, and this led him to anticipate his retirement from the University of Liverpool, where he had for so long been an outstanding and beloved member of the professorial staff. He had married in 1941 Miss M. P. Howden, lecturer in history in the University, and with Mrs.

of water in all three phases, the vertical velocity and the turbulent transfer of heat. Some of these factors have never been established inside clouds. Others can only be measured with great difficulty. Much further research is required.

The experiments are part of the programme of the Council for Scientific and Industrial Research, Commonwealth of Australia, in which the Divisions of Physics and Radiophysics are collaborating. We wish to acknowledge the work of Messrs. Harper and Kemp of the Division of Physics in making laboratory experiments which provided data for the full-scale tests. We wish also to make acknowledgment to the crews of No. 82 Wing, Royal Australian Air Force, who were responsible for the flying, to Mr. Heffernan who took part in most of the flights, and to Dr. E. G. Bowen, Chief of the Division of Radiophysics, for his enthusiastic support.

TOXIC ORGANO-LEAD COMPOUNDS

By Dr. H. McCOMBIE

AND

Dr. B. C. SAUNDERS

University Chemical Laboratory, Cambridge

THIS work began in Cambridge in 1939 with the original purpose of preparing compounds of the type PbR_4 which might be toxic by inhalation. It should be noted that, at that time, supplies of arsenic in Great Britain were very much reduced, whereas lead was readily available. Compounds which we contemplated preparing were $(C_2H_5)_2Pb(CH_2CH = CH_2)_2$, $(C_2H_5)_2Pb(CH_2CH_2Cl)_2$ and $Pb(CH_2CH_2Cl)_4$, etc. As an intermediate, it was necessary to prepare triethyl lead chloride $(C_2H_5)_3PbCl$ in quantity, and one of us (B. C. S.), while working with this compound, developed the symptoms of a severe attack of influenza, which, however, wore off at night and returned during the day. The compound was therefore tested for sternutatory properties, and found to produce, at a concentration of one part in a million, an atmosphere in which respiration was difficult.

This discovery then gave a great impetus to the preparation of triethyl lead salts. The original intention of preparing substituted plumbanes was postponed, and the preparation and detailed examination of trialkyl lead compounds were then undertaken. Several hundred compounds were prepared, many of which were new. They were tested as potential sternutators at Cambridge, and reports on these compounds were submitted by us to the Ministry of Supply during the years 1940–41. These reports were also made available to American workers.

It was found that passing reference had been made to the irritant properties of certain trialkyl lead salts by earlier investigators, for example, Krause and Pohland[1]. Gilman and Robinson[2] had noted that sneezing was caused by dust containing triethyl lead salts. No systematic attempt, however, had ever been made to correlate potency with the nature of the constituent groupings, and no compound of high sternutatory power had been recorded. In the present work, emphasis was placed on the production of substances which had the following characteristics: (i) ease of preparation, (ii) reasonable stability, (iii) strong sternutatory action.

A full account of the methods of preparation will be given in the appropriate journals later. Many of the compounds were easily obtained in a highly crystalline pure condition, and have not deteriorated on being stored for several years.

Physiological Examination

Examination of the physiological action of these compounds on ourselves and members of the team was carried out in a glass-walled chamber of 10 c.m. capacity. The substance under test was dissolved in a suitable solvent, and dispersed in the chamber by means of a spray operated by compressed air. Suitably placed fans ensured, so far as possible, an even distribution of the material in the atmosphere inside the chamber. The human observers, four in number, entered the chamber by an air-lock as soon as spraying was complete. The times which then elapsed before irritation occurred in the nose, throat, chest, and gums were noted. Unless the substance proved to be intolerable, the observers stayed in the chamber for 10 minutes. From the data thus compiled, a toxicity rating for a given concentration could be allotted to each compound.

The first concentration to be tried was 1 molecule of the substance in 10,000,000 molecules of air, that is, about 15 mgm. of organo-lead compound were actually dispersed in the chamber. The required amount was dissolved in about 15 ml. of solvent (usually alcohol). For certain of the more potent substances, tests were carried out at concentrations of 1 : 25,000,000.

Triethyl lead chloride, $(C_2H_5)_3PbCl$, was taken as an arbitrary standard, and all other compounds were put into various categories in comparison with this standard. Thus, triethyl lead monochloroacetate, triethyl lead monobromoacetate, triethyl lead cyanate were found to produce effects similar to those produced by triethyl lead chloride at the same molecular concentration[3,4]. The following were examples of triethyl lead salts which were superior as sternutators to triethyl lead chloride:

triethyl lead acetate;
" " cyanide;
" " crotonate;
" " *iso*-valerate;
triethyl lead *p*-toluene sulphonate;
" " thiocyanate;
" " β-chloropropionate.

Certain triethyl lead compounds, for example, triethyl lead selenocyanide, were slightly inferior in their sternutatory effect to the standard triethyl lead chloride.

All trimethyl lead salts (for example, $(CH_3)_3PbCl$, $(CH_3)_3PbO.CO.CH_2Cl$, $(CH_3)_3Pb.O.CO.CH_2CH_2CH(CH_3)_2$) were markedly inferior, irrespective of the acid radical, to all salts of the triethyl lead series. In fact, all trimethyl lead salts produced atmospheres which caused only very mild discomfort at a concentration of 1 part in a million.

Tri-*n*-propyl Lead Salts

Regarding homologues above the triethyl series, we definitely established[3,4,5,6] that derivatives of tri-*n*-propyl lead were without exception markedly more effective than the corresponding compounds of the triethyl lead series. A falling off of potency was, however, noted in the tri-*n*-butyl series, and these compounds were always inferior to the corresponding compounds in the tri-*n*-propyl series, but usually superior to compounds of the triethyl lead series. Tri-*iso*butyl lead salts were also usually inferior to tri-*n*-propyl lead salts.

Of the numerous tri-*n*-propyl lead salts prepared and examined the following may be mentioned:

tri-*n*-propyl lead acetate;
,, ,, bromoacetate
,, ,, iodoacetate;
,, ,, trichloroacetate
,, ,, β-chloropropionate;
tri-*n*-propyl lead *n*-butyrate;
,, ,, *iso*-valerate
,, ,, acrylate;
,, ,, *o*-toluene sulphonate;
,, ,, *p*-toluene sulphonate.

Of the above, tri-*n*-propyl lead acrylate[7,8] was the most potent.

Examples of tri-*n*-butyl lead salts and tri-*iso*butyl lead salts which were superior to triethyl lead chloride in respect of sternutatory properties were:

tri-*n*-butyl lead chloride
,, ,, acetate;
,, ,, bromoacetate;
,, ,, iodoacetate;
,, ,, trichloroacetate;
,, ,, propionate
tri-*n*-butyl lead β-chloropropionate;
,, ,, crotonate;
tri-*iso*butyl lead chloride;
,, ,, acetate;
,, ,, butyrate;
,, ,, *p*-toluene sulphonate.

Dialkyl Lead Salts

We found that, without exception, diethyl lead salts (for example, diethyl lead dichloride $(C_2H_5)_2PbCl_2$) were almost devoid of sternutatory properties. This absence of sternutatory power was independent of the acid radical, for diethyl lead dichloride, dithiocyanate, dibenzoate, di-3 : 5-dinitrobenzoate[6] were all equally ineffective. Even in the *n*-propyl series, the di-*n*-propyl lead salts were found to possess extremely feeble sternutatory properties in spite of the fact that the *n*-propyl radical enhanced potency so markedly in the tri-*n*-propyl lead series.

A New Method for Preparing Diethyl Lead Salts

Triethyl lead salts are readily prepared by neutralizing a solution of triethyl lead hydroxide with the appropriate acid[3]:

$$(C_2H_5)_3PbOH + CH_3CH{:}CHCOOH = (C_2H_5)_3PbO.CO.CH{:}CH.CH_3 + H_2O.$$

When a plumbane is treated with a monobasic acid and silica gel, it has been found that, in some instances, the trialkyl lead salt is produced, whereas in other cases the dialkyl lead salt is formed; for example:

$$(C_2H_5)_4Pb + CH_3COOH = (C_2H_5)_3Pb.O.CO.CH_3 + C_2H_6$$
$$(C_2H_5)_4Pb + 2C_6H_5COOH = (C_2H_5)_2Pb(O.CO.C_6H_5)_2 + 2C_2H_6.$$

It is not always quite clear what governs this difference, although in some cases the strength of the acid seems to be one of the controlling factors[7]. Very frequently the analyses of the two types of salts are close, and an independent method of preparing the diethyl lead salts was obviously essential in order to establish definitely their identity.

In 1940 we showed[3] that moist sulphur dioxide reacted with lead tetraethyl producing *diethyl lead sulphite*, $(C_2H_5)_2PbSO_3$. Later, we discovered that this compound reacted smoothly with a number of acids producing diethyl lead salts:

$$(C_2H_5)_2PbSO_3 + 2CH_2ClCOOH = (C_2H_5)_2Pb(O.CO.CH_2Cl)_2 + SO_2 + H_2O.$$

The compound prepared in this way was different from the compound obtained by the action of chloroacetic acid on lead tetraethyl, and this second compound was identical with the product obtained by the neutralization of triethyl lead hydroxide by chloroacetic acid.

Before leaving dialkyl lead salts, mention should be made of the disproportionation of diethyl lead di-monochloroacetate[7], which we found to proceed in hot aqueous solution as follows:

$$2(C_2H_5)_2Pb(OCOCH_2Cl)_2 = (C_2H_5)_3PbOCOCH_2Cl + Pb(O.CO.CH_2Cl)_2 + ClCH_2COOC_2H_5.$$

Di-*n*-propyl lead diacetate behaved similarly. In view of this facile disproportionation, it is rather surprising that dialkyl lead salts are so ineffective as sternutators.

New Types of Trialkyl Lead Compounds

In addition to the simple trialkyl lead salts mentioned above, we also directed our attention to the synthesis and examination of new types of organo lead compounds[3,5], such as triethyl lead phthalimide  $(C_2H_5)_3PbN\langle{}^{CO}_{CO}\rangle C_6H_4$, triethyl lead ethyl sulphide, $(C_2H_5)_3PbSC_2H_5$, and triethyl lead phenyl sulphide $(C_2H_5)_3PbSC_6H_5$. The first of these compounds is a solid. The sulphides are liquids soluble in non-polar solvents and prepared from triethyl lead hydroxide and the corresponding mercaptan. Triethyl lead ethyl sulphide can be distilled under reduced pressure and possesses an odour resembling that of horseradish. All three possessed sternutatory properties similar to that shown by triethyl lead chloride. Tri-*n*-propyl lead phthalimide[5] was also prepared and, in accordance with expectation, was found to be more potent than triethyl lead phthalimide.

Sulphonamides Containing Lead

In October 1940 we prepared[5,6] a new and interesting type of compound, namely, triethyl lead *p*-toluene sulphonamide, $CH_3C_6H_4SO_2NHPb(C_2H_5)_3$. This highly crystalline compound, recrystallizable from benzene, was obtained in 73 per cent yield by heating the sodium derivative of *p*-toluene sulphonamide with triethyl lead chloride in alcoholic solution:

$$CH_3C_6H_4SO_2NHNa + ClPb(C_2H_5)_3 = CH_3C_6H_4SO_2NHPb(C_2H_5)_3 + NaCl.$$

It was found to be the best lead sternutator examined up to that time, and was intolerable at a concentration of 1 in 10,000,000.

This led to an extensive investigation of this and related compounds, and we later showed[7] that a very simple and satisfactory method of preparation consisted of mixing, in the cold, alcoholic solutions of *p*-toluene sulphonamide and of triethyl lead hydroxide, and then adding water to precipitate the substituted sulphonamide. An almost pure product was obtained even before recrystallization, and the yield was 80 per cent.

$$CH_3C_6H_4SO_2NH_2 + (C_2H_5)_3PbOH = CH_3C_6H_4SO_2NHPb(C_2H_5)_3 + H_2O.$$

In accordance with expectation, tri-*n*-propyl lead *p*-toluene sulphonamide was more potent than the triethyl compound. Similarly, tri-*n*-propyl lead benzene sulphonamide (which was obtained in 93 per cent yield from tri-*n*-propyl lead hydroxide) was a powerful sternutator, and at a concentration of 1 part in 10^7 all observers were forced to leave the chamber at the end of 40 sec.[6]. In addition to its sternutatory effect, this compound produced a pronounced irritation on the fingers and faces of some of the workers who were concerned with its prepara-

Roxby he went out to China in 1945, making plans to help Chinese colleagues in educational and other fields to rehabilitate their cultural life after the dislocation due to so many years of war. Roxby was no westernizer; he loved Chinese thought and Chinese art, and at the same time felt deeply the problem of Chinese rural poverty. One may say that he carried on at least two life-works, one for geographical thought in Great Britain, and especially at the University of Liverpool, and one for and in China. His work for Egypt was scarcely less. His students have spread far and wide, and much of his thought is included in their published work, which habitually refers to him as the source from which they have derived their inspiration. His colleagues in other universities found his selfless co-operation a great support and encouragement, and his help to the Geographical Association through many years is gratefully acknowledged. H. J. FLEURE

WE regret to announce the following deaths:

Prof. V. M. Goldschmidt, For.Mem.R.S., formerly professor of geology and mineralogy in the University of Oslo, on March 20.

Sir Halford Mackinder, P.C., sometime director of the London School of Economics and formerly professor of geography in the University of London, on March 6, aged eighty-six.

Prof. B. A. McSwiney, F.R.S., professor of physiology, Sherrington School of Physiology, St. Thomas's Hospital, London, on March 8, aged fifty-two.

Dr. Walter Ramsden, senior fellow of Pembroke College, Oxford, and emeritus professor of biochemistry in the University of Liverpool, on March 26, aged seventy-eight.

Dr. Alexander Scott, F.R.S., formerly director of scientific research at the British Museum, on March 10, aged ninety-three.

NEWS and VIEWS

Astrophysics at Cambridge: Prof. F. J. M. Stratton, O.B.E., F.R.S.

PROF. F. J. M. STRATTON retires from the chair of astrophysics at Cambridge on September 30. Thus will end an official connexion with the Solar Physics Observatory which dates back to 1909. In that year he was appointed assistant in astrophysics at the Newall Telescope, Cambridge Observatory, while in 1913, when the astronomical work at South Kensington was fused with that of the Newall Telescope under the name of the Solar Physics Observatory, he became assistant director to Prof. H. F. Newall. After the First World War, in which he served with distinction in the Royal Engineers, Stratton was forced by the pressure of his College duties to resign his official post at the Observatory. His research, however, was still carried on from there, and on the retirement of Newall in 1928 Stratton was appointed to the chair of astrophysics and to the directorship of the Observatory. Through his efforts, aided by those of happily chosen successive assistant directors, the Solar Physics Observatory has become to-day, it will be generally agreed, the leading centre for astrophysical research in Great Britain and the training ground for astronomers from many lands.

Prof. Stratton's own researches have covered a wide field, ranging from problems in gravitational and positional astronomy to investigations in astrophysics. He is best known, however, for his work on novæ—initiated by his brilliant discovery of A-type and B-type absorption lines simultaneously appearing in the spectrum of Nova Geminorum II, each type with its own velocity displacement, and culminating in his work on Nova Herculis 1934 and the magnificent atlas of its spectra. He has been an assiduous observer of solar eclipses, and the ultra-violet spectra secured by C. R. Davidson and him of the solar chromosphere at Sumatra in 1926, one of the few occasions on which he has experienced clear skies, have clarified many problems in solar physics. Those who know Prof. Stratton best expect that official retirement will be the signal for a fresh burst of activity, and they look forward to further research and to his beneficent presence at international meetings of astronomers for many years to come.

Dr. R. O. Redman, F.R.S.

DR. R. O. REDMAN, chief assistant at the Radcliffe Observatory, Pretoria, has been appointed professor of astrophysics and director of the Observatories of the University of Cambridge on the retirement of Prof. F. J. M. Stratton. A Sheepshanks Exhibitioner and Isaac Newton Student at Cambridge, he spent part of his time as a student at the Dominion Astrophysical Observatory, Victoria, under Prof. J. S. Plaskett. His work there on the galactic rotation of late-type stars led to his return to Cambridge as assistant director of the Solar Physics Observatory and fellow of St. John's College. His experience with the 72-inch Victoria reflector made him an obvious choice as chief assistant to Dr. Knox Shaw when the Radcliffe Observatory moved from Oxford to Pretoria to complete for the southern sky the work of the Victoria telescope in the northern hemisphere. A series of unhappy delays has so far prevented the Radcliffe Observer and his staff from getting the 74-inch mirror with which the programme was to have been carried out, and Dr. Redman returns with some of his plans unfulfilled. But he has from his days at Victoria, Cambridge, and Pretoria a good volume of first-class work to his credit, mainly in the spheres of photometry and spectrophotometry. With close attention to the instrumental conditions essential to success, he has made very careful studies of the contours of Fraunhofer lines both at the centre of the sun's disk and on the limb, of chromospheric lines as seen at a total eclipse and of the absorption lines at different stages of eclipse of one component of a binary star. He has been a member of four eclipse expeditions, in 1927, 1932, 1936 and 1940. In 1940 he was favoured with fine weather, and secured some valuable spectrographic observations: the high temperature, 30,000°, which he found for the chromosphere and the strength of the weak Fraunhofer lines at the extreme limb of the sun are results which are not yet fully understood. His direct photometry includes work on the Andromeda and other nebulæ and on the use of the Fabry method in stellar photometry. He is at present co-operating with Dr. Stoy of the Cape Observatory on standard stellar magnitudes for the southern sky.

Scientific Civil Service: Promotion of Individual Research Workers

It will be recalled that in the Government White Paper on the Scientific Civil Service (Cmd. 6679) provision was made for the creation of special posts above the level of 'principal scientific officer' to provide for the promotion of individual research men of exceptional quality who would not necessarily have administrative responsibility. Such posts were to be additional to normal departmental complements. Departments were to be invited to nominate members of their staff for appointment to such posts, and these nominations were to be considered first by the Interdepartmental Scientific Panel, which would make recommendations on them to the Treasury. The first appointments under this scheme have now been authorized for the undermentioned members of the Scientific Civil Service, who have been promoted to the grade of 'senior principal scientific officer' (basic salary scale £1,200–1,400) with effect from January 1, 1947. This is the first fruit of what is intended to be an annual review.

J. W. Barnes (Ministry of Supply), a research engineer engaged in the more fundamental aspects of gyroscopic techniques and the design of aircraft equipment. Dr. J. Bronowski (Ministry of Works), author of numerous papers in algebraic geometry; engaged in mathematical and statistical investigations connected with structure of industry, with special application to the building industries. H. L. Cox (Department of Scientific and Industrial Research), an authority on structural problems in aircraft; has made notable contributions to the simplification of engineering research problems by mathematical treatment. Dr. G. E. R. Deacon (Admiralty), a physical chemist who has specialized in oceanography; has taken part in several "Discovery" expeditions to the Antarctic; elected a fellow of the Royal Society in 1944. S. B. Gates (Ministry of Supply), engaged on aerodynamic research with special reference to the stability and control characteristics of aircraft. Dr. J. A. Lovern (Department of Scientific and Industrial Research), known for his fundamental research on the fats of fish and other aquatic animals; has had wide experience of technological problems relating to the handling and processing of fish. J. Morris (Ministry of Supply), an applied mathematician specializing on structural and vibration engineering problems in aircraft. H. B. Squire (Ministry of Supply), an applied mathematician in the field of theoretical aerodynamics, with special reference to problems of supersonic flight, fluid motion and helicopter stability. Dr. W. S. Stiles (Department of Scientific and Industrial Research), an authority on problems of vision with special reference to the sensitivity of different retinal areas to light of various colours, and the efficiency of different parts of the pupil. B. Sykes (Ministry of Supply), a research engineer engaged in the more fundamental aspects of design of aircraft instruments; has made noted contributions to the predictor gun sights of aircraft. Dr. A. M. Turing (Department of Scientific and Industrial Research), author of an important paper "On Computable Numbers" (*Proc. London Math. Soc.*, 1937) which contained the basic idea of the automatic computing machine now being developed at the National Physical Laboratory. Dr. A. M. Uttley (Ministry of Supply), who was earlier engaged in research on visual perception, and more recently on a variety of electronic researches including R.A.F. training equipment, servo mechanisms and astro navigation. Dr. W. H. J. Vernon (Department of Scientific and Industrial Research), a leading authority on the corrosion of metals. Dr. D. Williams (Ministry of Supply), a research engineer and applied mathematician in the field of structures of aircraft.

Further Education

It is peculiarly appropriate that the Turnstile Press, Ltd. (10 Great Turnstile, London, W.C.1), should announce for publication in April the first number of a new educational monthly entitled *Further Education.* The Ministry of Education is now taking active measures to ensure that local education authorities, acting in the closest association with industry, the universities and voluntary organisations, will meet the varied educational needs of adolescents and adults. It has already assured local education authorities that it will encourage experiments, stimulate initiative and foster developments. At the same time, it must be recognized that a repetition of past mistakes will only be avoided, and the maximum opportunity afforded to men and women everywhere to achieve maturity of outlook and a richer leisure, if all engaged in further education can share experiences and contribute their own ideas to the common pool. It is this need which *Further Education* hopes to meet. The first number will include articles on the organisation of further education, the problem of the young worker in industry, the future of discussion groups, the art of listening, commentaries on films, music and radio and book reviews. The editor is Mr. John Mackay-Mure. All subscriptions received before April 30 will be accepted at the reduced rate of fifteen shillings per annum.

Blundell's School Science Society

The educational value of school science societies deserves to be more fully appreciated, and their possibilities as training-grounds for young scientific workers merit wider recognition. For not only do the activities of these societies extend beyond the limitations of routine class-room teaching, they provide conditions under which individual interest can arise and develop as a matter of spontaneous, personal growth; and genuine, personal interest is one of the most important factors making for success in science. At the same time, lectures by visiting speakers enable members to come into contact with persons of some eminence in the fields of research and applied science, and so to learn something of their personality, outlook and achievements. Valuable training is also given to those young scientific workers who themselves deliver lectures, write up reports or prepare exhibits. In the field of biology, if such societies do no more than encourage members to extend their basic acquaintance with plant and animal types, they would be serving a useful purpose. Usually, however, a certain amount of more advanced field work is also undertaken. One notes a tendency to concentrate on ecological studies, which, with beginners, do not always yield very clear results, in contrast to such fields of interest as animal behaviour, seed dispersal, population studies, and applied biology, particularly in relation to agriculture, which provide opportunities for promising work by young observers, carried out at odd times and with little apparatus.

The above points come out clearly in the *Magazine of the Science Society of Blundell's School, Tiverton,* to the first number of which we extend a welcome. As its editors, Mr. W. H. Dowdeswell and Dr. M. Ashby, point out, the issue is nearly all taken up with records of biological observations, although the interests of the more exact sciences are not being overlooked. The magazine records the presentation to Blundell's School of the Rippon collection of butterflies and moths, which is rich in local and migrant specimens as well as in unusual, mutant forms. M. A. Lyne contributes a list of butterflies found in the Tiverton area in 1946; the season, however, was late, dull and wet. There is also a report on an expedition by the Society to Winsford Hill, Exmoor, which led to suggestive contrasts between the fauna and flora of moorland country and those found lower down. Of the botanical studies, a survey of the plant communities on areas of chalk, clay and sand, by R. Champion, is of distinct promise, and a similar one on the flora beneath an oak tree canopy, by O. H. D. Portsmouth, is a conscientious piece of work. In his investigation of animal life in a sea pool, both resident and temporary, R. Honey shows a clear grasp of the main ecological factors concerned, and so does C. D. Weeks in his report on the fauna of a swiftly flowing stream. A study of the food of the wood-pigeon in the Camborne–Redruth area, by J. Williams, produces telling evidence of the destructiveness to farm crops of these birds, while a similar study of the food of the stoat and its effects on other animal life in the north-west Mendips, by S. T. G. Butterworth, is interesting, less for the findings which emerge than from the amount of careful observation which he must have put into it. A further paper on weeds on school lawns, by J. C. Newell-Price, extends interest to applied biology, but stops short of detailed discussion of the ecology of weeds or of their eradication. Altogether, these reports bear evidence of original and independent investigations being carried out by young scientific workers in many different fields, well worthy of recognition and encouragement. Blundell's has always enjoyed a good reputation for scientific work and training; its new *Magazine* will certainly enhance this.

X-Ray Diffraction Index for Identification of Materials

THE "Index of X-ray Diffraction Data" and its first Supplement, published by the American Society for Testing Materials, have been of considerable use in many industrial and other laboratories for the identification of unknown substances. The Supplement was based largely on data edited in Great Britain under the auspices of the Institute of Physics. The preparation of another Supplement has now begun, and the co-operation of all who use powder photographs is invited. Although the main purpose of the Supplement will be to include new substances, new data on substances already in the "Index" will be welcomed. Many of the older data were obtained with short X-rays (such as those from molybdenum) or with small-diameter cameras (such as 5·7 cm.), so that in some cases low-order lines were missed, and in others lines of nearly equal spacing were not resolved. New data obtained with longer X-rays (copper or longer) and larger-diameter cameras (9 cm. or more) are very desirable for these substances. X-ray workers who are able to help by supplying data for new substances, or data that they believe to be more reliable for substances already in the "Index", or corrections of mistakes, or references to work published in periodicals that do not enjoy a wide circulation in Great Britain, are invited to communicate with Dr. A. J. C. Wilson, Physics Department, University College, Cardiff.

Research at the Bermuda Biological Station

THE Bermuda Biological Station for Research has received from the American Philosophical Society a grant of 6,000 dollars for the period of three years, 1947–49, to be used for research fellowships at the Station. Applications should be forwarded to Dr. Dugald E. S. Brown, Director, Biological Station, St. George's, Bermuda. Applicants should state the nature of the intended research and the expected length of stay at the Station.

During the next few years the scientific programme of the Station will be centred around the physiology of marine organisms. To this end laboratories of physiology, biochemistry, and biophysics are being constructed and adequate facilities provided for the collection and maintenance of a wide variety of marine organisms. When the reconstruction is completed, seventeen laboratories will be available to investigators and, in addition, several rooms for workers not requiring the usual laboratory facilities. By June of this year there will be living accommodations for twenty-four workers.

Physical Society's Exhibition

THE thirty-first Exhibition of Scientific Instruments and Apparatus, organised by the Physical Society, will be held during April 9–12 at the Imperial College of Science and Technology, London. Discourses will be delivered each evening at 6.15 (and repeated at 8.15 if necessary) as follows: "Recent Infra-red Developments", by Dr. R. Lee (Admiralty Research Laboratory, Teddington); "Automatic and Manual Position Control Systems", by Prof. A. Porter (Military College of Science, Shrivenham); "Recent Advances in Optical Science", by Mr. B. K. Johnson (Imperial College); "Recent Developments in Air Photography", by Mr. G. C. Brock (Royal Aircraft Establishment, South Farnborough). Films will be shown on each of the four days: "Kelvin, Master of Measurement", by permission of Messrs. Kelvin Bottomley and Baird, Ltd., and Marine Instruments, Ltd.; "Applications of Kinematography in Science", by the British Kinematograph Society; "Time-Lapse Photographs of the Whole Sky", by Kodak, Ltd., Research Laboratories; "Phase-contrast Microscopy of the Development of Sperm Cells of the Grasshopper", by Kodak, Ltd., Research Laboratories. On account of the fuel and power situation, it will not be possible to produce the Catalogue in time for the Exhibition; an 8-page list of exhibitors (with stand numbers) will be available, and the full Catalogue will follow in due course. Admission to the Exhibition is by ticket, 10 a.m.–1 p.m. and 2 p.m.–9 p.m. daily.

Conference on Pulverized Fuel

A CONFERENCE covering the preparation and utilization of pulverized fuel has been arranged under the auspices of the Institute of Fuel and will be held at Harrogate during June 3–6. Some fifty papers are being contributed from users, manufacturers and research organisations, and contributions are expected from Australia, France, Holland, Germany, South Africa and the United States. All papers will be available in the form of a book, so that the sessions will be devoted to discussions, following opening surveys by the chairmen, which will be published later with summaries of the discussions. Further particulars can be obtained from the Pulverized Fuel Conference Committee, Institute of Fuel, 18 Devonshire Street, London, W.1.

University of London: Appointments

THE following appointments in the University of London have been announced:

Dr. C. A. Coulson has been appointed to the University chair of theoretical physics tenable at King's College as from October 1, 1947. During 1928–38 he was a fellow of Trinity College, Cambridge, and later senior lecturer in applied mathematics at Dundee. Since 1945 he has been a College lecturer in mathematics at University College, Oxford, and I.C.I. research fellow in chemistry at the Physical Chemical Laboratory, Oxford.

Dr. E. T. C. Spooner has been appointed to the University chair of bacteriology and immunology tenable at the London School of Hygiene and Tropical Medicine as from October 1, 1947. Since 1931 he has been demonstrator and afterwards lecturer in pathology at Clare College, Cambridge, of which he is a fellow and tutor. During 1940–43 he worked for the Medical Research Council.

Dr. R. M. S. Thompson has been appointed to the University chair of chemical pathology tenable at Guy's Hospital Medical School as from October 1, 1947. In 1938 he was Gillson research scholar in pathology at the Society of Apothecaries in London, and since that date has been fellow and tutor of University College, Oxford, and demonstrator in biochemistry at Oxford. During the War years he was attached to the Chemical Defence Research Department of the Ministry of Supply.

Dr. H. Grüneberg has been appointed to the University readership in genetics tenable at University College as from October 1, 1946. Since 1938 he has held the Moseley research studentship of the Royal Society.

Dr. J. F. Kirkaldy has been appointed to the University readership in geology tenable at Queen Mary College as from October 1, 1947. During 1929–33 he was demonstrator in geology and geography at King's College; later he was assistant lecturer in geology and geography at University College, after which he returned to King's College and was made lecturer in geology and geography in 1939. In the same year he entered the Meteorological Office, and in 1943 took a commission in the Meteorological Section of the R.A.F.V.R.

The title of reader has been conferred on the following in respect of the posts they already hold: Dr. Charlotte M. Fleming, Institute of Education (education); Dr. B. J. Lloyd Evans, University College (mechanical engineering); Dr. D. W. G. Style, King's College (chemistry).

Agricultural Scholarships

THE Ministry of Agriculture and Fisheries invites applications for ten senior scholarships, tenable at university departments of agriculture, or agricultural colleges, for degree or diploma courses, or at veterinary colleges for courses in veterinary science; six extended junior scholarships (for those who have already held junior awards); and sixty junior scholarships, tenable at farm institutes or similar institutions, for courses not exceeding one year in duration. The scholarships are open to the sons and daughters of agricultural workers and to persons who are themselves *bona fide* workers in agriculture. The method of selection is by interview. Candidates for senior or junior scholarships must have attained the age of 17 and 16 years respectively by September 30, 1947. Full information concerning the scheme and forms of application may be obtained from the Secretary of the Ministry, Block 4, Bickenhall Mansions, Baker Street, London, W.1, or from the education offices of County Councils. The latest date for submitting completed applications is April 30.

Announcements

THE Society of Foresters of Great Britain has presented a medal to Sir Roy Lister Robinson, chairman of the Forestry Commission, in recognition of his outstanding services to British forestry. Sir Roy Robinson was the first president of the Society, and this is the first award of its kind. It has been announced that Sir Roy is retiring from the office of director-general of forestry in Great Britain.

SIR JOHN LENNARD-JONES, Plummer professor of theoretical chemistry in the University of Cambridge and chief scientific adviser to the Ministry of Supply, has been appointed chairman of the Advisory Council on Scientific Research and Technical Development, Ministry of Supply, in succession to Sir Frank Heath, who has retired after serving almost from the inception of the Council early in the War.

DR. E. DELPORTE, director of the Royal Observatory of Belgium, Uccle, and Prof. Carl Störmer, professor of mathematics in the University of Oslo, have been elected *Correspondants* of the Section of Astronomy of the Paris Academy of Sciences.

THE annual general meeting of the Mathematical Association will be held at the Polytechnic, Regent Street, London, during April 9–10. The meeting includes discussions on visual aids in the teaching of mathematics and on a unified course in mathematics in secondary schools.

THE following officers were elected at the annual general meeting of the Royal Photographic Society: *President*, F. J. Tritton; *Vice-Presidents*, Percy W. Harris and L. V. Chilton. *Ordinary Members of Council*, Marcus Adams, J. Allan Cash, R. J. Cox, R. N. Haile, R. C. L. Herdson, T. Midgley Illingworth, J. D. Johnston, S. D. Jouhar, Mrs. R. Maingot, H. S. Newcombe, Anthony Peacock, Oliver G. Pike, S. Schofield, D. A. Spencer and G. C. Weston.

THE following have been elected officers for 1947 of the Royal Society of South Africa: *President*, Prof. R. S. Adamson, professor of botany in the University of Cape Town; *Secretary*, A. J. H. Goodwin, University of Cape Town; *Treasurer*, J. G. Rose; *Editor*, Dr. A. L. du Toit; *Librarian*, Dr. E. Newbery; *Members of Council*, Prof. M. R. Drennan, Dr. P. J. du Toit, W. E. Isaac, Dr. J. Jackson, Prof. R. W. James, R. F. Lawrence, Dr. J. V. L. Rennie, Prof. B. F. J. Schonland, Prof. F. Walker, C. L. Wicht.

THE first edition of "British Chemicals and their Manufacturers" to be published after 1939 was issued by the Association of Chemical Manufacturers, 166 Piccadilly, London, W.1, in November 1946. This includes up-to-date information on the manufacturers of all types of chemicals, and also covers the publication "Directory of British Fine Chemicals" (1940), which is merged in the present single volume. A copy will be sent gratis to any *bona fide* inquirer, on application to the Association.

Plant Carbonic Anhydrase

In contrast to the wealth of information concerning carbonic anhydrase in the animal kingdom, there have been few reports of the occurrence of this enzyme in the plant kingdom[1]. It seemed desirable, therefore, briefly to describe the following observations made in the course of work on the enzyme in animal tissues.

Activity tests carried out on aqueous extracts by means of the boat method[2] have revealed a widespread occurrence of carbonic anhydrase in the leaves of flowering plants, including, for example, all cultivated Brassicas, wallflower, peach, cucumber, grapefruit, spinach, *Bunias orientale, Stellaria media, Melilotus altissima* and *Chenopodium album*. Roots of those species investigated showed no carbonic anhydrase, though a small but distinct activity was found in extracts of nodules of French beans (as well as in the leaves). There were also numerous species in which no activity could be detected in the leaves. However, in several of these apparently negative cases, for example lettuce, potato and sugar beet, carbonic anhydrase could be clearly demonstrated when the leaves were ground and extracted with dilute (0·01 *M*) solutions of cysteine (sugar beet, Fig. 1). Moreover, many of the plants which yielded active aqueous extracts showed higher activity when extracted with cysteine solutions (*Tropæolum*, Fig. 1).

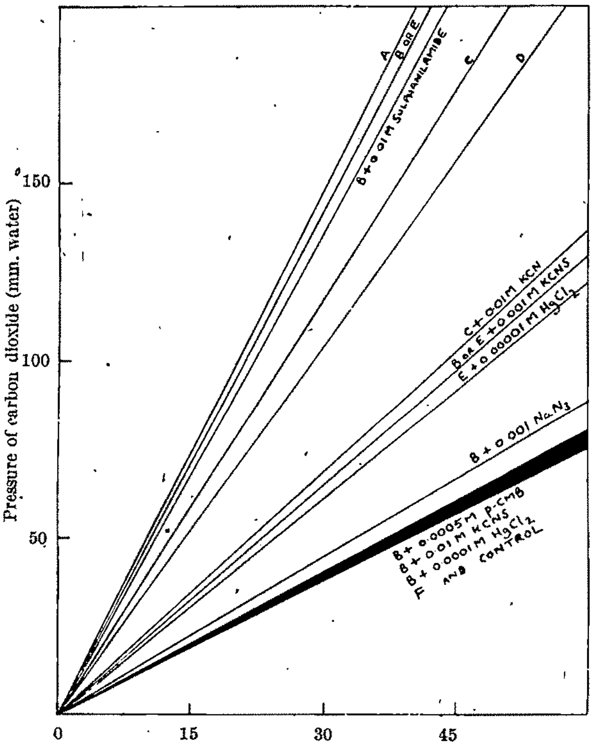

Fig. 1. Rate of output of carbon dioxide at 4·5° C. after mixing 2 ml. bicarbonate solution and 2 ml. phosphate buffer alone (control), and in presence of 0·2 ml. of various leaf extracts (*A, B, C, D, E, F*), showing the effect of several inhibitors (*p*-CMB = *p*-chloromercuribenzoate). 2 gm. of fresh leaf were ground and the suspension filtered to give 10 ml. extract; *A, Tropæolum majus*, 0·01 *M* cysteine extract, and *C*, aqueous extract; *B*, grapefruit, aqueous extract; *D*, sugar beet, cysteine extract, and *F*, aqueous extract; *E*, parsley, aqueous extract

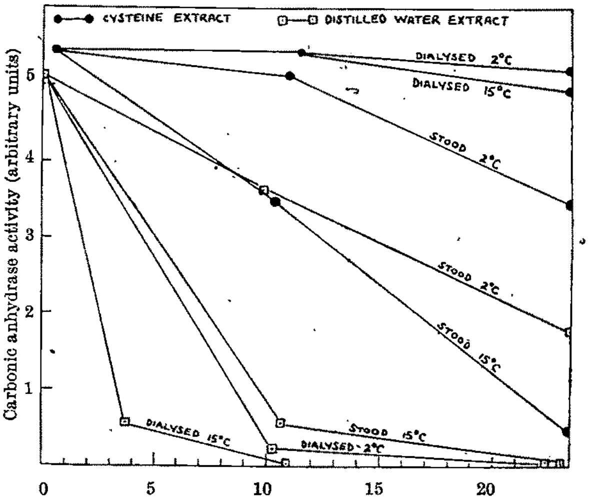

Fig. 2. Effect of ageing and dialysis at 2° C. and 15° C. on carbonic anhydrase activity of leaf extracts of *Tropæolum majus*; aqueous extracts dialysed against glass-distilled water, 0·01 *M* cysteine extracts dialysed against 0·01 *M* cysteine

Generally on standing or on dialysis the aqueous extracts lost enzyme activity quite rapidly; but in *Tropæolum*, for example, cysteine extracts showed only very slight loss after standing for 24 hours at 2° C. or after dialysis against cysteine under these conditions (Fig. 2). This seems to indicate a much greater dependence on SH groups than is the case in animal carbonic anhydrase. Further evidence for this conclusion comes from the fact that 0·0005 *M* *p*-chloromercuribenzoate or iodosobenzoate, regarded as fairly specific SH inactivators, inhibit the plant enzyme in whole leaf extracts more strongly than they inhibit the animal enzyme in highly purified solution. On the other hand, both are strongly inhibited by mercuric chloride, a less specific reagent.

Apart from more marked SH requirements, plant carbonic anhydrase differs from the animal enzyme in several respects: (*a*) The activity in plant sources is generally lower than that in animal sources, an average figure being 1 E.U. per 20 mgm. fresh leaf (determined at 15° C.) compared with 1 E.U. per c.mm. ox blood[2]. (*b*) Sulphanilamide, a specific inhibitor of animal carbonic anhydrase[3], has little or no effect on the leaf enzyme; yet it will completely inhibit animal carbonic anhydrase added to the leaf extracts. A small anhydrase activity observed in intact cells from two cultures of *Chlorella* was, however, completely inhibited by 0·0005 *M* sulphanilamide. (*c*) Cyanide and azide inhibit the plant enzyme, but only in rather high concentrations; thiocyanate inhibits the two enzymes to an approximately equal extent. It must be remembered, however, that comparisons have been made between whole leaf extracts and purified solutions of animal carbonic anhydrase. In all cases the enzyme activity was destroyed after two minutes in a boiling water bath.

All attempts to study the distribution of the plant enzyme in the cell have indicated that, at least in leaf extracts, carbonic anhydrase is absent from the chloroplasts. The latter were separated by centrifugation from glucose-phosphate-buffer extracts and then either re-suspended in glucose buffer where most remained intact, or else re-suspended in distilled water and violently pounded so that most of them disintegrated. In neither case was carbonic anhydrase activity observed in the re-suspension, and the activity of the supernatant liquid after the first spin was the same as that of the uncentrifuged extract.

Finally, it is interesting to note that the list of plants at present known to contain carbonic anhydrase activity includes several—grapefruit, peach, tomato—which are subject to diseases such as mottle-leaf and little-leaf, now attributed to zinc deficiency. If, like animal carbonic anhydrase[4], the plant enzyme is shown to contain zinc, it will be interesting to examine the anhydrase content of zinc-deficient plants.

I am much indebted to Dr. T. Mann for a highly purified solution of animal carbonic anhydrase, and to him, Prof. F. J. W. Roughton, Dr. R. Hill and Mr. F. R. Whatley for advice and assistance.

Elaboration of Hydrochloric Acid by Gastric Mucosa

THE experiments the results of which are indicated below were designed to throw light on the mechanism of hydrochloric acid production in the stomach. In order to evaluate a theory of gastric acid elaboration, it is necessary to know the relative magnitude of the Q_{O_2}, Q_{CO_2} and Q_{HCl} of the mucosa and of the oxyntic cells. The maximum $|Q_{O_2}|$ observed in 144 isolated frog gastric mucosæ was 4 µl./mgm. dry wt./hr.[1]; the maximum Q_{HCl} observed in 139 mucosæ was 8 µl./mgm. dry wt./hr.[2]. (Conway and Brady[3] have misquoted our results[4], stating "when Q_{HCl} exceeded twice Q_{O_2}, with the mucosal sack immersed in bicarbonate saline, the tissue appeared damaged". In fact it was stated that the tissue was undamaged, and no claim was made that the Q_{HCl} exceeded twice $|Q_{O_2}|$[4]. Also on p. 137, three lines from bottom, "their Department" should read "our Department".)

The oxyntic cells are the only gastric cells which secrete hydrochloric acid, and they represent about one tenth of the total volume of the mucosa[1]. Thus as all the cells respire, the Q_{HCl} for maximally secreting oxyntic cells must be much greater than $|Q_{O_2}|$. This is confirmed by calculations[1] utilizing the results of Gray, Adkison and Zelle[5] (on frogs), Teorell[6] (on cats), Ni and Lim[7] and Hanke[8] (on dogs). The figures for human gastric mucosa give Q_{HCl} values between 50 and 100. Rosenthal and Lasnitzki[9] found that the Q_{O_2} of eleven samples of isolated human gastric mucosa lay between -5 and -20. It is thus clear that in the frog, cat, dog and man, the Q_{HCl} of oxyntic cells can be very much higher than $|Q_{O_2}|$.

When hydrochloric acid is secreted by oxyntic cells into the gastric tubules, an exactly equivalent amount of alkali is also produced. In the presence of carbon dioxide, virtually all this alkali is converted into bicarbonate ions and is secreted into the nutrient or organism side of the gastric mucosa[10,8,11]. Maximally secreting oxyntic cells with any possible respiratory quotient cannot provide sufficient carbon dioxide from their own metabolism to neutralize this alkali formed concomitantly with the acid. Therefore, the actively secreting stomach must utilize carbon dioxide extracted from the blood or surrounding tissues. At high rates of secretion, the rate of uncatalysed carbon dioxide uptake is quite insufficient to neutralize the alkali[1]. There is, however, enough carbonic anhydrase in cat oxyntic cells to magnify this rate of carbon dioxide uptake about 70,000 times[12,1], and it is probable that the failures of Feldberg, Keilin and Mann[13] and of Davenport[14] to inhibit acid secretion using carbonic anhydrase inhibitors were due to residual uninhibited enzyme. A magnification only of the order of a hundredfold is required, and this can be produced even if about 99·9 per cent of the enzyme is inhibited.

The suggestion of Conway and co-workers[15,3] that carbonic anhydrase accelerates the production of carbon dioxide, which the cell then excretes, seems most unlikely in view of Gray's comments[16] on the occurrence of a reversed chloride shift in blood passing through a secreting stomach.

Our evidence is contrary to the theories of Bull and Gray[17] and of Conway and co-workers[15,3], who postulated that the hydrogen ions come from acids such as pyruvic, succinic or carbonic formed from glucose during respiration. In the first two cases, the Q_{HCl} cannot be greater than one third $|Q_{O_2}|$[4]; in the last the Q_{HCl} cannot be greater than $|Q_{O_2}|$. Such mechanisms cannot produce more than six hydrogen ions when six molecules of oxygen react with one molecule of glucose; so Conway's statement that the hydrogen ions from an organic acid may supplement those from carbonic acid, or that a cyclical process[3] could give a Q_{HCl} far higher than Q_{O_2}, is not justified. Moreover, the aerobic glycolysis of gastric mucosa is slow compared with the respiration[9,1]. These facts rule out theories dependent upon the production of hydrogen ions by the fermentation or oxidative degradation of any carbon compound.

TWO RECENTLY SUGGESTED MECHANISMS PRODUCING HYDROGEN IONS FROM GLUCOSE OXIDATION

The insufficiency of chemical mechanisms of this type led us to investigate the possibility of a physico-chemical mechanism[18]. Since 1859 [19], there has been sporadic speculation as to the existence of a causal relation between the electric potential difference which exists across the gastric mucosa and the secretion of hydrochloric acid[20,21]. We have obtained the following results using isolated frog gastric mucosa[18,2]; they are comparable with those obtained by Rehm using live dogs[21].

(1) The secretory side of the mucosa was negative (in an external circuit) with respect to the nutrient side in all of 133 mucosa. The potential difference across reactive mucosæ was 20–50 mV.

(2) When acid secretion commenced, either spontaneously or induced by histamine, the magnitude of the potential difference decreased sharply by

10–20 mV., this decrease being greater for high secretion-rates than for low ones. At the end of secretion, whether spontaneous or due to the addition of sodium thiocyanate, the potential difference rose again.

(3) On no occasion during a total of 127 experiments was acid secretion or a potential difference observed in the absence of respiration produced by anoxia or respiratory inhibitors.

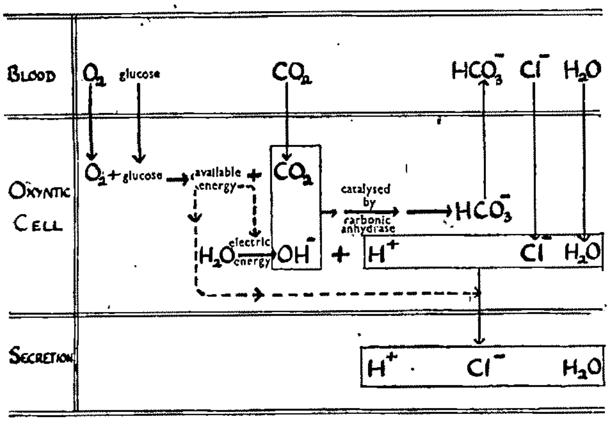
(4) When the two sides of the mucosa were connected electrically through a low resistance, a steady current was maintained, representing an expenditure of power by the mucosa of nearly 1 μ watt/mgm. dry wt.

(5) When an electric current of the order of 1 ma./cm.^{2} from an external source was passed through an acid-secreting mucosa in such a direction as to enhance its natural potential difference, the Q_{HCl} was increased by an amount up to 1·2 ± 0·1 μl./mgm. dry wt./hr. The same current opposing the natural potential difference inhibited the rate of acid secretion by an amount up to 2·8 ± 0·1 μl./mgm. dry wt./hr. When the same or even a much greater current was passed in either direction through œsophageal, pyloric, duodenal or rectal mucosa, frog skin, 'Cellophane', or dead gastric mucosa, no trace of acid was detected. Up to 5 ma./cm.^{2} passed through live gastric mucosæ, in which no acid secretion could be induced even by histamine, produced no detectable amount of acid; that is, the Q_{HCl} was less than 10^{-4}.

On the basis of these results, we suggest that the reaction fundamentally concerned in the production of hydrochloric acid in gastric mucosa is that which occurs when the cell

$$\text{hydrogen} \;\Big|\; OH^- \text{ aq.} \,\vdots\, H^+ \text{ aq.} \;\Big|\; \text{hydrogen}$$

is reversed by an external source of power. The reaction for one faraday is $H_2O = OH^- + H^+$.



SUGGESTED OVERALL REACTION ELABORATING HYDROCHLORIC ACID IN GASTRIC MUCOSA

The accompanying scheme suggests how the hydrogen ions are normally elaborated by means of energy available from glucose metabolism, and the hydroxyl ions finally neutralized by carbon dioxide from internal and external sources, and passed into the blood.

The experimental results that acid secretion is accompanied by a change in the potential difference across the mucosa, and that the rate of secretion is affected when this potential difference is changed by supplying electric power to the mucosa, suggest that electric power plays an important part in the mechanism of hydrochloric acid elaboration by gastric mucosa.

A full account of our experiments will be submitted to the *Biochemical Journal*.

Serum Chlorides in Pregnant Mice

DURING previous work on the serum chlorides of agouti and non-agouti mice, it was noted that pregnant mice usually gave lower results than non-pregnant. This has been investigated, using the technique previously described[1]. Estimations were made at the tenth day of pregnancy, as judged by the date of the vaginal plug and checked by the age of the embryos[2]. It is considered that the limits of departure from this date did not exceed 24 hr. All females were placed with the male at the age of eight weeks. They did not all become pregnant on the same day, due to variations in their œstrus cycles, so that there were differences in the ages at which the estimations were made, the greatest being four days. No relationship between these differences in age, either in pregnant or non-pregnant mice, and the chloride levels has been found. Controls were non-pregnant mice from the same litters at the same ages.

The accompanying table shows the results obtained expressed as milli-equivalents of chloride per litre of serum. The figures in brackets after the values for the pregnant mice indicate the number of embryos present.

Pregnant	Non-pregnant	Pregnant	Non-pregnant
128 (7)	130	120 (7)	121
122 (8)	133	120 (7)	126
122 (10)	127	120 (7)	133
116 (6)	131	117 (9)	122
115 (10)	123	120 (11)	122
117 (6)	128	117 (11)	129
117 (9)	124	120 (10)	122
114 (7)	134	118 (8)	131

The means for the two series were pregnant 119, non-pregnant 127. Estimation of the significance of the difference between these means was made[3] giving $t = 6\cdot114$ for $n = 30$. The limit of the published tables[4] is $P = 0\cdot001$, $t = 3\cdot646$ for $n = 30$. The difference is therefore highly significant, P being less than $0\cdot001$, and the definite statement may be made that there is a decrease in the serum chloride concentration in mice during pregnancy. There is no correlation between the serum chloride level and litter size.

The explanation of this decrease is at present obscure. There are many facts and theories which may be relevant, the following being considered to be the most obvious: the increase in salt appetite during pregnancy[5]; the relation of the ovaries to salt metabolism[6]; the effect of pregnancy on adrenalectomized animals[7]: the beneficial effect of restriction of salt intake on the toxæmia of pregnancy is well known; the theory that the fœtal adrenal cortices are active[8]; the hyperpigmentation of normal pregnancy; the influence of sodium chloride on melanin formation[9]. A working hypothesis has been formed from these and other statements; but there is in sufficient critical evidence to justify its publication at this stage. An attempt is being made to obtain the necessary evidence.

The work has been carried out with the aid of a grant for the Leverhulme Research Fellowship.

Microdetermination of Copper in Biological Substances

In the course of a series of investigations by F. Buscarons and E. Loriente[1,2] on analytical applications of 3,3′, 4,4′-diamine-3,3′-dimethoxy-biphenilo (*o*-dianisidin), these authors have shown that this substance in certain conditions possesses extreme sensitivity for cupric copper. We have used this reactant for colorimetric determinations of copper in the blood and in other biological substances.

The mechanism of the reaction is based in the green coloration that occurs when solutions containing cupric copper are treated with an acetic solution of orthodianisidin and afterwards with a slight excess of sulphocyanide. This coloration tends to change to yellow when the concentrations of copper are around $1/10^6$; if the concentration is greater than $1/5.10^5$ much blue precipitate is produced.

For the determination of the copper in small quantities it is necessary to purify all the reactants and use twice-distilled water in a glass apparatus; glass or porcelain burners should be used, because brass ones easily pollute the atmosphere. We use the wet method of analysis because by the dry method volatile copper products are easily formed. Nitro-perchloric acid is used, warming until the liquid is decolorized and there are plenty of fumes of perchloric acid. To eliminate the ferric iron which with the dianisidin gives a red coloration, we precipitate the copper as sulphide; and to help this precipitation, and to make the precipitate easier to handle, before passing the current of hydrogen sulphide through the solution we add a small quantity of 4 per cent lead acetate solution (dianisidin gives no colour with lead, at least in the conditions in which we work).

The precipitate is centrifuged and washed; it is then dissolved in some drops of nitric acid and evaporated to dryness on a bath at 150° in order to eliminate the nitric acid. The residue is dissolved with water, and to this aqueous solution we add a few drops of a freshly prepared and colourless acetic solution of dianisidin, and then ammonium sulphocyanide in a light excess, plus one third of the volume of the solution of ethyl alcohol. A green coloration is produced if copper is present; with quantities of copper less than a gamma per c.c. the colour turns yellow in 10–20 min. and remains at least two hours. This colour is compared colorimetrically with that produced by a standard solution of copper with a concentration similar to that suspected in the sample to be analysed and treated in the same way.

Vicinal Action in Steroids

The optical rotatory powers of steroidal compounds can be correlated by means of the method of molecular rotation differences, and such correlation has been shown to be of value in solving certain types of structural problem[1]. In some cases anomalies of optical rotatory power occur which cannot be ascribed to trivial causes, but which must be due to disturbing factors generally given the name 'vicinal action'.

It has been assumed that the forces responsible for vicinal action decrease with distance and must become inoperative beyond a certain point[3]; the magnitude of vicinal action may be represented by the expression $\Delta\,\Delta$ value as used in Tables 1 and 2. The fused-ring structure peculiar to steroids, together with other factors, makes these compounds particularly suited to the study of the variation of vicinal action with distance, and, accordingly selected examples have been examined from this point of view. Tables 1 and 2 refer to a number of compounds which have been prepared in a state of special purity and for which rotation measurements have been made in chloroform solution for the sodium D line. Specific rotations have been rounded off to the nearest degree in calculating the molecular rotations so that, in the absence of vicinal action, Δ_1, Δ_2 and Δ_3 values (see Tables 1 and 2) should agree with the corresponding standard values for cholesterol and cholestanol to at best ± 4.

* Δ^{4}-3-Ketones when from Δ^{5}-stenols.

The variation of vicinal action with distance can be assessed by the series of ketones where the carbonyl group is removed progressively further from the 3-position, and by the series of unsaturated sterols where the double bond is similarly removed progressively to a more remote position relative to the hydroxyl group. Inspection of Tables 1 and 2 reveals that in the series of carbonyl compounds vicinal action does indeed decrease with increase of distance. The same general effect is to be noted in the series of unsaturated sterols, although the decrease of vicinal action with distance is by no means regular. In general, the magnitude of the Δ Δ values depends on the particular transformation under consideration at the 3-position, being usually small for acetates and saturated ketones, but large for benzoates and Δ^{4}-3-ketones, and also upon the nature and position of the variable substituent placed elsewhere in the molecule.

Considering, for the moment, molecules retaining unaltered the configurations of cholesterol and cholestanol and their simple functional derivatives in rings *A* and *B*, which have substituents in rings *C* and *D* or in the side-chain, certain generalizations can be made regarding the incidence of vicinal action. Without doubt anomalies only occur in those cases where two easily polarized groups are present, and it is shown that vicinal action can in certain cases be transmitted from the side-chain to the 3-position, a distance of more than 10 A. There is, however, an additional requirement besides that of polarizability, which would seem to depend upon the capacity of the substituent groups for distorting the molecular framework.

Still considering steroid molecules substituted as mentioned above, it is possible to classify substituent groups into three classes, as indicated below, in the third of which are placed those groups which are specially to be expected to distort the framework of the molecule. Clearly, there is no rigid dividing line between the groups placed in classes 2 and 3, and to a considerable extent the incidence of vicinal action must depend upon the actual position of the groupings in the molecule. The ethylenic linkage must be placed in both classes 2 and 3, although molecules containing two ethylenic linkages, one in the side-chain and the other in the steroidal nucleus, do not exhibit large optical anomalies.

(1) No anomalies in molecular rotation, C—H, C—C, C—OH.

(2) Anomalies only in the presence of class 3 substituents, C—O.CO.CH_3, C—O.CO.C_6H_5, C=O, C=C.

(3) Causing anomalies if another member of classes 2 or 3 be present, C=C, C=C—C=O, C=C—C=C.

Gamma-Radiation from Polonium and from Lithium Bombarded with Alpha-Particles

IN connexion with the study of the secondary radiation emitted when a number of light elements were subjected in turn to the alpha-radiation emitted by a strong sample of polonium, Bothe and Becker[1] found that polonium also emitted a hard gamma-radiation. The intensity of this was low, about one gamma-quantum being emitted for 10^5 alpha-particles. The gamma-radiation of polonium was interpreted as resulting from the fact that one of 10^5 alpha-particles was emitted with a lower energy than the rest, leaving the nucleus in an excited state, from which it returned to the ground-state with emission of a gamma-quantum. This gamma-quantum is able in its turn to release an electron from the new nucleus (RaG = Pb^{206}) or the electron shell of nearby atoms, thus causing a secondary beta-radiation. Bothe[2] investigated this beta-radiation with the aid of a beta-spectrograph of high light intensity (semi-circular method).

The beta-spectrum obtained by Bothe shows three 'certain' and two 'uncertain' maxima. The five maxima were thought to be due to gamma-lines with the energies 202 (355), (433) 798, and 1,068 keV. (values corresponding to uncertain maxima are in brackets).

The interpretation referred to above of the gamma-radiation from polonium requires a fine structure in the alpha-particles. Rosenblum[12], and Rutherford and co-workers[14], sought for this in vain. By the use of a large, magnetic alpha-spectrograph, Chang[4] recently succeeded in finding quite a complicated fine structure, consisting of twelve different ranges apart from the maximum. The yet unconfirmed results of Chang have been discussed by Feather[5].

In another investigation, Bothe[3] studied the secondary beta-spectra due to the gamma-radiation from some lighter nuclei which were excited by alpha-particles from polonium. Here the polonium, as the only gamma-radiating substance, was enclosed in a lead capsule with walls 0·6–1 mm. thick. In this manner a Compton- and photo-spectrum was obtained the structure of which was rather monotonous and did not offer any safe foundation for a determination of the energy of the gamma-radiation. The curve was used for ascertaining the background which had to be deduced in order to get the Compton- and photo-spectrum of the gamma-radiation from the processes they released, when lithium, fluorine and beryllium in turn were bombarded with alpha-particles from polonium. As regards the spectrum of lithium, Bothe considered that this consisted practically only of photo-electrons, and that the appearance of the spectrum permitted the determination of two certain bands and a faint one, which were denoted as "weit weniger sicher". The energies of the gamma-lines were estimated as 0·59, 0·39 and (0·2) MeV. respectively. According to Bothe, it is here a question of excitation of the more common Li^7-nucleus without capturing the alpha-particle.

If Bothe's interpretation of the gamma-radiation as being due to the excited Li^7-nucleus is correct, this should be capable of confirmation also by investigation of the proton or alpha-particle ranges from the reactions $\mathrm{Li}^6(dp)\mathrm{Li}^7$, $\mathrm{Li}^6(dp)\mathrm{Li}^{7*}$, $\mathrm{B}^{10}(n\alpha)\mathrm{Li}^7$ or $\mathrm{Be}^9(d\alpha)\mathrm{Li}^7$ [13,18,10,7,9,6].

The energy in the gamma-radiation from Li^{7*} can, ultimately, be obtained by the study of Be^7, which with a half-life of 53 days[8] by *K*-capture passes into the ground-state of Li^7, in such a way that 10 per cent of the disintegration leads to Li^{7*}, the remaining 90 per cent into the ground-state Li^7. When the former nucleus passes into its ground-state, there is emitted a gamma-quantum of just the energy which is of interest in our work. One of us[16] investigated the photo-effect released in lead-foil by means of a magnetic lens spectrograph, and obtained from the well-marked *K*- and *L*-photo lines for the energy of the gamma-radiation the same value, 453 keV.

Only Bothe has found several components in the gamma-radiation from Li^{7*} as well as from polonium. It therefore seemed to us[17] desirable to test these results by making use of the reliable method of investigating the photo- and Compton-effect in lead in the magnetic lens spectrograph[15].

In a small cylindrical platinum dish with an outside diameter of 8 mm., a height of 2 mm. and a depth of 1 mm. (thickness of metal 1 mm.), there was evaporated drop after drop of a solution of polonium chloride (86 mC.). The platinum dish was then introduced into a cylindrical lead radiator, after which the radiator was closed with a lead cylinder, which was soldered fast in the radiator with the aid of Wood's metal. The gamma-radiation from platinum released in the 0·5 mm. thick bottom of the radiator photo- and Compton-electrons, the energy of which was determined by use of the spectrograph. For excitation of lithium nuclei a similar radiator was used as for the polonium, the only difference being that a layer of metallic lithium of 0·5 mm. thickness was applied to the bottom of the radiator.

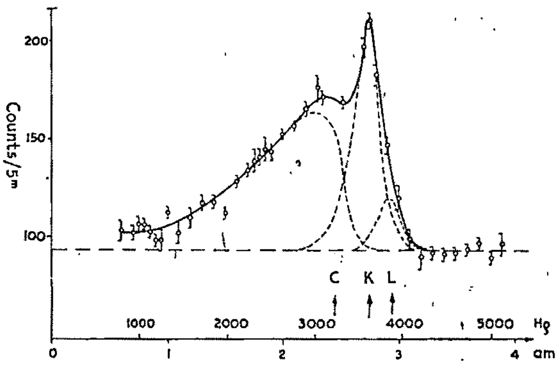

Fig. 1. PHOTO- AND COMPTON-ELECTRON SPECTRUM OF THE GAMMA-RADIATION FROM POLONIUM IN A LEAD RADIATOR

Fig. 1 shows the photo- and Compton-spectrum obtained from polonium in the lead radiator. The curve was prepared as a mean value of sixteen series of measurements. It is possible to notice a well-marked photo-line *K* with a half-value width, which corresponds to the resolving power of the apparatus. From the $H\rho$-value 3610 there is obtained for the beta-energy the value 0·685 MeV. When the ionization work of the *K*-electrons in lead (0·088 MeV.) is added to this value, we get the energy 0·773 MeV. of the corresponding gamma-line.

In Fig. 1 arrows at *C* and *L* mark also the positions of the Compton-edge and the *L*-photo line, which give the same energy of 0·773 MeV. for the gamma-radiation studied, while dotted curves give the three components, corresponding to the Compton-, *K*-photo- and *L*-photo-electrons, into which the experimental curve can be resolved.

The curve shows that the gamma-radiation from polonium is mono-energetic, in contradistinction to the result obtained by Bothe. Bothe's value for the energy in the strongest photo-line, 0·798, agrees well with ours.

If a gamma-radiation of any other energy than 0·773 MeV. is emitted from polonium, it is at any rate extremely weak in comparison with the 0·773 radiation. It must therefore be noted as a remarkable circumstance that, in the fine structure found by Chang in the alpha-particles among the twelve satellite groups, there is not noted any group that is distinguished by specially high intensity or

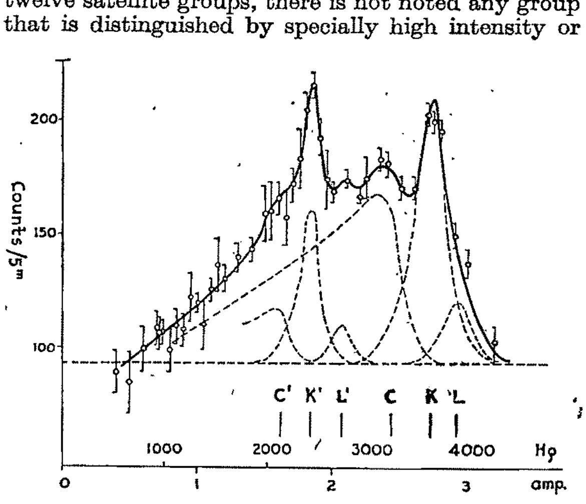

Fig. 2. PHOTO- AND COMPTON-ELECTRON SPECTRUM OF THE GAMMA-RADIATION FROM LITHIUM (IN A LEAD-RADIATOR), WHICH WAS BOMBARDED WITH ALPHA-PARTICLES FROM POLONIUM, AS WELL AS THE GAMMA-RADIATION FROM POLONIUM

by the difference in energy as compared with the main group at 0·773 MeV.

The photo- and Compton-spectrum of the lithium sample was investigated in the same manner as above. Fig. 2 shows the result. We recognize the C, K and L structure just described in the spectrum of polonium. On this has been superimposed the photo- and Compton-electrons denoted respectively by K', L' and C', released by the gamma-radiation from lithium. From the K-line we get $H\rho = 2430$, or an electron energy of 0·374, from which for the lithium gamma-radiation we get the value 0·462 MeV. The L'-line gives 0·471 MeV., and the Compton edge position C' has been drawn in such a way that the corresponding gamma-energy is equal to that which is obtained from the K'-line, which, of course, gives the most reliable result. In Fig. 2 the dotted curves indicate those components into which the experimentally obtained curve (mean of nine series) can be resolved.

The result shows that the lithium nucleus sends out only one kind of gamma-quantum, and that their energy is 0·462 MeV. That Bothe believed he had found a line at 0·39 MeV. was clearly due to his interpretation of the Compton electrons due to 0·462 MeV. radiation as photo-electrons released by some other gamma-radiation. This condition of affairs shows that the Compton-electrons in the gamma-energy dealt with are not negligible.

The value of the gamma-radiation energy, 0·462 MeV., is within the limits of error identical with the value 0·453 MeV., which one of us[16] has found for the radiation from Be^7, and thus constitutes a confirmation of the last-mentioned measurement, and also of the conception regarding the origin of the gamma-radiation, namely, the transition of the excited Li^{7*}-nucleus to the ground-state Li^7. There is thus confirmed here likewise the hypothesis of excitation of the Li^7-nucleus by inelastic collisions with the alpha-particles from polonium and of the K-capture by Be^7.

The value 0·462 MeV. also agrees very well with the values for the energy of the gamma-radiation from Li^7, which was obtained by Rumbaugh *et al.* as well as Hudson *et al.*

Interaction of Fast Neutrons with Beryllium and Aluminium

THE total cross-sections for the scattering of fast neutrons of known energy by a number of light elements have recently been published[1,2]. The results for the elements carbon and oxygen show resonances at certain values of the neutron energy, and these resonances are ascribed to energy-levels in the compound nucleus formed in the scattering process. Similar resonances in (n,α) transmutations produced by fast neutrons have been known for some time[3,4], but no case has yet been reported in which both the total neutron cross-section and the (n,α) transmutation cross-section for a given element have been shown to involve the same level of the compound nucleus. We have been able to demonstrate this in the case of beryllium, which when bombarded by fast neutrons can yield $^6\mathrm{He}$ in accordance with the reaction[5]

$$ {}^{9}\mathrm{Be} + {}^{1}n \rightarrow {}^{10}\mathrm{Be} \rightarrow {}^{6}\mathrm{He} + {}^{4}\mathrm{He} - 0\cdot8\,\mathrm{MeV}. \quad (1) $$

The total neutron cross-section for beryllium was measured by the transmission method used by other workers[1,2,6]; D + D and C + D neutron sources were used. The observed total cross-section, corrected for inhomogeneity of the incident neutrons, is plotted against neutron energy in Fig. 1 and shows a resonance at 2·6 MeV. The results of other workers[7,8,9] are also plotted in this figure, and taken together with the present results may indicate a further resonance at 0·55 MeV. The (n,α) transmutation cross-section was measured over the same range of neutron energies above its threshold as the total cross-section by observing the 0·86 sec. $^6\mathrm{He}$ β-activity induced by the neutrons in a beryllium-walled Geiger counter. The results of these measurements are

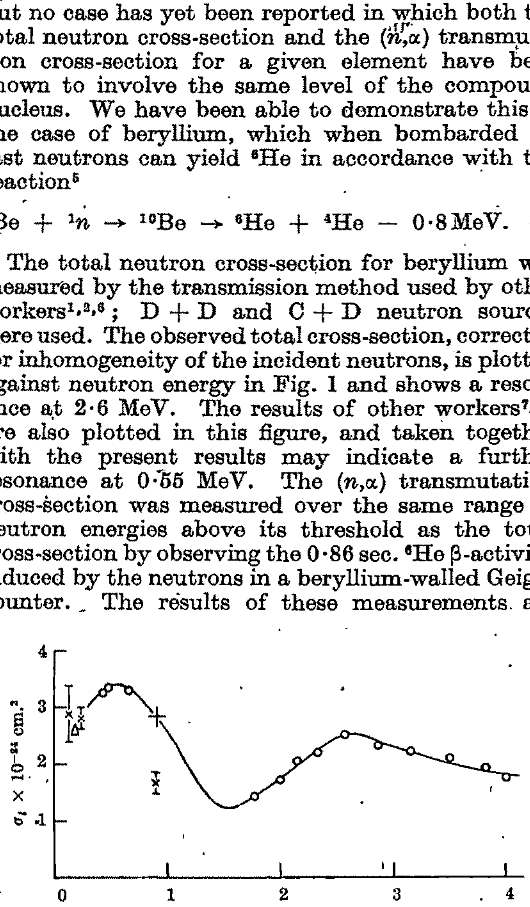

Fig. 1. TOTAL NEUTRON CROSS-SECTION (σ_t) OF BERYLLIUM. CIRCLES ARE THE PRESENT RESULTS; OTHER POINTS ARE DUE TO PREVIOUS WORKERS (REFS. 7, 8, 9)

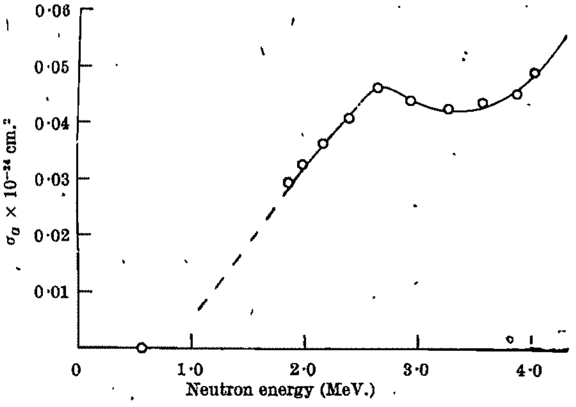

Fig. 2. CROSS-SECTION (σ_a) FOR THE REACTION $^9\mathrm{Be}$ (n,α) $^6\mathrm{He}$

shown in Fig. 2, from which it is clear that a resonance in the (n,α) reaction also occurs at 2·6 MeV.

If it is assumed that the interaction of a 2·6 MeV. neutron with the beryllium nucleus can be considered as analogous to a slow neutron process, the procedure given by Bethe[10] can be applied to show that the width of the level in the ^{10}Be nucleus responsible for the resonant scattering is between 0·8 and 1·0 MeV. This corresponds to a life-time of the ^{10}Be nucleus in this excited state of about 10^{-21} sec., which is longer than the time necessary for a 2·6 MeV. neutron to cross a ^{9}Be nucleus and is, therefore, some evidence for the formation of a compound state in the scattering process. The ratio of the (n,α) transmutation cross-section to the total cross-section at 2·6 MeV. is about 1/50; this is of the same order as the penetrability of the potential barrier of a light nucleus like ^{6}He for an α-particle of the energy available according to (1).

Some of the measurements on beryllium were made with a beryllium–aluminium alloy of known composition, and correction for the presence of the aluminium made determinations of the total cross-section of this element necessary. Two resonance levels were found in the energy range 1·8–4·0 MeV.; one, at 2·4 MeV., has already been found by other workers[6,11]; the other, at 2·9 MeV., is new. Both levels have a width of about 0·2 MeV.

Further details of this work, which was carried out during the period November 1945–June 1946, will be published later.

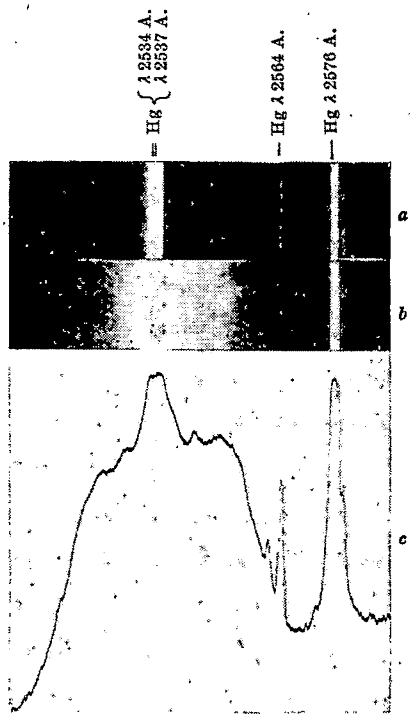
Born's Theory and the Spectrum of Light Scattering of Crystals

ACCORDING to Born's theory $3N$-6 vibrations of the crystal lattice must take place in a crystal (N is the number of atoms of the crystal). Consequently the spectrum of elastic vibrations of a crystal must be quasi-continuous. According to Born, this relates to the acoustic as well as to the optical branch of the spectrum of elastic vibrations of a crystal. The most complete analysis of the spectrum of elastic vibrations of a crystal, based on Born's theory, was carried out for rock-salt by Kellermann[1].

For some time past the basic conception of Born's theory has been criticized by Raman[2] and his collaborators. According to Raman, the optical branch of the spectrum of elastic vibrations of a crystal is not continuous but consists of a small number of discrete lattice vibrations of the crystal. The experimental investigations of the spectrum of second-order scattering of crystals are of great interest because they alone afford the possibility of obtaining the most complete picture of the whole spectrum of elastic vibrations, and thus of deciding which of the two theoretical conceptions referred to above is correct.



a, MERCURY SPECTRUM; *b*, SPECTRUM OF SECOND-ORDER SCATTERING BY A CRYSTAL OF POTASSIUM CHLORIDE; *c*, MICROPHOTOMETRIC RECORD OF *b*. *b* AND *c* SHOW A STRONG CONTINUOUS BACKGROUND

The most appropriate objects for such investigations are the crystals of alkali halides. Their simple structure simplifies the theoretical calculations of the spectrum of elastic vibrations and stipulates a simpler spectrum of scattering. The spectrum of second-order scattering for rock-salt, which consists of a group of broad maxima superimposed on a continuous background, was for the first time obtained by Fermi and Rasetti[3] and can be completely explained from Born's point of view[4].

Recently, Krishnan[5] investigated the scattering of rock-salt and some other crystals. He considers the results obtained to be in contradiction with Born's theory and in agreement with Raman's conception. In his experiments Krishnan did not observe the continuous background in the spectrum of second-order scattering of crystals, and its absence he regards as a most essential experimental fact which contradicts Born's theory. According to Krishnan, the spectrum of crystals consists of a number of discrete lines only, and Krishnan considers this to confirm Raman's conceptions.

The continuous background of the spectrum of the second-order scattering is a fundamental deduction from the theory of Born; therefore, the question of its existence or non-existence is of primary importance. For that reason we undertook new investigations of alkali halide crystals (potassium chloride, potassium bromide, and once more of rock-salt), our principal aim being to ascertain the existence of a continuous background in the second order Raman spectrum.

As other workers have done, we used as the exciting radiation the mercury resonance line λ = 2537 A. The crystals investigated were prepared from the corresponding fused salts. Our arrangement enabled us to obtain spectra of the second order in 5 hours with a slit-width of the spectrograph of 0·015 mm.

Our results show that the spectra of second-order scattering by crystals of potassium chloride, potassium bromide and sodium chloride are of the same type. The spectra are continuous, and on the background some discrete broad maxima of intensity are observed. The frequencies of the most distinct maxima for potassium chloride are 121 cm.$^{-1}$ and 201 cm.$^{-1}$, for potassium bromide 85 cm.$^{-1}$, 137 cm.$^{-1}$ and 204 cm.$^{-1}$. The distribution of intensities and the length of the spectra are different.

In the accompanying reproduction, the spectrum of a crystal of potassium chloride and its microphotogram are shown: an analogous microphotometrical curve was obtained for potassium bromide. The continuous spectrum of scattering of a crystal of potassium chloride is seen very distinctly.

We consider that the results of our investigations confirm Born's theory of the crystal lattice and contradict the conceptions of Raman.

Oil-drop Method for Electron Trajectories

DEVELOPMENTS in electron optics during the past ten years have included automatic methods for plotting the electron trajectories through the fields of electrostatic electron lenses. These are exemplified by the ingenious devices of Gabor[1] and Langmuir[2], which also enabled the effect of selected portions of the field to be separately investigated. However, the apparatus required for such determinations is highly specialized, and not within the reach of the average laboratory. The alternative method of obtaining the potential distribution from electrolytic tank measurements, and enlisting the aid of the differential analyser to solve the trajectory equation, where this is possible, is again confined to institutions with the necessary equipment, and this may not be readily available.

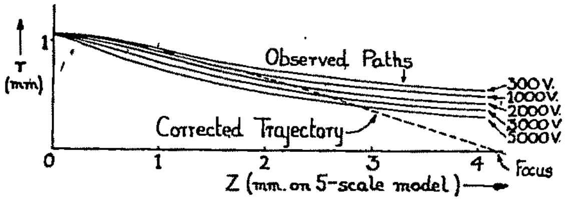
A method tried here seeks to overcome these inconveniences, by observing the trajectory of a charged oil drop in the actual field of the lens, in air at atmospheric pressure, and this is corrected by a simple calculation. (In high vacuum the trajectory of the oil drop would be that of an electron, since the path followed is independent of the e/m ratio of the particle.)

Use was made of the Millikan oil-drop technique or producing charged particles. The following liquids were tried: turpentine, water, colloidal gold, glycerine, nut oil, 'Apiezon' oil, colza oil. It was finally decided to use colza oil for the work in air (and 'Apiezon' oil for the later experiments in vacuum). The drops are blown into a chamber from a commercial atomizer using compressed air. They then fall under gravity into a glass cylinder which contains an enlarged model (× 5) of the electron lens, and thus into the field of the lens through three collinear small holes in the cathode, one central, the others 1 mm. on either side of it. A field established by giving suitable potentials to the electrodes acts upon the charged droplets, causing them to describe curved paths, in the field of the lens. The paths are made visible by scattering the light from a 1,000-watt projector lamp, which is concentrated by a series of lenses to give a beam of about 5 mm. diameter at the centre of the chamber. The actual trace can be followed and timed as the droplets cross the 'square' eyepiece of a low-power microscope, and a space-time curve plotted for both the axial and radial directions. The data obtained in this way in air are sufficient to enable a first approximation to the trajectory to be determined, and to give the form of the potential distribution along the axis, assuming that paraxial regions of the field are explored. Owing to the presence of the air, a term which allows for the viscosity effect has to be introduced into the equations of motion; these now take the form:

$$m\frac{d^2z}{dt^2} = q\frac{\partial V}{\partial z} + mg - 6\pi\mu a v_z,$$

$$m\frac{d^2r}{dt^2} = q\frac{\partial V}{\partial r} - 6\pi\mu a v_r,$$

where q is the charge, and a the radius of the drop. Both accelerations are small in air; the gradients can then be expressed in terms of the velocities.



The charge and weight of the droplet are determined as in Millikan's experiment from observations on the free fall under gravity, and under a uniform field. The time to traverse the field was roughly of the same order as in his experiments, and the use of Stokes' law appears justified under these conditions. Since the longitudinal and radial velocities, v_z and v_r respectively, could be observed, the field distribution is obtained by one graphical integration, and the radial displacement by two such integrations. The accompanying curves show the average of a large number of observed trajectories for an average value of mass and charge of 4×10^{-13} gm. and $(9\,e)$ respectively, at various anode voltages, together with the corrected trajectory for an anode voltage of 1,000 V. This gives values of focal length (or cross-over distance) of the immersion objective some 30 per cent higher than the theoretical, but capable of much improvement with more accurate measurements.

A first-order approximation can thus be obtained directly by this simple means. While most of the electron optical systems in use have rotational symmetry, this is not a strict requirement of the method, since the path is integrated automatically in the presence of the field, no matter what form this takes.

It is interesting to record the effects seen in the eyepiece as soon as the charged droplets enter the viewing space. These are four in number: (1) straight-line paths indicating the presence of neutral drops; (2) curved tracks due to the focusing field, and directed into the centre of the field; these correspond with the paths of negative particles; (3) curved tracks, away from the centre of the field, corresponding with positively charged particles; (4) straight-line tracks, in the early part of the field; these may begin to curve inward or outward owing to pick up by neutrals of a negative or positive charge.

As the sizes of drops ranged from less than 0·5 μ to 5 μ, that is, of the same order of magnitude as bacteria, the method opens up possibilities of 'focusing' charged bacteria and viruses by the use of electrostatic focusing lenses. The form of the field lines shows that in this case a maximum concentration of the charged bodies would be found at the 'cross-over' of the system. This is comparatively easy to locate. The use of plane fields, while not producing any focusing, would result in a sweeping out or filtering action, which might be beneficial from the public health point of view if suitably designed and placed in public places.

It is hoped to publish these results shortly and continue the work in vacuum at a later date.

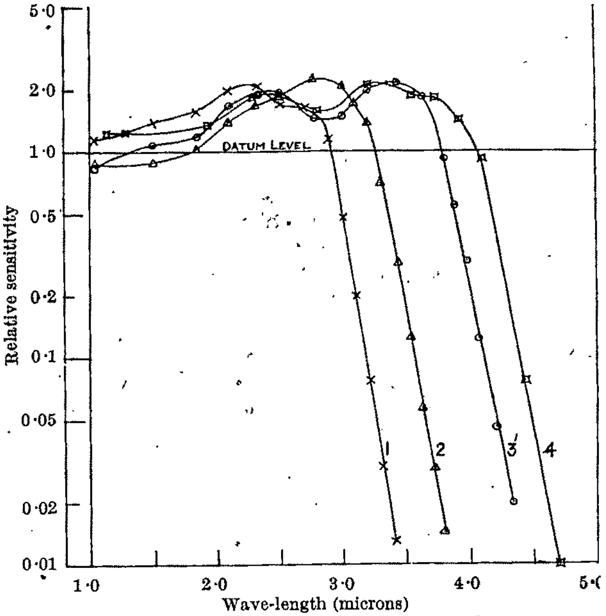
Spectral Sensitivity of Lead Sulphide Layers

Lead sulphide photo-conductive layers are now known as sensitive detectors in the near infra-red[1], but so far their usefulness has been limited to wave-lengths less than about 3 μ.

Measurements have been made on the spectral sensitivity of such photoconductive layers, and it has been found that there is a pronounced shift of sensitivity towards longer wave-lengths on cooling. The measurements were made with a Nernst source and a lithium fluoride (double prism) spectrometer in the region 1–5 μ, the spectral band-width varying from 0·08 to 0·03 μ over this range. The radiation from the Nernst filament was interrupted at 800 c./s. before entering the spectrometer, the signal from the layer being amplified in a receiver tuned to 800 c./s. with a band-width of 16 c./s.

The particular layer for which the results are quoted was made by chemical deposition, and had an area of 1 cm. × 1 cm., with a thickness of the order of 1 μ. As the accompanying figure shows, the wave-length at which the sensitivity has dropped to half its maximum value increases from 2·9 μ to 4·1 μ on cooling from room temperature to liquid hydrogen temperature. The curves are plotted as ratios of signal to root-mean-square noise in the absence of signal, and are relative to a datum level the value of which is quoted for each temperature. The glass of which the container for this layer was made has good transmission in the infra-red, with 90 per cent transmission up to 4·0 μ (except for a broad dip to 70 per cent at 3·0 μ) falling to 50 per cent at 4·5 μ. Practically all lead sulphide layers previously available were in 'Pyrex' glass containers the transmission of which is very poor beyond 3·5 μ, making it difficult to measure the true spectral response of the layer.



Signal/noise ratios for 16 c./s. band-width
Curve 1 : 290° K. datum S/N = 2·1 for 1 μ watt
" 2 : 195° K. " " 160 " "
" 3 : 90° K. " " 580 " "
" 4 : 20° K. " " 570 " "

The optimum sensitivity, achieved when cooling with liquid oxygen or hydrogen, is such that signal is equal to noise for an incident energy of 8×10^{-10} watts. This is approximately equal to the performance of the best available thermocouples, for the same equivalent noise band-width. However, the speed of response of the lead sulphide layer is some hundred times faster than that of a sensitive thermocouple; which is an important factor for many applications of such infra-red detectors.

The time constant of the lead sulphide layer was measured by irradiating it with a square pulse of light and measuring the rate of decay of the resultant signal on a cathode ray tube. The time measured is that required for the signal to decay to 1/*e* (37 per cent) of its initial value. The time of rise is only about two thirds of the decay time, and could not conveniently be measured in all cases.

Temperature	Decay time constant
290° K.	14 micro-sec.
195° K.	210 " "
90° K.	490 " "
20° K.	340 " "

The spectral shift is particularly important if the layer is to be used as a detector of radiation from a distant source, since in the near infra-red region the atmosphere is relatively non-absorbing only in the bands 2·0–2·3 μ and 3·3–4·0 μ.

For sources of moderate temperature (100°–300° C.) far more energy is radiated in the longer wave-length 'window', and thus cooling the layer greatly increases the signal received.

The above work was carried out at the Telecommunications Research Establishment (Ministry of Supply), and thanks are due to Dr. G. B. B. M. Sutherland for assistance in the liquid hydrogen measurements, and to the Admiralty Research Laboratory for supplying experimental layers.

Electrical Conductivity of Molybdenite Crystals

Recently, the magnetic properties of molybdenite crystals have been studied in this laboratory at room temperature[1] and also at both high and low temperatures[2]. It was then thought desirable to extend the investigations on this crystal to electrical conductivity. The electrical conductivity of single crystals of molybdenite has been measured by various workers[3], but a more systematic study of the electrical properties was necessary in order to understand the nature of the carriers of the electric current in this crystal.

The electrical conductivities of some well-developed single crystals of molybdenite were measured at room temperatures and also at high and low temperatures (from 100° K. to about 500° K.). Conductivity along the basal plane ($\sigma_{\perp}$) is about 10^3 times greater than that at right angles to the basal plane ($\sigma_{\parallel}$). At room temperatures for currents both along and at right angles to the basal plane Ohm's law is not obeyed. But if the temperature of the crystal is raised to about 420° K., Ohm's law is perfectly obeyed for currents along both the directions (Fig. 1).

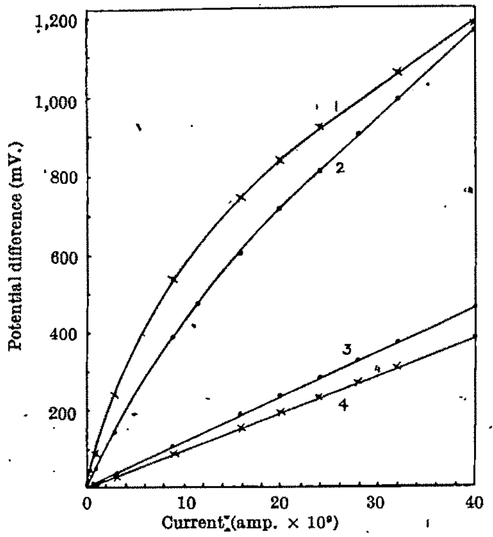

Fig. 1. Curve 1. Current-voltage curve for current at right angles to the basal plane at room temperature. Curve 2. Current-voltage curve for current along the basal plane at room temperature. Curve 3. Same at 420° K. Curve 4. Current-voltage curve for current at right angles to the basal plane at 420° K.

From the nature of variation of the conductivity with temperature, it has been found that at low temperatures the conductivities along both the directions have a tendency towards a temperature-independent value (Fig. 2). It is further apparent from the temperature variation of the conductivities that for both directions of the crystal there are two types of conductivities, one predominating at lower temperatures and the other at higher temperatures (Fig. 2).

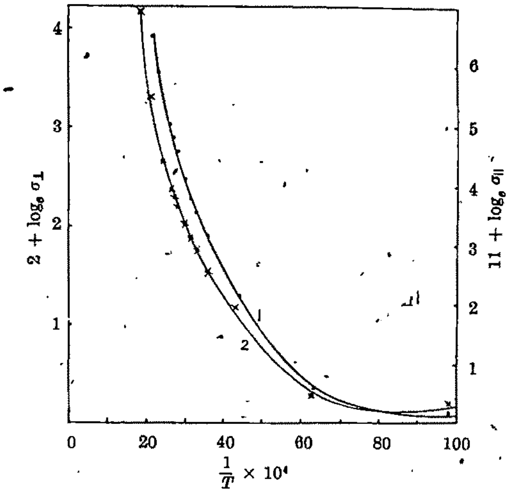

Fig. 2. Curve 1. Curve for current along the basal plane. Curve 2. Same for current at right angles to the basal plane

From these results it seems that the conductivity in molybdenite crystals at higher temperatures is effectively electronic.

Details of these investigations will shortly be published elsewhere.

Disappearance of *Zostera marina*

This very common flowering plant used to cover large areas of estuaries of Britain, but about fifteen years ago it died out almost completely on both sides of the Atlantic, though not on the Pacific coasts of the United States. Evidence as to the present condition is now being sought, both here and in America. It would be much appreciated if those who knew the *Zostera* beds formerly would please send information as to continued absence or extent of regeneration, also as to whether anything else now occupies the areas thus left bare. The late Dr. E. J. Butler informed me in September 1938 that annually since 1932 he had watched a small 'meadow' in Guernsey. Though about 75–90 per cent went the first year, the rest was then holding its own. The fungus *Ophiobolus halimus*, Diehl and Mounce, was always present on it, but there was no sign of extermination. In fact, he thought there was some increase. There is very little of it around here now.

Colours of Jupiter

In an interesting speculation, Wildt[1] suggested that the red and blue colours observed on Jupiter may be due to combinations of the alkali or alkaline earth metals with the ammonia which forms a large part of its atmosphere: the red to concentrated or 'metallic' solutions, the blue to dilute solutions. He left open the question of the source of the metals, but favoured the idea of meteoric dust, because of the spectroscopic detection of sodium in the night sky.

Although ingenious, the theory is improbable on several grounds. Even in the complete absence of oxygen and water it does not appear that the considerable quantities of metal required could be accumulated over the necessarily long period of time (the 'metallic' phase is $7N$ with regard to sodium at $-110°$), since it is known that light[2], and traces of transition metals, especially iron[3], which occur in meteoric dust, catalyse reaction with ammonia to give the colourless metal amides. Also, the red colours have been described as varying from 'brick-red' to 'rose-pink', while the 'metallic' phase of sodium in ammonia has a lustre of polished bronze, and solid calcium hexammine resembles brass; both are blue by transmitted light in thin layers. It is most unlikely, therefore, that they can give rise to true red colours either in solid, liquid or dispersed states.

The blue colour of metals in ammonia (visible at concentrations of less than $0{\cdot}00002N$ even with small volumes) is due to solvated electrons[4] and may be observed in solutions of ammonium (NH_4+, $e-$), so that a process for generating electrons (or ammonium radicals) may give rise to such a colour. On Jupiter possible sources of these may be found in photochemical reactions or atmospheric electrical charges.

The Desert Landscape

With arable land one of the most outstanding problems of the day, it is important to determine the criteria of the desert landscape so that reconstruction through the soil can be planned and commenced on a world scale[1]. Various definitions have been given of the nature of a desert, mostly based on weather (although the writers really mean climate), such as lack of rainfall or high rate of evaporation.

All such definitions become unwieldy and unworkable when applied in practice. For example, there is no lack of deserts which have high rainfalls, up to 60 in. per annum. Others have 20 in. and are still barren. It is difficult to formulate desert criteria unless the problem is approached from the soil point of view. If we define the desert landscape as one where the rate of soil erosion exceeds the rate of soil formation, and a genial area as one where the rate of soil formation is commensurate with erosion, then at once we have a dynamic conception which the soil conservationist can apply with vigour to his problems. This definition has the advantage that deserts are more likely to occur in areas where the equilibrium between rainfall and rate of evaporation is unstable, and hence deserts may form easily by soil erosion, without requiring changes of climate. This applies to South Africa, and many workers have shown the desert invasion that is now taking place without any change in climate that can be detected. Dr. Tidmarsh in the Karroo has prepared maps showing the increased desiccation of the soil that has taken place in the span of a few generations. With my colleagues I have drawn maps showing the present invasion, and others of the Pleistocene, Pliocene and Miocene are now being completed[2].

It is interesting to compare Pole-Evans' vegetation map with the rainfall distribution map of South Africa. There is general agreement, it is true, but very serious discrepancies in the central regions where desert vegetation is shown in rainfall areas of 20 in. per annum or more. When Pole-Evans' map is compared with that compiled by my colleagues and I, there is seen to be very close agreement indeed. In our map, as now brought up to date, the similarity is very close. When it is borne in mind that the maps were based on different criteria (in our map, on the sheet erosion that occurs in an area), then it is realized that this experimental approach has real merit.

Action of Mustard Gas (ββ′-Dichlorethylsulphide) on Thiol Groups of Proteins

In order to avoid any mistaken interpretation of the facts published in various papers[1], we wish to state clearly that the ββ′-dichlorethylsulphide we used in our investigations was a very pure colourless liquid of constant melting point prepared from constant-boiling thiodiglycol by the action of hydrochloric acid. It is known that impure mustard gas reacts more readily with —SH groups than the pure substance[2]. It appeared from the discussion at the recent Congrès de Chimie Biologique (Liège, October 1946), following the presentation of a paper by Prof. R. A. Peters, that our conclusions about the action of the various war toxic gases are generally in close agreement with those of the British and American authors (see ref. 3).

A VOLUMETRIC METHOD FOR A STUDY OF THE HISTORY OF EPEIROGENIC MOVEMENTS

By ALEXANDER B. RONOV

Institute of Theoretical Geophysics of the Academy of Sciences of the U.S.S.R., Moscow

ANY territory which is sufficiently large may be divided for any geological age into areas of tectonic uplifts and subsidence of the earth's crust, the rate of uplift and subsidence being different for different places[1]. One may speak about an average and a 'volume' rate of subsidence and uplift, meaning the rate of increment of the total volume of all the tectonic depressions and convexities of the earth's crust within a given territory. This total volume rate of movements may be calculated. The volume of subsidences is approximately equal to the total volume of sediments accumulated during the given time. An elevation of the earth's crust causes erosion, and the volume of the uplift may be determined from the volume of the eroded clastic material[3,4]. In this way the problem is confined to a determination of the volumes, on one hand, of all the deposits accumulated; and on the other, to a separate determination of those of clastic deposits. Tracing from one geological age to another the change of these values, it is possible to study in volumes (cu.km.) the kinematics of the vertical movements of different signs. Referring these volumes to a unit of area (sq. km.) gives the average magnitude of subsidence or uplift of the earth's crust (in km.).

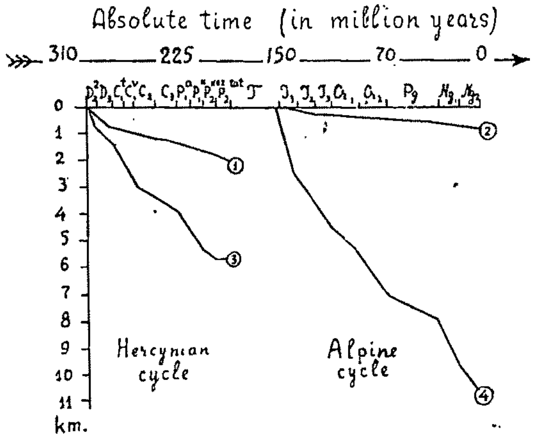

Fig. 1. CURVES SHOWING THE AVERAGE MAGNITUDE OF SUBSIDENCE OF THE HERCYNIAN (1) AND ALPINE (2) RUSSIAN PLATFORM, THE HERCYNIAN GEOSYNCLINE OF THE URALS (3), AND ALPINE GEOSYNCLINE OF THE GREAT CAUCASUS (4)

Fig. 1 shows the curves of the average magnitude of subsidence of the Russian Platform and the surrounding geosynclines during the Hercynian and the Alpine cycles. Here the difference in the scale of movements is of interest[3,4,7]. If the average magnitude of subsidence or uplift be referred to a unit of absolute time (a million years[2]), the average rate of vertical movements will be obtained[3,4]. Fig. 2 presents the curves of the average rate of subsidence of the Russian Platform, Uralian and Caucasian geosynclines; an examination of these will show that there is some parallelism and a similar periodicity in the movements of these different tectonic zones, the rate of subsidence on the Hercynian and particularly the Alpine platform having been considerably slower. Both the downward and the upward movements on the platform were somewhat retarded as compared to the movements of the adjacent geosynclines of the same age[4,7].

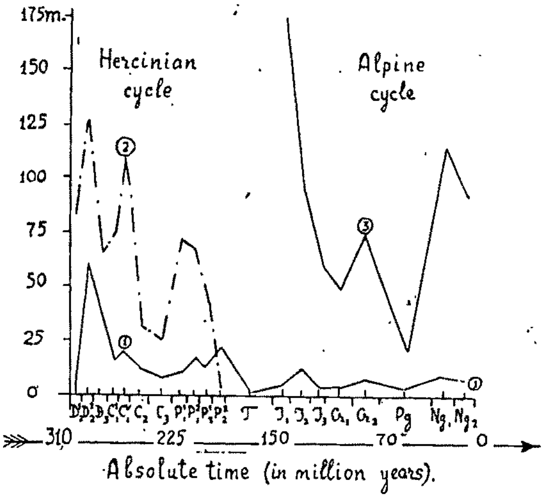

Fig. 2. CURVES SHOWING THE AVERAGE RATE OF SUBSIDENCE OF THE RUSSIAN PLATFORM (1) AND GEOSYNCLINES OF THE URALS (2) AND GREAT CAUCASUS (3), IN METRES PER MILLION YEARS

An estimation of the total volume of the rocks is made with the aid of isopachous maps. The volumes of terrigenous, carbonate, continental and volcanogenous rocks are measured by means of specially prepared isopachyte (equal thickness) maps separately for each of the rock types listed[4,6].

It is often impossible to measure the area from which the clastic rocks have been removed, since the region of the ancient erosion is overburden under younger deposits. In these cases we study the ratio of the volumes of terrigenous rocks (V_1), removed from the region of uplift, to the total volume of rocks (including effusives) (V_2), accumulated in the surrounding regions of subsidence during the same time interval.

This ratio, named the 'uplift coefficient' (δ), in the first approximation is equal to the relation between the volume of uplifts to the volume of subsidences of the earth's crust:

$$\delta = \frac{V_1}{V_2} = \frac{\text{uplift}}{\text{subsidence}}. \qquad (1)$$

Studying in this way one division after the other, we find the changes of δ in the course of time. In many cases this is sufficient to make it possible to draw important conclusions regarding the development of epeirogenic movements[4].

Since we refer the volume of terrigenous rocks to the total volume of all rocks, the ratio can never exceed unity. Hence it is not possible in this way to determine the cases when the volume of uplifts exceeds that of subsidences. However, such cases do exist, and it is necessary to have some means of determining them. With this object in view, a correction to a change of facies is introduced. If the total of uplifts exceeds that of subsidences, the amount of material removed is greater than the corresponding space in the areas of subsidence, and the surface of sediments in the zones of accumulation is raised. The additional volume of rocks obtained as a result of rise of the level of sediments (v) is subtracted from the total volume of rocks. The correction (v) but with the opposite sign is used when a lowering of the surface of sediments (a deepening of the basin) has occurred during this time interval:

$$\delta = \frac{V_1}{V_2 \pm v} = \frac{\text{uplift}}{\text{subsidence}}. \qquad (2)$$

Fig. 3 shows the changes of the uplift coefficient (δ) in the Uralian geosyncline from the Cambrian to the Permian. We see that the curve records two large cycles of epeirogenic movements (Caledonian and Hercynian), upon which second order cycles are superimposed. The beginning of each large and small cycle is characterized by a predominance of uplifts; at the middle, subsidences become prevalent; and at the close of a cycle, the significance of uplifts of the earth's crust again increases. An analogous curve has been obtained for the Caucasian geosyncline[4].

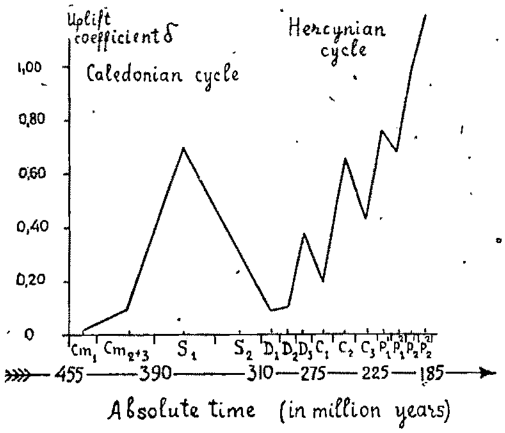

Fig. 3. CURVE SHOWING THE RATIO OF UPLIFTS TO SUBSIDENCES IN THE URAL GEOSYNCLINE

An important part in quantitative estimations is played by the determination of the boundaries of the territory actually studied. Since the volumes of clastic rocks are taken into consideration, all the areas which have supplied terrigenous material in this particular case are automatically included in the territory studied.

I have also used the volumetric method for a quantitative study of the Hercynian volcanism in the Urals[5] and of the history of sedimentation within the European part of the U.S.S.R.[6]. As a result, a number of regularities have been established which so far have escaped detection by the usual methods of geological investigation.

PSYCHOLOGISTS IN THE ASSOCIATION OF SCIENTIFIC WORKERS

THE Section of Psychology, lately formed inside the Association of Scientific Workers, met for the first time at Bedford College, London, on January 18; in the chair was Mrs. Winifred Raphael, of the National Institute of Industrial Psychology. The speakers were Miss I. M. Dunsdon, Dr. H. J. Eysenck, Miss Pearl King, Prof. T. H. Pear, Mrs. Raphael, Dr. J. D. Sutherland and Dr. Stephen Taylor, M.P. All the papers were followed by discussion. Until this meeting, psychologists had met within the Association of Scientific Workers as part of its Medical Section. The establishment of a Psychological Section has resulted in a considerable increase in the number of psychologists joining the Association (117 up to the time of writing).

The chief subjects emphasized were the relations between psychologists and other professional workers, and the ways in which psychologists may make practical contacts with others and contribute usefully from their sphere of knowledge. There is an obvious division between fields in which psychologists can make an immediate contribution, and those in which they might help after research into specific problems has been conducted. It was felt that a subject of international importance is "channels of communication", for example, the Press, radio, films, etc. An investigation into this subject is in progress.

It was urged that the Association of Scientific Workers might consider putting forward a more definite policy with regard to the results of recent scientific research, such as the atomic bomb and other revolutionary weapons of war. Certain psychologists specially interested in the subject could help by advising upon ways of 'getting ideas across' to the public.

The primary responsibility of psychologists as such is to work whole-heartedly for the advancement of their science. To-day in most sciences comparatively little can be done by individual workers, and the importance of co-ordinated research here as elsewhere was stressed. The time may even have come for university departments of psychology to establish a co-ordinating body so that (1) research workers can know what others are doing at present in their field and thus avoid duplication, and (2) plans for research into fundamental problems can be developed.

An urgent need is to let the public—at present badly instructed—know what psychology can and cannot do. More use could be made of the ordinary media of communication by psychologists who can express complicated ideas simply and clearly; but this might require a changed attitude upon the part of some editors.

Dr. Stephen Taylor discussed the possibilities and conditions of employment of social psychologists in the public services.

Dr. J. D. Sutherland considered "Relations between Psychologists and Other Professional Workers". Such relations, where they exist, are on the whole good. Probably the oldest and closest is in the educational field, because of its more obvious psychological implications. He deplored the fact that as yet there seems to be almost no co-operation between psychology departments and university authorities in the problems of selecting and training university students.

In the industrial field, relations are good, partly because only progressive industrialists ask for

psychological advice. Psychological work in the Forces has improved relations with Government services. Co-operation with trade unions is unsatisfactory, but it is hoped that the Association of Scientific Workers will now improve matters. In medicine, relations are becoming increasingly better. Co-operation with social scientists, however, is not what it might be.

Dr. Sutherland suggested that methods of recruitment of psychologists and their training for 'real life' could be improved, also that university psychology departments might assume more practical responsibilities concerning students' careers. There is a need for good popular literature on psychology. Very few intelligent members of the lay public, he said, know any names of psychologists other than Freud, Jung and Adler.

Miss Dunsdon, reporting on "A Survey of the Fields of Employment of Psychologists", described a questionnaire to be circulated to all psychologists in the British Psychological Society. The object of this survey is to obtain information concerning psychologists' working conditions, their hours, salaries, holidays, facilities for research, etc.

Dr. Eysenck presented a report on the facilities for training psychologists, based on a circular sent out by the British Psychological Society in 1944. It indicated that the following developments are needed: (1) more psychology departments in universities, (2) adequate equipment, laboratory and library facilities, journals, copies of tests, etc., (3) better staffing, (4) more stress on social psychology, (5) developments making it easier to specialize, in particular by giving practical, clinical and other facilities, (6) revision of some qualifications for admission to universities.

T. H. Pear

CROSBY HALL, LONDON

In the summer of 1946, after several years of war service as a training centre for the Women's Royal Naval Service, Crosby Hall was re-opened by the British Federation of University Women as an international hall of residence and club-house for university women. Fortunately, the beautiful fifteenth-century Hall was comparatively little damaged by bombs; and although the residential quarters were considerably injured by blast it was possible to restore them without actual re-building.

The Hall, as in pre-war days, has again become a centre for international culture and friendship, where university women from all over the world can live and study, meet and exchange views, go for short visits or use the club facilities provided. In these few months women of thirty-two different countries, from China to Paraguay and from Iceland to South Africa, have stayed here. British women are able to use the Hall for permanent residence or visits in just the same way, and although there is no fixed rule as to proportions between overseas and British residents, there usually seems to be a happy balance. Research and post-graduate students have first claim to residence. Second 'priority' is given to members staying for short visits on business or pleasure. The first Council meeting of the International Federation of University Women to take place since the War was held at Crosby Hall last summer, and no more appropriate event could have marked the re-opening. The third group of 'priorities' is that of graduates employed in London.

The Great Hall, with its magnificently carved oaken roof, its stonework tracery and tall oriel window, dates from 1466, and is of much historic interest. Originally a part of the city mansion of Sir John Crosby, it was taken down stone by stone and re-erected on Chelsea Embankment. In 1927 the British Federation of University Women, which had succeeded in raising £50,000 for the purpose of acquiring the Hall and building a residential wing, opened Crosby Hall as an international residence and club-house. It is especially fitting that the building should be on the site of the Chelsea home of Sir Thomas More, the great scholar whose circle of friends included men of learning from all over Europe, and who scandalized his contemporaries by insisting that his daughters should have the same education as his son.

Even before the War it was clear that the accommodation at Crosby Hall was not sufficient to meet the demand. The first residential wing had only been a part of the original building plan, and early in 1946 an appeal was launched to complete the scheme by building a second wing, a library and additional common-rooms. At the same time a Fellowship Fund was started in order that many university women who would most benefit by residence at Crosby Hall should not be debarred through lack of means. A special appeal to schools was made at the beginning of the year. An Association has just been started, under the title of "Friends of Crosby Hall", to link together those who are interested in Crosby Hall and concerned to see that this beautiful building is cared for, used and loved. The small subscription, which goes towards the maintenance and extension of the building, also entitles the member to lunch in Hall and to invite guests. Quite apart from this Association, the Warden of Crosby Hall will always be glad to show school and college parties—or individuals—over the Hall by arrangement.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, April 14

Farmers' Club (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Mr. H. H. Nicholson: "The Problem of Land Drainage".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. J. G. Milton: "Research and New Developments in Water Treatment".

Society of Chemical Industry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. R. P. Linstead: "Chemistry and Autarchy".

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.15 p.m.—Mr. J. C. E. Strong and Mr. C. A. Wright: "The Measurement of Surface Finishing"; Mr. J. A. Yates: "Automatic Control of Specific Gravity".

Tuesday, April 15

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Prof. T. S. Simey: "Social Welfare in the West Indies".

Society of Chemical Industry, Agriculture Group (in the Physical Chemistry Lecture Theatre, Royal College of Science, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. N. Pizer: "The Advisory Chemist and Problems in Crop Production".*

British Society for International Bibliography (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 3 p.m.—Dr. B. M. Crowther: "The Use of the Universal Decimal Classification in Periodical Abstracting Services for Scientists and Engineers".

Institution of Mining and Metallurgy (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Major-General A. J. Orenstein: "The History and Prevention of Silicosis, with special reference to the Witwatersrand" (First Sir Julius Wernher Memorial Lecture).*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. Linford Rees: "The Physical Constitution in Mental Illness".*

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Does Standardization Conflict with Progress?" (to be opened by Mr. J. W. Dalgleish).

Illuminating Engineering Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Papers dealing with Problems associated with Searchlights (Visibility, Photometry, Design. etc.), followed by a Discussion.

Institution of Structural Engineers, Lancashire and Cheshire Branch (in the Reynolds Hall, College of Technology, Manchester), at 7 p.m.—Mr. F. L. King: "Stress Recording in Bridges and Stresses due to Impact".

Sheffield Metallurgical Association (at 198 West Street, Sheffield), at 7 p.m.—Mr. John L. Rait and Mr. H. W. Pinder: "Origin and Constitution of certain Non-metallic Inclusions in Steel".

Wednesday, April 16

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W.C.2), at 3.30 p.m.—Dr. James Craigie, F.R.S.: "Relationships of Virus and Host-Cell, with reference to Latent and Cryptic Infections" (Imperial Cancer Research Fund Lecture).

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Brigadier R. A. Bagnold, F.R.S.: "Experimental Work on the Movement of Coastal Sands and Shingles".

Manchester Statistical Society (at the Reform Club, King Street, Manchester), at 5 p.m.—Prof. A. Bradford Hill: "Medical Statistics".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Rt. Hon. Oliver Lyttelton, M.P.: "Economic Reconstruction, 6. Production".

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. A. Burke, Mr. R. C. Cuffe and Mr. W. O'Neill: "Record of Experience on the Irish Electricity Supply System".

Institution of Production Engineers, Sheffield Section (at the Royal Victoria Station Hotel, Sheffield), at 6.30 p.m.—Mr. C. P. Tupholme: "Stainless Steels".

Society of Chemical Industry, Food Group (joint meeting with the London and S.E. Counties Section of the Royal Institute of Chemistry, at the Wellcome Research Institution, 183 Euston Road, London, N.W.1), at 6.30 p.m.—Dr. D. W. Kent-Jones: "Modern Trends in Cereal Chemistry in America and Elsewhere".

Society of Dyers and Colourists, Northern Ireland Section (at Queen's Hotel, Belfast), at 7.30 p.m.—Annual General Meeting.

Thursday, April 17

Royal Society of Arts, India and Burma Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. Hugh G. Rawlinson: "The Influence of India upon European Culture".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. R. Baker: "Is the Cell-theory True?"; Dr. P. H. Gregory: "The Biology of the Air".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. P. A. Hufton: "Testing Civil Aircraft".

Society of Chemical Industry, Road and Building Materials Group (at 1 Grosvenor Place, London, S.W.1), at 6 p.m.—Mr. W. P. Andrews: "Modern Road Construction in Concrete".

Chemical Society and the Royal Institute of Chemistry (joint meeting of the Manchester Sections, at the Engineers' Club, Albert Square, Manchester), at 7 p.m.—Mr. A. H. Baines: "Recent Work in Colour Photography".

Royal Photographic Society, Scientific and Technical Group (at 16 Princes Gate, London, S.W.7), at 7 p.m.—Dr. G. W. W. Stevens: "Some Optical Complications of Graticule Production".

Pharmaceutical Society, Manchester, Salford and District Branch (in the Council Chamber, Houldsworth Hall, Manchester), at 7.45 p.m.—Annual General Meeting.

Chemical Society (at Burlington House, Piccadilly, London. W.1).—Discussion on "Electrolytic Solutions".

Wednesday, April 16—Thursday, April 17

Institution of Mining Engineers (joint meeting with the Institution of Mining and Metallurgy, at the Royal Institution, 21 Albemarle Street, London, W.1).—Conference on "Silicosis, Pneumokoniosis, and Dust Suppression in Mines" (to be opened by the Rt. Hon. Emanuel Shinwell, M.P.).

Wednesday, April 16

At 10.30 a.m.—First Session; at 2.30 p.m.—Second Session.

Thursday, April 17

At 10.30 a.m.—Third Session; at 2.30 p.m.—Fourth Session.

Friday, April 18

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—Mr. Arnold Emerson and Mr. L. W. Berry: "Experiments in the Lithgow Propeller Tunnel".

Society of Chemical Industry, Birmingham Section (joint meeting with the Plastics Group, at the Chamber of Commerce, Birmingham), at 6.30 p.m.—Prof. H. Staudinger: "Vinylidene Chloride and its Polymers".

Society of Dyers and Colourists, Manchester Section (in the Lecture Theatre, Gas Department Showrooms, Manchester), at 6.30 p.m.—Dr. G. L. Royer: "Rayon Dyeing".

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 6.30 p.m.—Annual General Meeting; at 7 p.m.—Mr. D. O. Sproule: "Material Testing by Supersonics".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturers in Science (3, men or women) in the Training Department, with emphasis respectively on Botany, Physics and Chemistry—The Warden, Goldsmiths' College, New Cross, London, S.E.14 (April 15).

Lecturer in Industrial Administration—The Registrar, College of Technology, Manchester 1 (April 15).

Senior Lecturer in Mechanical Engineering—The Registrar, College of Technology, Manchester 1 (April 15).

Chief Examiner (Chemist, male), and a Senior Examiner (Chemist, male), in the Ministry of Supply—The Ministry of Supply (Est. 5 C), Leatherhead, Surrey (April 16).

Deputy Public Analyst, and a Senior Assistant Analyst (male)—The Clerk of the County Council, County Buildings, Stafford (April 17).

Principal—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (April 18).

Officers (2) to take charge of the maintenance of experimental animals—The Director, Genetics Laboratory, Institute of Animal Genetics, West Mains Road, Edinburgh 9 (April 19).

Assistant Experimental Officers (2) to assist in experimental work on breeding and selection of small animals (insects)—The Director, Genetics Laboratory, Institute of Animal Genetics, West Mains Road, Edinburgh 9 (April 19).

Head of the Engineering Department—The Principal, County Technical College, Dartford, Kent (April 19).

Educational Psychologist—The Director of Education, Education Offices, Leeds 1 (April 21).

Professor of Child Health—The Secretary and Registrar, The University, Bristol (April 21).

Lecturer in Biology and Horticulture at the Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (April 21).

Lecturer in Physics—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (April 21).

Assistant Lecturer in Geography—The Registrar, The University, Manchester 13 (April 24).

Lecturer in Mathematics—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (April 25).

Entomologist to carry out a survey of the tsetse areas of the Southern Sudan and undertake research work—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Veterinary Entomologist' (April 28).

Assistant Masters (qualified, graduate) for Science (to Higher School Certificate), and Geography (to Higher School Certificate), at the Duke of York's Royal Military School, Dover—The Under-Secretary of State, War Office (A.E.1), 45 Eaton Square, London, S.W.1 (April 28).

Professional Officers in the Tobacco Branch of the Department of Agriculture, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (April 30).

Lecturer in Surveying in the Mining Department—The Registrar, The University, Leeds 2 (April 30).

Lecturer in Geology at the Natal University College, Durban—The Secretary, Universities Bureau of the British Empire, 24 Gordon Square, London, W.C.1 (April 30).

Junior Professional Officer (woman) in the Branch of Botany and Plant Pathology, Department of Agriculture, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (April 30).

Readership in Chemical Engineering tenable at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Professor of Preventive Medicine—The Registrar, The University, Manchester 13 (April 30).

Lecturer in the Economics of Colonial Agriculture—The Registrar, University of Oxford, Oxford (April 30).

Assistant Lecturer or Lecturer (*a*) in Applied Mathematics and (*b*) in Statistics—The Registrar, The University, Leeds 2 (April 30).

Assistant Lecturer in Botany—The Registrar, The University, Leeds (April 30).

Research Officer (Ceramics Research) at the School of Mines, Adelaide—The Secretary, Australian Scientific Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1212 (May 3).

Officer-in-Charge, Instruments Section, Division of Aeronautics, Melbourne—The Secretary, Australian Scientific Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1213 (May 3).

Research Officer, Division of Entomology, Canberra—The Secretary, Australian Scientific Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1218 (May 3).

Readership in Civil Engineering tenable at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 6).

Lecturer in Metallurgy—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Assistant to the Advisory Bacteriologist—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8.

Assistant Fuel Technologist for the Plant Engineering Division—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Plant Engineering Division'.

UNIVERSITY DEVELOPMENT IN GREAT BRITAIN

THE need for more effective organisation in the universities of Great Britain for the interchange of views at all levels and in all the fields concerned has been recognized in the Barlow Report and also in reports from the Parliamentary and Scientific Committee, Association of University Teachers and other bodies. The last report from the Parliamentary and Scientific Committee suggested that the annual conference of representatives of the different universities and of the Association of University Teachers might well provide the basis for some such more permanent and active means. If this conference set up standing committees and invited specialist advice from outside the universities, it might become the active and influential consultative body which has long been needed in university affairs, and to provide which a Universities Council had previously been recommended by the Parliamentary and Scientific Committee as well as by the Association of University Teachers.

Such a joint meeting did, in fact, take place in September 1946 at the invitation of the Committee of Vice-Chancellors and Principals, and it is understood, according to Sir Ernest Simon, that a similar representative universities council will meet this year. This is a step in the right direction, and it is important because, although the Government has already announced new and extended terms of reference for the University Grants Committee, the ambitious programme of university expansion visualized in the Barlow Report on Scientific Man-power and in the report of the Parliamentary and Scientific Committee can only succeed if there is collaboration in shaping policy all the way through the university world. Moreover, if such expansion is to take place without loss of independence on the part of the universities, and the University Grants Committee is to exercise more positive functions, the universities must evolve a satisfactory organisation of their own.

For this reason "A Note of University Policy and Finance in the Decennium 1947–56", which was prepared in July 1946 by the Committee of Vice-Chancellors and Principals, in order to present to the University Grants Committee the collective views of the vice-chancellors of British universities on certain important issues, both of policy and finance, which seemed to arise from the succession of official reports dealing with various aspects of university activity, is a document of outstanding interest and importance. According to a statement by Sir Hector Hetherington, chairman of this Committee, published in the *Universities Quarterly* of February, the note is not a private document, and copies have been furnished to each university for distribution and use as might be thought fit. The first part of the note deals with questions of administration. Part 2 deals with finance, and concludes that the proportion of university income to be found from Government services will be increased from roughly one third to three quarters in the next few years. Part 3 discusses the future relations of the Government and the universities in Great Britain.

In this part of the note it is stated that the universities entirely accept the view that the Government has not only the right, but also the duty, of satisfying itself that every field of study which in the national interest ought to be cultivated in Great Britain is in fact adequately provided for in the university system, and that the resources which are placed at the disposal of the universities are being used with full regard both to efficiency and to economy. In the view of the vice-chancellors, therefore, the universities may properly be expected not only individually to make proper use of the resources entrusted to them, but also collectively to devise and execute policies calculated to serve the national interest. In that task, both individually and collectively, the universities would be glad to have a greater measure of guidance from the Government than until quite recent days they have been accustomed to receive.

Pointing out that from its foundation the University Grants Committee has exercised a positive influence on the policy of every university, the note states that in the last twenty years probably no university has undertaken any important development without full consultation with the Committee and its officers. The universities have always recognized that inevitably and rightly the Committee has the duty, in its financial decisions, of basing its judgment on the merits of their policies. Hence the vice-chancellors would be glad if the University Grants Committee were formally authorized and equipped to undertake surveys, in all the main fields of university activity, designed to secure that as a whole the universities are meeting the whole range of national need for higher teaching and research.

The vice-chancellors emphasize their belief that it is common ground that the universities should continue to be in the fullest sense of the word self-governing societies, accountable for what they do or fail to do, properly subject to criticism, and affected in their fortunes by the public judgment of their policies; but in the last resort, their own masters. The fundamental duty of the university teacher, in his own field of study and inquiry, to pursue and to communicate with the utmost objectivity such measure of truth as he can attain, and the importance in a free society of safeguarding that fundamental truth from any risk of abridgment, are well stressed. While, however, the University Grants Committee will need to call upon the services of many experts in different fields and to add to its secretariat and even to the number of its whole-time stipendiary members, the vice-chancellors do not wish to see any fundamental change in the size or character of the Committee. The Committee is probably already near the limit of numbers for an effective working body, and the vice-chancellors believe that it will best serve its purpose if it continues to be composed as at present largely of members of distinguished academic experience selected for their personal fitness, and not in a representative capacity, giving part-time service for a period of years. An acceleration of techniques already in some degree in operation is regarded as the primary need.

An addendum from Sir Richard Livingstone, who was not present at the discussion on this part of the note, records his own view that the University Grants Committee should survey the university system of Great Britain in order to secure that the universities of the country cover the necessary fields of study, so that the Committee might give such advice to the universities as it believes necessary. With this help, Sir Richard thinks that the universities can and should be trusted to take such measures as the interest of the country and the needs of learning and education dictate.

From one point of view, this part of the vice-chancellors' note, although the shortest, is the most important; but there are certain points in the preceding sections which deserve to be noted also. Starting from the report of the Barlow Committee, the vice-chancellors comment on the divergence between claims upon university man-power presented by the Hankey and by the Barlow Committees. While the universities are both willing and ready to meet, to the best of their ability and from the resources made available to them, both new and increased demands, provided the demands are in the national interest and are not incompatible with activities appropriate to the university field, they are not in a position to judge finally as to the order in which priorities would best accord with the nation's needs; nor can they estimate, on a long-term plan, how far demands upon them put forward as immediately necessary are likely to remain permanent. On the need for doubling the pre-war number of graduates in science, the vice-chancellors hold that in no single university should a great increase in one major faculty be unaccompanied by corresponding increases in the other major faculties. Again, in insisting upon the need for such balance in expansion, the vice-chancellors also observe that the improvement of the universities requires a first place in the programme of educational expansion; and they are reserved on the question as to whether there is a sufficient proportion of innate ability in the population to provide double the pre-war number of students able to profit by a university education. The provision for expansion, in their view, would best be made by expanding existing institutions properly rather than by founding a new university, at least in the first decade.

The second and longest part of the vice-chancellors' note is that dealing with finance. This covers both capital outlay and recurrent expenditure, as well as discussing the necessary priorities in man-power and materials. The capital aggregate of the needs reported by each university to the University Grants Committee in March 1944 was £28 million on a 1938–39 basis of costs, a figure for which the vice-chancellors now provisionally substitute £45 million, or, translated into 1947 probable building costs, something of the order of £80 million, to be spent by the end of the decade 1947–56. For this purpose the vice-chancellors advocate the creation of a Treasury fund, secured by the Government in advance to the

University Grants Committee, so that the universities shall know definitely what capital outlay they each can make during the first five years of the decade, and approximately what further capital outlay they can make collectively during the second five years. The apportionment of this latter sum among the universities should be made by the University Grants Committee before the second quinquennium arrives.

This method of capital finance is urged by the vice-chancellors independently of the level at which expansion takes place, and they also press as essential for continuous development adequate priorities in building material, man-power for building and licences, *pari passu* with the national housing programme in 1947. Private benefactions can only form a small percentage of the total capital now required by the universities for sites, buildings and permanent equipment. As regards recurrent expenditure, the vice-chancellors consider not only the call for expansion but also the incidental factors such as the increased cost of equipment and materials for teaching and research, both books and apparatus, the need for upward revision of salaries, the increased expense of halls of residences, and, as already indicated, they reach the conclusion that if the universities are to meet the national needs of the decade, their pre-war combined annual revenue must be trebled; and of this total revenue, three quarters will have to be found from Government sources by way of the University Grants Committee.

In a written reply in the House of Commons on March 10, the Chancellor of the Exchequer stated that he proposes to resume the pre-war practice of settling Exchequer grants to the universities for periods of five years, and that Parliament will be asked to provide recurrent grants rising from £9,000,000 for the academic year 1947–48 to £9,970,000 for 1948–49, and then by annual increments to £11,920,000 for 1951–52. These figures exclude the grant of £500,000 now made to teaching hospitals, the amount of which for future years has not yet been determined, and they also exclude grants for agricultural education, responsibility for which will pass to the University Grants Committee after the current year. The Chancellor has also accepted the estimate of that Committee for non-recurrent grants during the quinquennium of £40 million for new buildings and £10 million for sites, existing buildings and new equipment. The Chancellor stated that he will do his best to meet the stimate; even allowing for a high degree of priority, however, the Minister of Works considers that universities will be unable to undertake more than 20 million of new buildings during the quinquennium.

This reply shows that the Chancellor is prepared to go a fair way to meet the views expressed by the vice-chancellors in their note, and further evidence of his general attitude is provided in a letter to Sir W. W. Wakefield, deputy chairman of the Parliamentary and Scientific Committee, concerning its eport on "Universities and the Increase of Scientific Man-Power". Mr. Dalton believes that that report under-estimates the number of scientific workers who will be available in 1955 and 1965, and over-estimates the number of retirements in the second decade. The Chancellor estimates that there will be 104,000 scientific workers by 1965, after allowing for the loss of 18,000 from retirement and 5,000 from choice. Again, he doubts the practicability of effecting university expansion to the extent suggested in that report or in that of the Barlow Committee, and accepts rather the estimate, based on investigations made by the University Grants Committee, of 88,000 as the maximum number of science graduates in the next ten years if academic standards are not to be lowered.

The Chancellor also indicated that he shared the views of the Parliamentary and Scientific Committee and also of the vice-chancellors on the inadvisability of founding a new university at this stage. He is in sympathy with the upgrading of some university colleges to university standard, and is clearly open-minded on the question of developing several universities out of constituent colleges of the University of London. He is dubious as to the wisdom of bringing certain technical colleges to university standard, and does not agree with the Parliamentary and Scientific Committee that existing salary scales will be a deterrent to the recruitment of university teachers.

While this letter makes evident the anomaly in the higher educational system of Great Britain, which places the development of universities and colleges of technology under different ministers, the Chancellor's observations are distinctly encouraging and promise all that could be expected at the moment. Furthermore, the vice-chancellors' note shows that there is full support within the universities for the action the Government has already taken in extending the functions of the University Grants Committee. This frank recognition of the necessity of some over-all attempt to plan the resources and expansion of the universities in accordance with national needs, broadly understood, is accompanied by the statement that the vice-chancellors would not exempt the universities themselves from the necessity of playing their own part in the co-operative planning of the whole university system. It falls to them, at least as much as to the University Grants Committee, to devise methods of working together to ensure the fulfilment of their common task. Some matters call for central discussion on the national scale, while others are best dealt with regionally. There are also the important and complex relations with the Dominion universities, with the higher educational service of the Colonies and with the universities of the United States and of Europe.

The vice-chancellors have recently appointed two committees, drawn from experts in particular problems outside the membership of the Committee, to report on matters of general consequence to the universities. Other similar studies will be undertaken as speedily as conditions allow. In this way and in others, the vice-chancellors hope that the universities of Britain will be able to co-operate with one another and with the University Grants Committee in the planning and development of a full range of university service.

It seems clear, therefore, from this note that the universities are prepared to participate in planning their future expansion and development, and that they are also unanimous that the Committee of Vice-Chancellors and Principals should play the part of a national negotiating body in which they have full confidence. The Committee is also understood to be inquiring at the present time into the whole question of halls of residence for the modern universities; and it should also be noted that the universities have already been asked to quadruple their grants to the Universities Bureau of the British Empire, a body which finances the Committee of Vice-Chancellors and Principals and provides its secretariat.

Clearly the Committee cannot work without a strong secretariat, as was pointed out by Sir Ernest Simon in his pamphlet "The Development of British Universities" three years ago, and as has since been emphasized by the Parliamentary and Scientific Committee in its latest report.

Some of the proposals for expansion of the individual universities and suggestions for the establishment of new universities, at least as currently reported in the Press, appear to show little appreciation of the importance of planning the national resources for university development to the best general advantage. That manifestly is the desire and intention of the vice-chancellors and of the Chancellor of the Exchequer; and while both have shown the desire to plan resources in this way, the statements issued assure to the universities the sole responsibility of determining trends of research and the training of scientific workers, and there is to be no interference with research funds. These statements indicate that university development in Great Britain is likely to proceed on sound lines, with sufficient Government support and without undue outside interference.

LAST TESTAMENT OF A PHYSICIST

Fundamental Theory

By Sir A. S. Eddington. Pp. viii + 292. (Cambridge: At the University Press, 1946.) 25*s*. net.

SIR ARTHUR EDDINGTON died in 1944. He left, almost completed, a manuscript entitled "Fundamental Theory". Sir Edmund Whittaker was invited by Miss Eddington and the syndics of the Cambridge University Press to supervise the publication of this manuscript in book form, and the volume under review is the result. Sir Edmund Whittaker has added to what must have been no light task by contributing to the *Mathematical Gazette* (29, 137–44, Oct. 1945) a clear introductory account of the material in the volume. Prof. E. T. Copson, of Dundee, and Prof. G. Temple, of King's College, London, have assisted Whittaker in the proof-reading. The gratitude of all who knew Eddington, either personally or through his writings, is due to the mathematicians mentioned for preserving for posterity a remarkable document, the last scientific testament of one of the profoundest thinkers of our time.

The scope of the book is not properly indicated by its title, since it does not deal with the foundations of physical science in the ordinary sense. It should have been called, perhaps, "Advanced Theory", for it assumes not merely a knowledge of, but also the actual conclusions of, the general theory of relativity and the quantum theory. Its aim is to weld the two into a single discipline, and in the course of the attempt it claims to complete what for years had been a main theme of Eddington's doctrines, namely, the calculation of the molar, microscopic and nuclear constants of Nature in terms of pure numbers, by analysis of the group-structure of the physical universe. The first five chapters reproduce almost verbatim the text of his Dublin Lectures of 1943, "The Combination of Relativity Theory and Quantum Theory" (*Dublin Inst. Adv. Studies*, Series A, No. 2), and are devoted to the uncertainty of the reference frame and what Eddington calls *multiplicity factors*; the next three reproduce in terser form the substance of his "Relativity Theory of Protons and Electrons" (Cambridge, 1936), and are devoted to an exposition of his very beautiful sixteen-dimensional non-commutative calculus, by which he claims to represent all the characteristics, mechanical, electrical and magnetic, of *particles* considered as *carriers of variates*; the remaining four chapters apply the sedenion analysis thus developed to such physical problems as the levels of the hydrogen atom, the masses of the proton, neutron, deuteron and helium nucleus, the separation constant of isobars and the mass of the mesotron, and to such more general questions as the wave equation, the electromagnetic field and radiation. As an appendix there is reprinted Eddington's paper in the Cambridge Philosophical Society's *Proceedings* (40; 1944) on the evaluation of the cosmical number N.

The volume is brilliantly written; but the physical argumentation is so unfamiliar, so involved, so perpetually under revision and correction, that it is extremely hard to extract from it any convincing proof of any of Eddington's most famous formulæ. When I say "brilliantly written", I mean that it is enlivened with sallies of a most vivid description in nearly every chapter, showing how the unregenerate Eddington kept up his spirits and his self-confidence to the very end in spite of all the criticisms he incurred; as, for example, when he writes (p. 189) "to deny that a neutron is composed of a proton and an electron is as pedantic as to deny that water is composed of oxygen and hydrogen"; or (p. 162) "broadly speaking there is no three-particle theory in physics"; or (p. 131) "the only kind of individuality known in physics is the pseudo-individuality conferred by idem-potency"; or (p. 30) "the term particle survives in modern physics but very little of its classical meaning remains"; or (p. 19) "quantisation is a distinctively *electrical* phenomenon"; or (p. 89) "the initial fallacy in recent investigations of white dwarf matter . . . continues to work devastation in astronomy"; or (p. 76) (a remark I strongly object to, as in making it Eddington was behaving like an ostrich) "the infinite universe has long been dead and buried; and those who insist on digging up the corpse must expect to be haunted".

To come to more serious criticisms. Those who seek a compact proof that the fine-structure constan $2\pi e^2/hc$ has the exact value 1/137 will have a very difficult time of it in this book. One first has to master the use Eddington makes of his multiplicity factors k, which are somewhat disarmingly defined as the number of dimensions of a certain phas space; then his procedure of *stabilization*, which i a sort of wand which he waves in order to suppres inconvenient degrees of freedom, and so to alter the multiplicity factors; then one has to overcome all one's prejudices in swallowing a formula on p. 29, that masses are *inversely* as multiplicity factors, whereas, with Eddington's repeated identification of mass with energy, one would have expected the energy of a particle to be directly, not inversely, proportional to the number of its degrees of freedom in phase space. After these troublesome preliminaries one reads to §20, entitled "The Fine-Structure Constant", only to find that there merely plausible considerations are advanced for the assignment of the number 137 to the ratio of two "atoms of action", and that the theoretical derivation of the relation is postponed to §33. Lastly, one cannot follow §33 at all. These difficulties re-occur throughout the book.

Still severer criticism must be made of one of Eddington's derivations of what he calls "the central formula of unified theory" (p. 81, equation 40.8). This is the formula:

$$M = \frac{136}{10}\,\frac{3}{4}\,\beta^{1/6}\,\frac{h}{2\pi}\,\frac{\sqrt{(4/5)N}}{\cdot cR_0},$$

where 136 and 10 are multiplicity factors, β is the "Bond factor", M is the mass of the hydrogen atom, R_0 is the radius of the Einstein spherical universe, and N $(=3/2.136.2^{256})$, the cosmical number, is the number of protons and electrons in the universe. He first derives the formula by considerations involving various fictitious particles—the standard carrier, extracules, intracules, hydrocules. These arguments I cannot follow. He then remarks: "in the next three sections the same formula will be derived by an entirely different method". This method is an application of one of his aphorisms, "exclusion is a wave-mechanical substitute for gravitation", and one's spirits begin to rise, because the method consists in applying to the *uranoid*, or neutral Einstein universe, the Pauli exclusion principle as used, for example, in the Thomas–Fermi atom, or in the determination of the equation of state of a degenerate gas, as applied to super-dense stars, and with this, at least, an astrophysicist is familiar. Eddington does, in fact, apply the usual method, of filling cells in phase space, and one expects to see the 'central formula' emerge. Unfortunately for Eddington's aphorism, it emerges with the wrong power of N, in fact with an extra unwanted factor $N^{1/3}$, which makes nonsense of the so-called independent derivation. But Eddington is not one whit abashed. He calmly puts $\mu_1 = \mu_0(\frac{3}{4}N)^{1/3}$, where μ_0 is the mass-constant of an extracule, and presents us with a formula, (41.41), supposed to be equivalent to the central formula, but with the unwanted power of N absorbed into one of the symbols. It is difficult to understand how Eddington could convince himself that this palpable fudge amounts to an independent proof of his 'central formula' by the 'gravitation equals exclusion' principle. But when Eddington had the bit between his teeth, no mere mathematical inconsistency ever held him back: witness, for example, his erroneous treatment of stellar opacity, as I have shown elsewhere.

Eddington's 'uranoid' plays the same part in his theory as the 'substratum' in kinematical relativity. In both theories it is an idealized model of the smoothed-out universe, and as such is the environment, the scene, the stage upon which phenomena are enacted or objects isolated. But whereas the substratum unchangingly incorporates the essential element of expansion, or recession, Eddington's uranoid is static—non-expanding and at zero temperature. Eddington admits (p. 93) that both his uranoid and another environment he introduces called 'the planoid' "differ widely from the actual expanding universe". Eddington has been, in fact, inclined to criticize notions which competed with his own, and then, no doubt unconsciously, develop similar notions in his own work. Another example: on p. 14 he correctly explains that by adopting two conventions as to units, namely, $c = 1$ and $8\pi\kappa(h/2\pi)^2 = 1$, he is left with one unit at his disposal, "which may be taken to be a length, mass, density or any other combination". "If, for example, it is taken to be a length", every physical quantity has a single dimension index which shows how it varies with the unit of length. But why did he not go on to admit that it might be taken to be a *time*? Why did he unsparingly criticize and reject my own similar procedure when I made physical quantities depend only on the unit of time?

His actual reason for taking $c = 1$ is perverse and misguided: "by taking the velocity of light to be unity, we avoid the obsolete and troublesome distinction between mass and energy" (p. 14). It is as though one should justify measuring pressures in centimetres on the ground of avoiding the obsolete and troublesome distinction between pressure and length. The treatment of energy as mass obscures the fundamental fact that energy has to be defined through mechanical work, and the whole theory of the momentum-energy 4-vector shakes visibly as soon as we see that energy is really a 4-scalar, as is necessary (among other reasons) for the conservation of energy to have a meaning.

Leaving aside these criticisms of detail, one has to pass some general judgment on the work as a whole. It must be recognized that Eddington has invented a mathematical technique, a logic of reasoning and a language of formulation which are as yet strange to most of us, and which no doubt conceal arguments and considerations which would be accepted if less individually expressed. That his work runs counter to some of current physics he was well aware. The antagonism is evident from the outset of the book (p. 9), for he treats the non-Coulombian energy of two electrical particles as Ae^{-r^2/k^2}, while on Yukawa's formulation and on kinematic relativity exponential terms of the type $e^{\pm e^2/mc^2r}$ are involved (*Phil. Mag.*, 34, 244; 1943). Thus the whole use which he makes of the Gaussian theory of errors is out of line with current electrical theory. Nevertheless, the agreements he gets with the observed constants of Nature are impressive, though (to my mind) calculating the recession-speed of the galaxies is only equivalent to calculating the age of the universe at the moment we happen to be viewing it. I think that Eddington's repeated insertions of lists of constants calculated from 'fundamental theory' were made more to convince his critics than because he himself attached over-riding importance to them. It was the landscape of his theory that most appealed to him. Witness, for example, his beautiful geophysical analogy (p. 220): "The term uranoid was derived from analogy with the geoid; the field momentum and energy is the isostatic compensation of the mountains (object particles) added to the uranoid. We have not hitherto used this analogy because geodesy is not accustomed to deal with mountains which are 'unidentified members of a large assembly'. But we are now preparing, formally at least, to deal with individual mountains; and an important step is as far as possible to attach to each individual its own isostatic compensation, instead of the collective compensation that suffices in scale-free physics. . . . The wave-function is a self-contained unit which can be dumped anywhere on the uranoid without upsetting the equilibrium of the uranoid particles."

Eddington's last scientific testament has all the marks of the production of a man of genius, not excluding tiresomeness; whether or no it will survive as a great scientific work, it is certainly a notable work of art. E. A. Milne

TECHNICAL AND SCIENTIFIC ASPECTS OF ATOMIC ENERGY

Science News, 2

Atomic Energy Number. Edited by Prof. R. E. Peierls and John Enogat. Pp. viii+168+15 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1947.) 1s. net.

MUCH has appeared in print and been heard in recent weeks about atomic energy; but an authoritative survey of the technical and scientific development of the past few years in the field of nuclear physics is still lacking. The second volume of Penguin Science News is, therefore, very welcome, because it is a collection of seven articles, written by prominent nuclear scientific workers, covering some of the more important technical and scientific aspects of the subject of atomic energy. The question of international control, and the political and social consequences are not dealt with specifically. The authors, some as members of the British and others of the American staff, were at one time engaged together on the atomic bomb project at Los Alamos, and thus write with first-hand knowledge of the problems which were tackled and solved in the production of atomic energy for military purposes. Each of the seven articles is self-contained and may be studied separately.

The subject-matter is presented in an interesting fashion, and can be readily understood by the non-specialist but scientific reader. The first article, by Prof. R. E. Peierls, is a general survey of the whole field and forms a key to the rest. H. A. Bethe follows with a description of the structure of atoms and nuclei, and H. L. Anderson shows how atomic power was tamed and plutonium produced. "The Physics of the Bomb", by P. Morrison, gives not only a clear description of the chain reactor which constitutes the atomic bomb, but also a very vivid picture of what happens during and immediately after the explosion. Some of the peace-time applications of the liberation of nuclear energy using radioactive tracers are dealt with by M. Argo and E. Teller, and in the final article O.R. Frisch reviews, with numerous diagrams, some of the techniques used in nuclear research.

Considering the high price of present-day scientific text-books, it is remarkable that this collection of articles can be produced for so small a cost as one shilling. It is true that the diagrams, though clear, are too small and that the plates leave much to be desired both from the point of view of subject and reproduction; but these are very minor defects in a book which, undoubtedly, will be widely read and which will be in great demand—probably in greater demand than the limited supply will be able to satisfy. S. Weintroub

D.D.T. FROM AN AMERICAN POINT OF VIEW

D.D.T. and the Insect Problem

By James C. Leary, Dr. William I. Fishbein and Lawrence C. Salter. Pp. vii+176. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 12s. 6d.

THE insecticidal property of D.D.T. was undoubtedly a great discovery, and its application during the War, at a time when the supplies of other insecticides were inadequate after the capture by the Japanese of the derris-producing areas and the cutting off of supplies of pyrethrum, was an important contribution to Allied victory. D.D.T. will have many uses in peace-time, and it is therefore important that its properties should be widely known so that it may be used to the best advantage. In Britain the book "D.D.T.: the Synthetic Insecticide" (reviewed in *Nature*, 158, 359; 1946), by West and Campbell, was generally welcomed; the authors have been themselves engaged in insecticide research, and have made important contributions to knowledge concerning D.D.T. Now a book on apparently similar lines comes from the United States. Its authors are not research workers; one is a medically qualified epidemiologist, but from internal evidence one judges that the book was mainly written by his colleagues, who are both journalists. Although the book looks at first sight as if it were a scientific compilation, it is in fact popularized journalism with some scientific data thrown in rather uncritically for effect.

D.D.T. was first used in Switzerland, and many of the 'classical' experiments were carried out in that country. Later, during the War, a great deal of experimental work was done both in the United States and in Britain. Unfortunately, the British authorities were rather more reluctant than the American to allow publication of the results of this work, so the literature contains a preponderance of American papers. Nevertheless, many important British contributions have been published. In West and Campbell's book the bibliography is reasonably complete up to 1945, when it went to press; there are many Swiss and British references, but the majority listed are American. Leary, Fishbein and Salter also publish a bibliography. It contains no references to Swiss work (they do acknowledge in the text that a little preliminary research was done in Switzerland), and the only British contributions appear to be three short notes in the *British Medical Journal* describing cases of individuals poisoned by excessive exposure or by drinking D.D.T. solutions. Every other reference is American.

Notwithstanding its trans-Atlantic bias, "D.D.T. and the Insect Problem" might still be a useful book if it were an accurate and readable summary of current knowledge. It is not. It contains many sweeping and controversial statements; thus, for example, infectious encephalitis (confusingly called "Sleeping Sickness") is definitely stated to be carried by a culicine mosquito. Its style may be gathered from a typical quotation, from the section on typhus control: "Neapolitan brides finally got so they laughed when D.D.T. replaced rice at weddings". So much first-class research has been done in the United States on D.D.T., and there are so many good 'popularizers' in that country, that it is a pity that a better book has not been produced to fill what must be a widely felt need.

Kenneth Mellanby

EXPERIMENTS ON THE STIMULATION OF CLOUDS TO PRODUCE RAIN

By E. B. KRAUS and P. SQUIRES

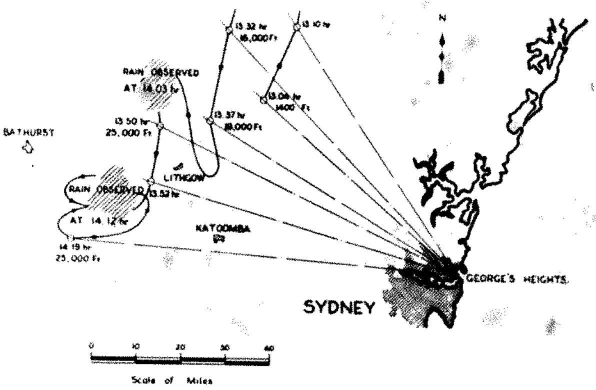
Division of Radiophysics, Council for Scientific and Industrial Research, Commonwealth of Australia

IN 1933 Bergeron[1] postulated that rain falls only from clouds which contain both water drops and ice crystals. Natural cumulus clouds at temperatures above −13° C. often contain only supercooled water drops and no ice crystals. If a method existed of planting crystal 'germs' in these clouds, the crystals would grow into large snowflakes at the expense of the water drops and eventually fall as rain or snow.

During a visit to Schenectady in July 1946, one of us had the opportunity of witnessing Schaeffer's experiments in which ice crystals were produced artificially in the laboratory by the sudden cooling of moist air[2]. These experiments can be related to a quantitative theory which has been developed by Volmer[3]. They suggested a possible method of planting ice particles in natural clouds. Newspaper reports since that date have indicated that Langmuir and Schaeffer have succeeded in stimulating the precipitation of snow from supercooled clouds by dropping 'dry ice' pellets into them from aircraft.

Experiments have now been carried out in Australia with the view of investigating the artificial stimulation of rain. At the time of writing eight different clouds have been treated. Radar observations have indicated that rain formed inside the cloud on six occasions, and on four of these heavy rain was observed visually to reach the ground. One case is doubtful; and a single negative result was obtained when a cloud, which reached only about 1,000 ft. above freezing-level, was infected. All other clouds had a vertical extent of more than 10,000 ft., of which at least 4,000 ft. were above freezing-level.

One of the most spectacular tests was carried out on February 5, 1947. On that day equatorial air was flowing slowly over the east coast of Australia from a generally north-easterly direction. Inland areas of eastern New South Wales were covered by seven- to eight-tenths of cumulus cloud (Fig. 1). The coastal plain and the Pacific were cloudless, as seen in the background on Fig. 2. The cloud base was at 11,000 ft., the freezing-level at 18,000 ft. and the top of the clouds uniformly at 23,000 ft.



RADAR PLOT OF THE AIRCRAFT TRACK AND THE TWO AREAS WHERE RAIN ECHOES WERE OBSERVED TO FORM

At 13.45 hr., 100 lb. of granulated carbon dioxide was dropped into a cloud the top of which was slightly below the general level. After five minutes, no visual results were observed. The aircraft flew on, and another test was carried out about twenty miles to the south-west. At 13.56 hr. 150 lb. of 'dry ice' was dropped into a second cloud. The aircraft circled, and in less than five minutes rain echoes from within the cloud were recorded on the aircraft's 10 cm. radar equipment. After the release of a further 150 lb. of 'dry ice', the echoes grew in intensity, and twenty-one minutes after the cloud was first infected an oblique view was obtained which showed heavy rain coming from the base of the cloud. Forty-five minutes later the aircraft descended to 8,000 ft., well below the cloud base, and a pillar of rain covering at least twenty square miles was then seen to reach the ground. Later interrogation of farmers in that vicinity confirmed the occurrence of an isolated rain storm.

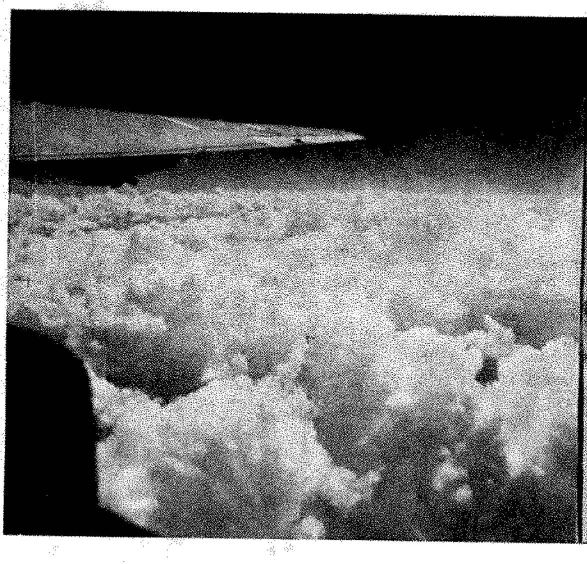


Fig. 1. INLAND CLOUD TYPES BEFORE 'DRY ICE' WAS DROPPED

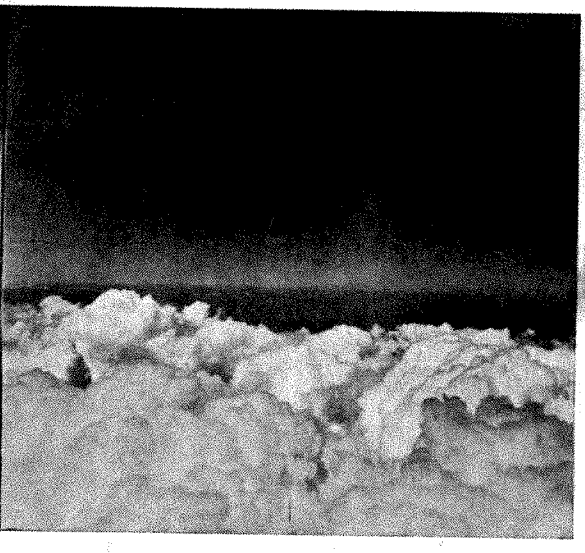

Fig. 2. GENERAL SITUATION LOOKING EAST OVER THE PACIFIC

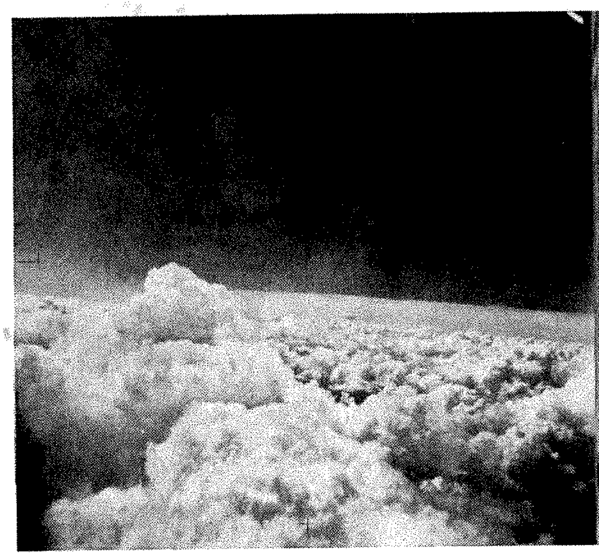

Fig. 3. NINE MINUTES AFTER THE RELEASE OF 'DRY ICE'

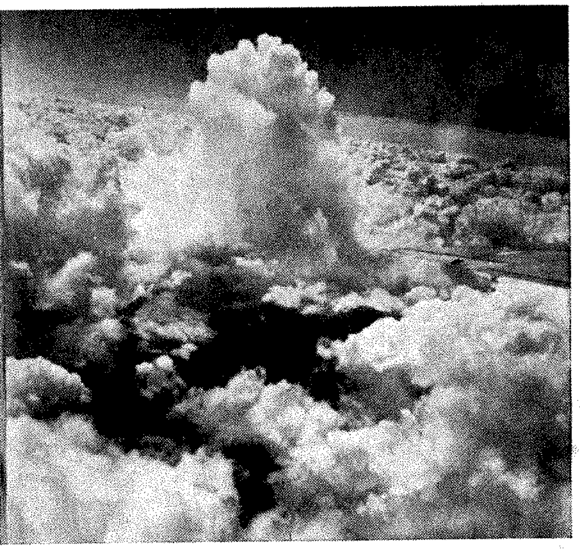

Fig. 4. THIRTEEN MINUTES AFTER THE RELEASE OF 'DRY ICE'

The flight was observed by a 25 cm. radar set at George's Heights in Sydney. The accompanying radar plot gives the measured position and height of the aircraft at different times. The track taken by the aircraft, while circling the dropping zones, has been omitted. Rain echoes appeared on the radar screen in the area of the first drop at 14.03 hr., that is, 18 min. after the release of 'dry ice'. In the second dropping zone, rain echoes were first sighted at 14.12 hr., or 16 min. after the release. It persisted for the rest of the afternoon. No other rain was observed within 100 miles of the aircraft.

Visual observation above the clouds showed a spectacular growth of the second infected cloud. Figs. 3 and 4 give its aspect 9 min. and 13 min. after the dropping. Later, a narrow towering anvil formed (Figs. 5 and 6). Another smaller tower was seen approximately in the direction where the first drop had been made. These were the only two clouds which rose above the general level of the other tops. It is estimated that the bigger one reached a height of perhaps 40,000 ft. The line of frontal clouds, which can be seen along the horizon on some of the photographs, was about 180 miles to the south.

The remarkable rise of the infected cloud may have been due to the liberated heat of fusion. The atmosphere above 23,000 ft. was presumably unstable for changes involving the transformation from vapour to ice (saturated adiabatic relative to ice), although it was stable with regard to condensation processes (saturated adiabatic relative to water). We do not know how frequently such atmospheric conditions occur.

It is emphasized that the meteorological conditions chosen were those which we believed to be most favourable. Before practical application of the results is possible, it will be necessary to establish the minimum conditions and to find out how often they are likely to occur. The phenomenon is related to the temperature distribution, the available amount

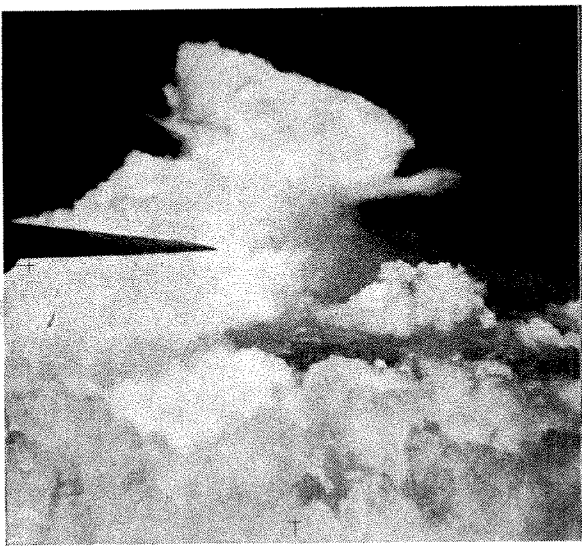

Fig. 5. THE SMALL ANVIL WHICH FORMED AFTER ABOUT TWENTY MINUTES

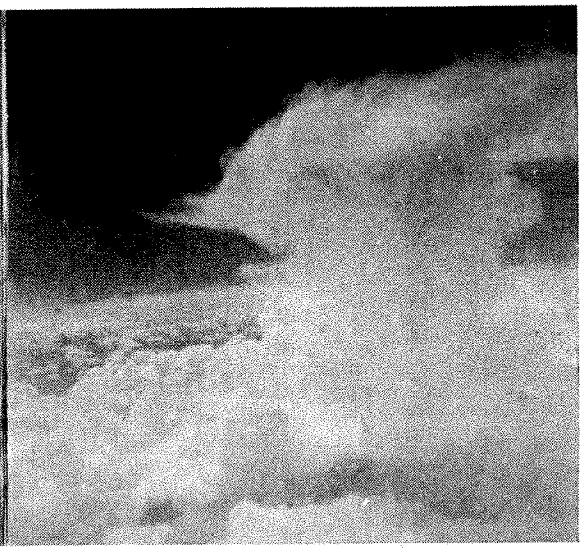

Fig. 6. THE FULLY DEVELOPED ANVIL

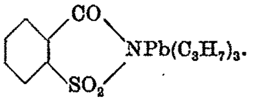
tion. Its solubility in alcohol was high (65 gm. dissolved in 100 c.c. of cold alcohol). The compound could be recovered unchanged from the alcoholic solution after six days.

A large variety of compounds of the type $RSO_2NR'PbR_3''$ were then prepared[9,10], where, for example, $R = CH_3$, C_6H_5, p-$NH_2C_6H_5$, and $R' = H$, C_6H_5, p-ClC_6H_4, p-BrC_6H_4, and $R'' = C_2H_5$, n-C_3H_7, etc. They were without exception good sternutators, with tri-n-propyl lead methane sulphonamide as the most potent, being extremely unpleasant at a concentration of 1 in 25,000,000. It possessed a further advantage on account of its relatively low molecular weight.

One of the most interesting compounds of this series was tri-n-propyl lead o-sulphobenzimide[9] (I), which produced intense irritation and caused the



(I)

observers to leave the chamber after 1½ min. exposure. We reported, also, that the compound, even at this dilution, produced a 'sweet taste'.

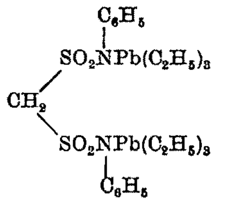
In view of the fact that the sulphonamide grouping on one hand and an unsaturated grouping on the other hand (for example, triethyl lead acrylate and tri-n-propyl lead acrylate) each independently produced an increase in sternutatory effect, it was decided to prepare triethyl lead vinyl sulphonanilide (II):

$$CH_2 = CHSO_2N(C_6H_5).Pb(C_2H_5)_3.$$

(II)

The compound was certainly one of the best sternutators of the triethyl lead series, and at a concentration of 1 in 10^7 gave an atmosphere which was scarcely tolerable. The potency, however, was not so high as might have been anticipated in view of the presence of two 'active' groups[9].

About this time we also prepared and tested methylene bis(triethyl lead sulphonanilide) (III)



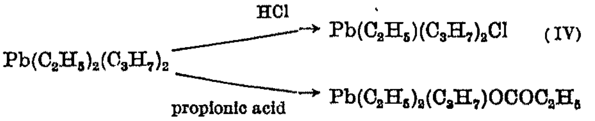
$$CH_2\left[SO_2N(C_6H_5)Pb(C_2H_5)_3\right]_2$$

(III)

Although it was a reasonably good sternutator, its properties were in no way outstanding.

Trialkyl Lead Salts from 'Mixed' Plumbanes

Our work indicated that derivatives of mixed plumbanes possessed rather more pronounced sternutatory properties than did the simple plumbanes. By the reactions outlined in the following scheme, derivatives of diethyl di-n-propyl lead have been made[11,12]. It appeared that a strong acid eliminated one propyl group, whereas a weak acid eliminated one ethyl group.



$$Pb(C_2H_5)_2(C_3H_7)_2 \xrightarrow{HCl} Pb(C_2H_5)(C_3H_7)_2Cl \quad (IV)$$

$$Pb(C_2H_5)_2(C_3H_7)_2 \xrightarrow{\text{propionic acid}} Pb(C_2H_5)_2(C_3H_7)OCOC_2H_5$$

From ethyl di-n-propyl lead chloride (IV), the corresponding ethyl di-n-propyl lead p-toluene sulphonamide was prepared. By the second type of reaction diethyl n-propyl lead propionate and monochloroacetate were prepared.

Aromatic Compounds

Finally, it may be noted that triphenyl lead chloride, triphenyl lead bromide and triphenyl lead iodide were found to be devoid of sternutatory properties[9] at the concentrations employed in our experiments, that is, at concentrations of the order of 1 in 10^6.

Analysis

The preparation of many hundreds of lead organo-lead compounds necessitated the use of a rapid and reliable method of estimating the percentage of lead in such compounds, particularly as carbon and hydrogen analyses were often incorrect. In outline, the method which we employed[3] consisted in digesting the organic compound in concentrated nitric acid, adding ammonia, and then acetic acid. The lead was then precipitated as lead chromate, which was dissolved in dilute hydrochloric acid, and titrated with ferrous ammonium sulphate solution, using ferrous phenanthroline as internal indicator.

Other Organo-metallic Compounds

In addition to the preparation and examination of the lead compounds mentioned above, we also examined organic compounds containing tin, bismuth, thallium and mercury with the view of obtaining a compound having powerful sternutatory properties[9]. It should be emphasized that these metals were in short supply at the time, and only a compound of outstanding potency would have been of any value.

Briefly, the results were as follows. In general, alkyl-tin salts were found to be only feeble sternutators. Triphenyl tin iodide, $(C_6H_5)_3SnI$, however, was found to have sternutatory properties and to be intolerable at a concentration of 1 in 10^6. This was rather unexpected in view of the fact that the corresponding compound in the lead series, namely, triphenyl lead iodide, is devoid of sternutatory properties. This led us to prepare the following triphenyl tin compounds[9,10], none of which had previously been described:

$(C_6H_5)_3SnCH_2COOEt$, $C_6H_5SO_2NHSn(C_6H_5)_3$, and $(C_6H_5)_3Sn.O.COCH_2COEt$.

As sternutators they were useless.

In April 1941 we prepared diphenyl bismuth propionate, bromoacetate, and iodoacetate[11,12]. These were barely tolerable at a concentration of 1 in $2 \cdot 5 \times 10^7$, and unpleasant after-effects were produced. These compounds, however, were difficult to recrystallize. Diphenyl bismuth chloride, bromide and cyanide were prepared according to known methods, and on testing in the chamber proved to be very good sternutators[11,12], and were probably slightly more powerful than *D.A.* (diphenyl chloroarsine).

Also in 1941 we prepared diethyl thallium bromide, diethyl thallium iodide, diethyl thallium acetate and diphenyl thallium acetate according to known methods. Chamber experiments revealed that they were undetected by human observers at concentrations of 1 part in 10^7.

Similarly, the following mercury compounds were devoid of sternutatory properties, but produced a garlic-like odour at a concentration of 1 part in 10^7:

methyl mercuric iodide, methyl mercuric hydroxide, *n*-propyl mercuric chloride and phenyl mercuric iodide.

Summary

A large number of organo-lead compounds have been prepared and tested as potential sternutators at Cambridge. They have been examined at nominal concentrations (for example, 1 in 1,000,000, 1 in 10,000,000 and 1 in 25,000,000) in a 10-cubic metre chamber, the material being dispersed by spraying a solution in alcohol or ether. Four observers (members of the team) entered the chamber for each experiment.

From the results of the experiments, the compounds were placed in various categories with reference to triethyl lead chloride as an arbitrary standard. It has been established in respect of sternutatory power that:

(1) Salts of the trimethyl lead, $(CH_3)_3Pb^+$, series are markedly inferior to those of the triethyl lead, $(C_2H_5)_3Pb^+$, series.

(2) Salts of the tri-*n*-propyl lead series are superior to the corresponding compounds in the triethyl series. In fact, there appears to be a peak of activity in the tri-*n*-propyl series, derivatives of tri-*n*-butyl lead and above exhibiting diminishing activity.

(3) Derivatives of the monovalent ion (for example, $(C_2H_5)_3Pb^+$) are greatly superior to derivatives of the divalent ion (for example, $(C_2H_5)_2Pb^{++}$).

(4) Within a given series, salts of organic acids (for example, the acetate or acrylate) are usually superior to salts of inorganic acids (such as the chloride). The β-chloropropionates and acrylates are particularly potent.

(5) A new series of substituted sulphonamides of the type $RSO_2NR'PbR''_3$ has been synthesized. These are of particular interest. They are easily prepared and are powerful sternutators. As in other series, the tri-*n*-propyl lead derivatives are the most potent, and tri-*n*-propyl lead methane sulphonamide is only slightly less potent than the best arsenicals.

We are indebted to the Chief Scientist, Ministry of Supply, for permission to publish the above. We are grateful to Mr. Davidson Pratt for the interest that he has shown in the work, and also to the Chemical Defence Research Departments, Ministry of Supply, in London and at Porton.

The following took part in these investigations at Cambridge.

SOCIAL MEDICINE AND SOCIAL PATHOLOGY

By Dr. IAGO GALDSTON
New York Academy of Medicine

THE centenary celebration of the New York Academy of Medicine was initiated with a dinner-meeting at the Waldorf-Astoria Hotel on March 6, 1947. Twelve hundred fellows and friends of the Academy gathered in the main ballroom of the hotel and, after dinner, listened to the addresses of the president of the Academy, Dr. George Baehr, and of the guest of honour and principal speaker, Prof. John A. Ryle, professor of social medicine in the University of Oxford.

Dr. Baehr, in his presidential discourse, reviewed the history of the Academy and outlined its anticipated developments in the near future. Prof. Ryle, in his address, discussed the meaning and significance of social medicine and social pathology. Prof. Ryle's address was particularly pertinent in the light of the four-year study which has been conducted by the Academy's Committee on Medicine and the Changing Order. The report of this Committee is to be published shortly.

There is a fairly widespread appreciation in the United States that a substantial number of those items in medical care about which there has been so much discussion (labelled here as "socialized medicine") must and will find a solution in the application of the philosophy and techniques advanced under the head of social medicine.

Prof. Ryle drew upon his thirty years of clinical experience in medicine to bring into prominence the deficiencies in the current teaching and practice of remedial medicine. "I have watched," Prof. Ryle said, "disease in the ward being studied more and more thoroughly—if not always more thoughtfully—through the higher power of the microscope; man in disease being investigated by more and more elaborate techniques and, on the whole, more and more mechanically. Man, as a person and a member of a family and of much larger social groups, with his health and sickness intimately bound up with the conditions of his life and work—in the home, the mine, the factory, the shop, the official on the land—and with his economic opportunity, has been inadequately considered in this period by the clinical teacher and hospital research worker.

"The morbid 'material' of the hospital ward consists very largely—if we exclude the emergencies—of end-result conditions for which, as a rule, only a limited amount of relief repays the long stay, the patient investigation and the anxious expectancy of the sick man or woman.

"With etiology—the first essential for prevention—and with prevention itself the majority of physicians and surgeons have curiously little concern. Nor have they at present the opportunity, nor yet the appropriate types of training or assistance, requisite for the study of etiology or prevention. Their material is mainly selected by four factors: the gravity, the difficulty or the rarity of their cases, or their suitability otherwise for admission to a hospital. Some of the most common diseases, the less lethal diseases and the beginnings of disease are even considered as providing 'poor teacher material'. Health and sickness in the population and their possible correlations with significant and measurable social or occupational influences are outside their province."

Prof. Ryle then cited in illustration a number of diseases, including gastric and duodenal ulcers, which it is not likely that we will master "until we study the victims of the disease at first hand and in relation to their work, their total occupational experience, their communities, their food, their habits and anxieties, and their innate predispositions".

These procedures involve the development of the science of 'social pathology' and 'hygiology', for "the study of the ultimate causes of disease—without which the specific factors can never find their opportunity—goes hand in hand with the study of the causes of health, and how much we have still to learn of the meaning and measurement of health".

Prof. Ryle further defined social pathology as "the medicine and pathology of families, groups, societies or larger populations. Just as human pathology is the related science of clinical medicine—so may social pathology be viewed as the related science of social medicine. Social medicine embraces, on the one hand, the whole of the activities of the public health administration and of the remedial and allied social services, and, on the other, the special disciplines necessary for the advancement of knowledge relating to sickness and health in the community".

Prof. Ryle emphasized the pertinence of his plea, quoting Julian Huxley, who has described current events as a "transition now in progress from the age of 'economic man' to the age of 'social man'. Our profession which is so particularly concerned with man and his welfare," said Prof. Ryle, "must assist this transition with all the scientific and humanist wisdom at its command. Hitherto, our science, like our practice, has evolved along individualist lines. Whatever the several countries may do with regard to the modification of their systems of practice and of service, it seems to me that the scientific study of health and disease in man—the most complex of all social animals—must henceforward concern itself to an ever-increasing degree with the interactions and correlations of disease and health with changing social circumstances. Socially, industrially, politically, we are creating a new age. With it, inevitably, we alter the whole character and distribution of diseases and set ourselves new problems for solution in the fields of medical science, practice and administration."

Prof. Ryle's thesis fitted in very appropriately with the general spirit of the centennial celebration of the New York Academy of Medicine and served as a splendid introduction to the 'Institutes' that have been planned as a part of the centenary celebration; notably the Institutes on Social Medicine, Public Health, and Medical Education. He took part in the Institute on Social Medicine during March 19, 20 and 21, the sessions of which were devoted to the discussion of the following topics: The Changing Concepts of the Relation of Medicine to Society; Social Medicine—Its Differentiation From and Relation to Clinical and Preventive Medicine; Epidemiology in Social Medicine; The Place of Nutrition in Social Medicine; Social Psychiatry and Social Medicine; Social Applications of Psychiatry. The Institute ended with a dinner meeting on March 21, at which Lord Horder, consulting physician to St. Bartholomew's Hospital, London, delivered an address on "Social Medicine: The Appeal of the Common Man".

OBITUARIES

Prof. Pierre Janet

PIERRE JANET, who died in Paris on February 24 at the age of eighty-seven, played a notable part in the development of clinical psychology. He took a degree in philosophy in 1882, and some of his best work was done before taking his degree in medicine eleven years later. He held various academic posts before becoming a professor at the Sorbonne, and was for a time in charge of the psychological laboratory attached to the Sâlpetrière Clinic. It is not easy to trace his personal relationship with Charcot at that period, and their fundamental attitudes were very different. Thus, in his account of the controversy (c. 1886) when Bernheim showed that Charcot's phenomena of hysteria and hypnotism were artefacts, "the results of unskilled suggestion and involuntary training", he wrote ("Principles of Psychotherapy", trans., London, 1925; p. 30): "The victory of the animists was not well received, at least in the scientific world. They acknowledged it but deplored it. The doctrine of Charcot that it defeated was clear, definite, and easy to study; it seemed to bring animal magnetism within the limits of physiology, and that looked like scientific progress."

In 1889 Janet wrote "L'Automatisme Psychologique", in which his conception of dissociation of consciousness subsumes under one formula such apparently disparate manifestations as water-divining, mediumism, the bodily symptoms of hysteria, amnesias, fugues and somnambulisms. In view of the persisting popular belief in the dowser's rod it may be noted that, after describing its use in the pursuit of criminals and the finding of buried treasure, he wrote: "Il est probable que, dans quelques campagnes, subsiste encore la croyance aux révélations de la baguette divinatoire". As a description of what may be supposed to happen in the superficial layers of the mind the theory of dissociation is not incompatible with psychoanalysis, which Janet, however, was not able to accept. In "Les Obsessions et la Psychasthénie", written jointly with F. Raymond in 1903, scarcely any of the bizarre symptoms of these conditions escape recognition. Many are described for the first time, and the writers were a generation ahead in many observations, such as the recognition of writers' cramp as a psychogenic disorder. It is a pity that Janet's word 'psychasthenia' has fallen into disuse, for it avoids the metaphysical assumptions involved in the use of such words as 'neurasthenia' or 'neurosis' to denote pathological mental states.

Much of Janet's writing has been translated and published in Britain and in America. Running through all is an emphasis upon the history of psychopathology, which helps in the understanding of some fundamental differences of opinion that still exist. It must be admitted that his work received little recognition from the medical profession in France, for the spirit of the times was not yet in accord with his psychological approach. In the First World War the French were quick to recognize the importance of psychoneuroses in soldiers; but in their plentiful literature on the subject there seems to be no reference to his teachings. In Great Britain, however, the application of his work on amnesia threw light upon these conditions, and in the Second World War the use of pentothal in the revival of war memories was a tribute to his observation that "ether, chloroform, and ethyl chloride have been used to bring about hypnotic sleep with some interesting results" (*loc. cit.*, p. 134).

Outside the medical world, however, Janet received full recognition, becoming president of the Academie des Sciences Morales et Politiques, while to many Parisians he was affectionately known as 'Papa Janet'. Last autumn, in spite of his years, he travelled to Zurich and delighted a psychological congress with the charm and erudition he showed in an extempore address. His work is now rather overshadowed by the developments of psychoanalysis, but he stands out as the pioneer who, almost single-handed, brought psychology into practical alliance with medicine.

MILLAIS CULPIN

Dr. A. H. Jay

THE tragic death of Dr. A. H. Jay on February 27 at the age of forty removes one of the most colourful characters from the ranks of X-ray workers in Great Britain. At conferences and discussions one could always be sure that Dr. Jay would present a novel aspect of whatever problems were being aired, and he presented it with a vigour that was characteristic of the man. His pronounced north country accent and his use of personal reminiscences gave his lectures a spice and flavour out of the ordinary.

Those who knew him on more intimate occasions knew also that his originality was not reserved for the lecture room; it manifested itself in many different ways, in research and in committee meetings. As a member of the committee of the X-ray Analysis Group of the Institute of Physics, Jay was a staunch advocate of individuality, and strongly opposed those of us who wished to introduce more standardization into X-ray matters; he had designed and built most of his own X-ray equipment, and he did not see why the coming generation of research workers should not do the same. What he did not realize was that so few were possessed of his energy and initiative, his ability to overcome obstacles. As an example, his high-temperature camera might be cited. Jay designed this camera at Manchester and did much useful work with it; yet, after he left, nobody produced any results with it. The reason for this was obvious: there were so many points in it that had to be attended to at once that only Jay could manage to look after them all!

Jay's qualities were particularly well suited to the type of research work he undertook. His work with Bradley on superlattice formation in the iron–aluminium system is accepted as a model of completeness, and has been the basis of much theoretical investigation. It involved a quantity of measurement that would have daunted a lesser man, but work seemed to give Jay an appetite for more. This quality stood him in good stead in his work for industry, which involved the taking of large numbers of X-ray photographs of refractories. The interpretation of these photographs and the analysis of the results obtained from them enabled him to make many important fundamental contributions to the study of these materials, and it is probably true to say that the main importance of these contributions has yet to be seen.

It is sad to think that he has not lived to enjoy the pleasure of seeing his results applied. Britain can ill afford the loss of men of Jay's type in the present sombre conditions.

H. LIPSON

WE regret to announce the following deaths:

Mr. C. W. Hobley, C.M.G., secretary during 1923–36 of the Society for the Preservation of the Fauna of the Empire, on March 31, aged seventy-nine.

Dr. Willard L. Valentine, editor of *Science* since January 1946, formerly professor of psychology in Northwestern University, on April 5, aged forty-two.

Henri Vallée, *Correspondant* for the Section of Rural Economy of the Paris Academy of Sciences, on March 12.

NEWS and VIEWS

Bacteriology and Immunology in the University of London: Prof. E. T. C. Spooner

DR. E. T. C. SPOONER, who has been appointed to the University of London chair of bacteriology and immunology tenable at the London School of Hygiene and Tropical Medicine, went to Epsom College and to Clare College, Cambridge, where he obtained first classes in both parts 1 and 2 of the Natural Sciences Tripos. After the completion of clinical study at St. Bartholomew's Hospital, he was house-physician to the late Sir Walter Langdon-Brown; he was elected to a Commonwealth fellowship and worked for two years with Prof. Hans Zinsser in the Department of Bacteriology of Harvard University. On his return from America he was elected to a fellowship at Clare College, and a University demonstratorship in the Department of Pathology at Cambridge. He was later elected to a University lectureship and took charge of the teaching in bacteriology for both Part 1 and Part 2 of the Natural Sciences Tripos.

On the outbreak of war in 1939, Spooner became a member of a group of workers at St. Bartholomew's Hospital, which had been 'evacuated' to St. Albans, who were engaged in the study and prevention of the spread of streptococcal infection in surgical wards. Afterwards Dr. Spooner was appointed by the Medical Research Council as the bacteriologist member of a group of medical men who were sent to the Middle East to report on the hospitals and laboratories in North Africa, Egypt and Palestine. On his return to England, Dr. Spooner was for a time in charge of the E.P.H.L.S. laboratory at Cambridge. At the end of the War, Dr. Spooner resumed his work as a University lecturer; in 1944 he was appointed senior tutor of Clare College. Dr. Spooner has published work on the spread of infective disease, especially streptococcal infection, and for his work in this field was awarded the Horton Smith Prize at Cambridge. His chief interest is in the filterable viruses and in virus-produced disease.

Awards of the Valdemar Poulsen Gold Medal

THE Valdemar Poulsen Gold Medal was instituted by the Academy of Technical Sciences in Copenhagen on the occasion of Valdemar Poulsen's seventieth birthday on November 23, 1939, and the first award was made on that date to Dr. Poulsen himself. Owing to the War, it was not possible to make further awards until 1946, when medals were awarded to Dr. E. F. W. Alexanderson and to Sir Robert Watson-Watt.

Dr. E. F. W. Alexanderson was awarded a Valdemar Poulsen Gold Medal for outstanding contributions to radio-technics, and particularly for the development of a radio-frequency alternator of high power and other system components important in the early progress of radio communication; Dr. Alexanderson was born in Sweden, but his whole work with radio-technics has been done in the United States, where he is a chief engineer of the General Electric Co. at Schenectady.

Sir Robert Watson-Watt was awarded a Valdemar Poulsen Gold Medal for outstanding contributions to the development of radio and particularly for his leading scientific part in the invention and development of the use of radiolocation.

New Chairmen of Research Boards

THE Lord President of the Council has made the following appointments to chairmanships of research boards of the Department of Scientific and Industrial Research from April 1, 1947: Sir Edward Salisbury, director of the Royal Botanic Gardens, Kew, to be chairman of the Forest Products Research Board in succession to Prof. V. H. Blackman; Engineer Vice-Admiral Sir Harold Brown, recently senior supply officer, Ministry of Supply, formerly engineer-in-chief of the Fleet and, during the War, controller general of munitions production, to be chairman of the Fuel Research Board in succession to Sir Harold Hartley; Sir Stanley Angwin, chairman of Cable and Wireless, Ltd., formerly engineer-in-chief of the General Post Office, to be chairman of the Radio Research Board in succession to Lieut.-Colonel Sir George Lee.

A New Form of Camera

MR. EDWIN H. LAND, president and director of research of the Polaroid Corporation, demonstrated recently before the Optical Society of America a camera which produces a dry positive on paper 60 sec. after releasing the camera shutter. The camera contains a roll of film of conventional type, except that the support is opaque, and the exposure is made in the usual way. The camera also contains a roll of specially prepared paper which is not sensitive to light. The paper support is also opaque, and has attached, at intervals equal to the length of the picture, capsules containing a viscous solution of the processing materials. This solution includes hydroquinone and 'hypo' and is released when the capsule is burst on passage of the film and paper between pressure rollers. This takes place after exposure, and the solution is spread as a thin layer between the film and paper, where the following action is said to take place. The hydroquinone rapidly reduces the silver halide in the film in those regions where light action has taken place, thus immobilizing the silver in these regions. In the unexposed regions the 'hypo' takes the silver halide into solution, and diffusion and reduction take place, with the result that silver is deposited in the prepared surface of the paper, producing an image in silver. Since most silver is deposited in the paper in those regions where the least exposure occurs in the camera, the paper image is a positive. The film and paper are pulled apart when the action is complete, yielding a paper 'print' which has a slightly damp surface. The film-paper sandwich passes out of the camera immediately after passing the pressure rollers. The purpose of the opaque supports is to protect the film from further light action while the 'processing' is taking place. In some variants of the system further prints can be obtained from the 'negative', but in general it appears necessary to rephotograph the original to obtain further copies.

Historia Naturalis

IN September 1944, a small group of biologists met in Rome to consider means of promoting the interests of their science, and by December of the same year their suggestions had received sufficient support to justify the formation of a society of naturalists, Unione Italiana Naturalisti. By 1946, the society was strong enough to issue its own journal. This publication, *Historia Naturalis*, is about the same size as *Nature*, and each part so far published consists of 24 pages, exclusive of the cover. It is illustrated with line and half-tone text figures and is quite well printed. It appears three times a year—in March, June and September—and the issues of the first year are now to hand.

The object of the journal is not merely to record the meetings and activities of the society, which are many—indeed these only occupy a page or two—but to emphasize the fundamental unity of the biological sciences, interpreting these in a wide sense. It appeals not only to the professional specialist but also to the intelligent amateur. The major portion of each issue is therefore devoted to original studies and researches, to reports of conferences and symposia, to reviews and essay reviews covering diverse aspects of natural history. The original contributions have included, among others, general and vertebrate palæontology, geology (tectonics), evolutionary problems, animal populations and experiments on Coleoptera. We should like to congratulate our colleagues on their courage in making a start in this field when general conditions were far from encouraging, and welcome the new journal, which undoubtedly fills a need. If the publication fulfils the promise of its first year—and there is no apparent reason why it should not—it is assured of a permanent place in scientific literature. The annual subscription to *Historia Naturalis* is 150 lire, to be sent to Domenico Rossi, via Tomacelli, 132, Rome.

Engineering Degree Courses for Ex-Servicemen

MANY who were studying engineering before being called up for national service have been unable to complete degree courses, and although they have become competent engineers, their future career would benefit greatly if they were able to obtain a degree. Mr. O. S. Puckle, of R.F. Equipment Ltd., Langley Park, near Slough, Bucks, believes that suitable courses of study at a number of technical colleges throughout Great Britain, either in the form of a full day on Saturday or a half-day on Saturday and, say, one, or at most two, evenings per week, could be devised to meet this need. He therefore invites engineers or physicists who are interested in such a proposal to communicate with him. Should the number of replies prove to be sufficient, he proposes to communicate with the Ministry of Education in order to ascertain whether something can be done to meet the situation. He has in mind two types of course, covering two or three years and leading to final B.Sc. or B.Sc.(Eng.), depending on whether the intermediate examination has been passed. Replies, stating the nearest technical college which could be attended, should be sent to Mr. Puckle as early as possible.

World Power Conference on Fuel Economy

A PRELIMINARY programme has been issued of a sectional meeting of the World Power Conference to be held at The Hague during September 2–9, 1947, when the subject of discussion will be "Fuel Economy". The proceedings will be divided into three sections dealing with production, distribution and utilization respectively. Copies of national reports on fuel economy prepared at the request of the central office of the World Power Conference and also of all printed papers prepared for the meeting will be supplied to members of the Conference; all sessions will be devoted to oral discussion. Papers can only be submitted through national committees; the address of the British National Committee is 201–2 Grand Buildings, Trafalgar Square, London, W.C.2, to which intending members resident in Great Britain should apply for particulars. The address of the secretariat for the meeting is Vereeniging voor Congressen op Electrotechnisch en Aanverwant Gebied, 210 Utrechtscheweg, Arnhem, Netherlands.

X-Ray Analysis Conference

The 1947 Conference of the X-Ray Analysis Group of the Institute of Physics will be held at the Royal Institution, Albemarle Street, London, during April 22–23. The first day will be devoted to discussion of the training of X-ray crystallographers for science and for industry; the second will be devoted to new techniques and results. Mr. H. P. Rooksby, of the Research Laboratories, General Electric Co. Ltd., Wembley, will give an evening lecture on the technique of X-ray powder photography on April 22. Short papers only are being given, so as to leave time for informal discussions. The Conference is open to all interested in the subject. Further particulars can be obtained from the honorary secretary of the Group, Dr. F. A. Bannister, British Museum (Natural History), London, S.W.7.

Conference on Applications of Radioactive Tracer Elements

A CONFERENCE is being arranged by the Manchester and District Branch of the Institute of Physics on "Applications of Radioactive Tracer Elements in Physics Research and Industry" during July 10–12 in the Physics Department of the University of Manchester. The opening papers will be given by Dr. J. D. Cockcroft, Prof. F. Paneth and Mr. D. H. Wilkinson. The conference will be open to anyone interested, without charge, but admission will be by ticket only. Further particulars will be issued in due course by the Conference Secretary, W. J. Meredith, Christie Hospital and Holt Radium Institute, Wilmslow Road, Manchester 20.

University of Durham: Appointments

THE following appointments have been made in the University of Durham: Martin Jones, to be professor of agricultural botany at King's College, Newcastle; Ewen M'Ewen, to be professor of engineering in the Faculty of Agriculture at King's College, Newcastle; Alexander Kennedy, to be professor of psychological medicine at King's College, Newcastle; Leonard Slater, to be reader in geography in the Durham Colleges.

Arthur Stanley Eddington Memorial Lectureship

LAST year an appeal was launched to provide for the founding of an Arthur Stanley Eddington Memorial Lectureship to commemorate Eddington's life and work, by providing for lectures on some aspect of contemporary scientific thought considered in its bearing on the philosophy of religion, or on ethics, and to be delivered periodically in Cambridge, or elsewhere, and to be published. The Foundation Trust Deed has now been completed, and the following four trustees have been appointed: Prof. Sydney Chapman, representing the Royal Society; Prof. C. D. Broad, representing Trinity College, Cambridge; Dr. Kathleen Lonsdale and Dr. W. H. Thorpe, representing the Society of Friends. Mr. Howard Diamond, 45 St. Barnabas Road, Cambridge, is honorary treasurer and secretary of the trustees. The Fund is still open, and approximately £1,000 is now needed for its completion. It is hoped that the first lecture on the Foundation will take place towards the end of the present year.

The Boron-Trifluoride Catalysed Reaction of Di-isobutene

Dr. Alwyn G. Evans and M. A. Weinberger write: "In our recent communication on this subject [*Nature*, March 29, p. 437], it is stated that the addition of acetone vapour, purified by distillation *in vacuo* over freshly distilled sodium, to a non-reacting mixture of di-isobutene vapour and boron trifluoride initiates the fast reaction of di-isobutene. In our corrected proof of this letter [received too late for changes to be made. Editors] we deleted this statement on the grounds that since traces of water are so effective in initiating this reaction, we do not as yet wish to claim that completely pure acetone itself is effective in this way."

Announcements

THE James Watt International Medal for 1947 of the Institution of Mechanical Engineers will be presented to Prof. S. Timoshenko, recently professor of engineering at Stanford University, California, on April 25; he will speak on "Stress Concentration and Fatigue Failures".

MR. F. BRUNDRETT, of the Royal Naval Scientific Service, has been appointed chief of the Service in succession to Sir Charles Wright, who retires on April 30.

BY arrangement between the University of Sheffield and the Council of the Iron and Steel Institute, the second Hatfield Memorial Lecture will be given by Dr. C. Sykes, of the Brown–Firth Research Laboratories, Sheffield, in the Institution of Civil Engineers, London, on May 14 at 8.30 p.m., on the occasion of the annual general meeting of the Iron and Steel Institute, and will be entitled "Steels for Use at Elevated Temperatures".

DR. DOUGLAS GUTHRIE is delivering a course of lectures in the University of Edinburgh on the history of medicine, beginning on April 17. As part of the course, guest lectures will be given by Sir Arthur MacNalty on the evolution of preventive medicine in Britain on May 16, and by Sir Henry Bashford on Hans Sloane on May 23.

ERRATUM. In the communication "Spiral Cracks in Glass Tubes" by Dr. L. Norzi, published in *Nature* of March 1, p. 306, paragraph 5, line 2, for "$tg2\varphi = 2C|(B - A)|$" read "$tg2\varphi = 2C/|(B - A)|$".

Plasma Cellular Reaction and its Relation to the Formation of Antibodies *in vitro*

DURING secondary response, elicited in sensitized rabbits by means of intravenous injections of the homologous antigen, the number of plasma cells in the spleen increased considerably, simultaneously with the formation of antibodies[1]. The cellular reaction was localized almost exclusively to the red pulp, especially after the injection of living *Salmonella typhi* (about 500 millions/kgm.). The spleen was investigated by means of biopsies at intervals during antibody formation; differential counts of imprints were made and histological sections were examined. The stain used was methyl green pyronine (Unna–Pappenheim). In the earliest stages of the reaction, in the first phase of antibody formation, large reticulum cells of characteristic appearance (called transitional cells) presented themselves. One or two days later, immature plasma cells appeared at the places where transitional cells were previously found, and after a further few days mature plasma cells were seen in increasing numbers. There were numerous transitions between the different stages of development. No plasma cells were usually seen in the lymph follicles.

* Lymph. gland. axill., regional to the subcutaneous agar focus containing antigen, through which the rabbit was sensitized.

Antibody formation in vitro. Small pieces of spleen tissue, partly from the red pulp, partly from the lymph follicles, were excised in different phases of antibody formation, and their capacity for forming antibodies *in vitro* was investigated. In each tube, containing 300 mgm. of fluid, one or two pieces were cultured. Their weight (wet) was about 0·2 mgm. The culture fluid consisted of normal rabbit serum (3 parts), tyrode solution (2 parts) and isotonic sodium bicarbonate (1 part). A gas mixture, consisting of 80 per cent oxygen, 4·5 per cent carbon dioxide and the remainder nitrogen, was passed into the tubes[2]. The tubes were incubated at 37° for 5–12 hours. The capacity for antibody formation *in vitro* of the red pulp rich in plasma cells proved to be considerably superior to that of the lymph follicles (see Table 1). By serial investigations on the same animal, it was found that the tissue pieces were most active in forming antibodies when the immature plasma cells predominated. The transition from immature to mature cell coincided with a decline in the capacity to form antibodies *in vitro*. Pieces of the same size were excised from other organs rich in R.E.S. Their capacity for antibody formation *in vitro* was investigated and proved to be very much inferior to that of the red pulp of the spleen (see Table 2). Experiments were also made to trace the antigen (living *Salm. typhi*) after intravenous injection. The greatest number of bacteria was found in spleen and liver, less in bone-marrow, and very few bacteria could be demonstrated in lymph glands and thymus. In the spleen the bacteria were found in large numbers in the red pulp, and only small numbers in the follicles.

It is concluded that plasma cells appear in connexion with great antigen stimulation. The antigen incites a conversion and an intensification of the protein production in the reticulo-endothelial cell. From the functional point of view, development culminates in the formation of the immature plasma cell. The further differentiation of the cell, when mature plasma cells appear, marks the transition to a less active state, and the mature plasma cell then becomes the final link in a chain of development, a cell which has already passed its greatest functional activity.

Phenyl-thio-carbonyl Chloride as a Group-protecting Agent

THE use of the carbobenzoxy reagent for protection of amino-groups in the course of peptide synthesis has, in spite of its obvious advantages, some limitations. In some cases, hydrogenolysis of the benzyl group is complicated by simultaneous hydrogenation of other groups present, and also carbobenzoxy compounds are sometimes difficult to crystallize; for example, *N*-carbobenzoxy-glycyl-cysteine ethyl ester. The use of another protecting unit easily removed by hydrolysis in combination with the carbobenzoxy method would considerably extend the use of the latter.

Phenyl-thio-carbonyl chloride, $C_6H_5S-COCl$, as prepared by Rivier[1], would appear to be of use in this respect. The corresponding amide and phenylamide were reported by Rivier to be stable in dilute acids and easily hydrolysed by alkalis. The extension of the method to other amides and to the amino-acid series has now been developed. Direct Schotten–Baumann acylation in aqueous alkali solution was not very successful, but the reaction of one mole of phenyl-thio-carbonyl chloride with 2 moles of amino-acid ester in ether or ethyl acetate proceeds easily at room temperature, one mole of amino-acid ester hydrochloride being liberated. After washing with dilute hydrochloric acid, the phenyl-thio-carbonyl amino-acid esters are easily isolated. Among the compounds prepared are phenyl-thio-carbonyl-glycine ethyl ester, m.p. 104°, and bis-(phenyl-thio-carbonyl)-cystine dimethyl ester, m.p. 108°.

The acylamino-acid esters thus prepared are easily de-esterified by heating for ten minutes in a mixture of concentrated hydrochloric acid and glacial acetic acid (1 : 1), the phenyl-thio-carbonyl group being remarkably stable in acids. The free acylamino-acids separate on dilution with 2 moles of water (for example, phenyl-thio-carbonyl-glycine, m.p. 155°), and can be converted to the corresponding chlorides by the action of phosphorus pentachloride in ether. The chlorides (for example, phenyl-thio-carbonyl-glycine chloride, m.p. 87°) crystallize readily and are rather stable. They react in ether or chloroform solution with free amino-acid esters to form peptide esters: phenyl-thio-carbonyl-glycine-glycine ethyl ester, m.p. 127°, phenyl-thio-carbonyl-glycine-*dl*-alanine methyl ester, m.p. 116°, phenyl-thio-carbonyl-glycine cysteine ethyl ester, m.p. 114°. The latter crystallizes readily, unlike the corresponding carbobenzoxy compound. In general, the melting points of the phenyl-thio-carbonyl derivatives lie about 50° above those of the carbobenzoxy compound.

The removal of the phenyl-thio-carbonyl-group is easily carried out by heating for five minutes with a solution of lead acetate in 70 per cent ethanol or by treating in the cold with 0·1 *N* alkali in the presence of lead hydroxide or lead carbonate, yellow lead phenylmercaptide being precipitated. In alkali, phenyl-thio-carbonyl-amino-acids are decomposed in 10–30 sec., the corresponding esters reacting similarly in 5–10 min.

This observation, together with the fact that PhS—CO—O— and PhS—CO—S compounds could be similarly prepared and split, provides a basis for an extension of peptide synthesis. Compounds of the type PhS—CO—O*R* can be prepared by heating the appropriate alcohol with phenyl-thio-carbonyl chloride either alone or with alkali (10 per cent). The alcohol can also be employed in the form of alkoxide. Phenols and SH-compounds react in the same way. The use of phenyl-thio-carbonyl chloride is capable of a number of variations and should find useful applications in other fields.

Full details of this work in connexion with peptide synthesis will be published elsewhere.

Use of Seeds in the Insect Transmission of Some Plant Viruses

THE methods previously adopted for the insect transmission of the viruses causing swollen-shoot disease of cacao (*Theobroma cacao* L.) employed seedlings usually between six and twelve months old. An improved technique utilizes the seed as a test plant and a watch-glass or specimen tube as a cage, a method which might be applicable to experiments with viruses of other plants with exalbuminous seeds.

The cacao bean is taken from the ripe pod, the testa removed, and one cotyledon dissected away to expose the convoluted surface of the other. Insects which have fed on an infected plant for the required time are transferred with a brush to the bean, placed in a solid or 'block' watch-glass. Humidity can be maintained by a square of damp filter paper under the cover of the watch-glass, and after the desired feeding time, the insects are killed with nicotine solution. The beans are then planted in sterilized sand in an insect-proof house. Germination is not affected, and symptoms usually appear in the first or second pair of foliage leaves, occasionally in the third. The vectors used successfully in these experiments are the mealy-bugs, *Pseudococcus citri* Risso, *Ps. njalensis* Laing, and *Ferrisia virgata* Ckll., which feed readily on the beans not only of cacao but also of *Cola* spp., and of *Phaseolus vulgaris*.

The use of beans in small containers has numerous advantages over that of larger plants in pots. The movement of the vectors is controlled, and feeding periods can be observed conveniently with a microscope. Complete exclusion of other insects is ensured without the necessity for cages, and a large number of test plants can be accommodated in a small space in the laboratory. Unless the virus under investigation is seed-transmitted, when care would be taken to ensure an uninfected source of seed, any chance of prior infection of the test plants is eliminated, together with the difficulty of maintaining a constant source of virus-free plants of the correct size and condition for vector experiments. Not the least important advantage of the method as applied to cacao is a shortening of the mean period between the time of infection and of the development of symptoms, and a reduction in its variation between plants. In experiments using large plants, the interval between inoculation and the appearance of symptoms depends on the periodicity of growth-flushes, which differs greatly with season and also between plants, resulting in latent periods varying between three weeks and four months. When seed is used, symptoms are usually visible in the leaves about three weeks after the beans were infested.

The method can be modified for testing suspected vectors found in natural outbreaks of virus diseases far distant from the laboratory. Peeled cacao beans are planted in damp sterilized sand in specimen tubes of suitable size, with the mouth sealed with muslin held by a rubber band. Germination commences at once, and a seedling can be kept in each tube for about two weeks prior to transplanting. Suspected vectors found on infected plants are transferred to the cotyledons and allowed to feed until the return to the laboratory, where they are removed and the seedling planted. In this way virus transmissions were carried out in outbreaks of swollen-shoot disease in the Ivory Coast, and the infected plants established in the Gold Coast after a tour of 1,400 miles lasting seventeen days.

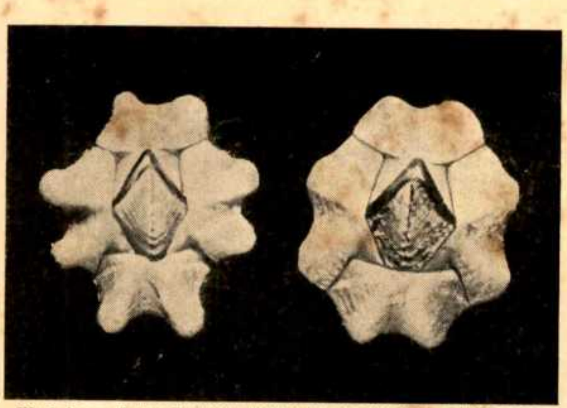
Establishment of an Immigrant Barnacle in British Coastal Waters

As part of the programme of anti-fouling investigations being carried out by the Marine Corrosion Sub-Committee of the British Iron and Steel Research Association, data have been collected on the nature of fouling organisms and their seasonal variations of settlement and growth at a number of stations around the British coasts. A full account of this work and of work on the fouling of ship bottoms will be published at a later date, but it seems desirable to record the establishment in British waters of an austral barnacle, which appears to have arrived as a component of ship-fouling.

The examination of small, unpainted 'Bakelite' panels immersed for successive monthly periods at constant depths of 2 ft. and 4 ft. from the Admiralty Raft inside the mouth of Chichester Harbour, West Sussex, has shown that heavy settlements of acorn barnacles characterize the fouling settling at this site from mid-March to the end of October. These barnacles have been identified as *Elminius modestus* Darwin, a common estuarine barnacle in southern Australia and New Zealand, and *Balanus improvisus* Darwin, a common estuarine form in British and northern temperate waters. The settlement density and relative numbers of the two species have varied from month to month, but in general the former species has been the more abundant. In July 1945 the average numbers were two hundred *E. modestus* and two *B. improvisus* per square inch of surface area. The alien species has grown well (attaining a carino-rostral diameter of 6 mm. in 40 days during June and July), but less rapidly than *B. improvisus*, which furthermore appears to be a larger species when fully grown.

Darwin[1] gives the distribution of the genus *Elminius* as "southern temperate seas", and of the species *E. modestus* as "New South Wales, Van Diemen's Land, New Zealand"; and Gruvel's brief reference[2] to a new species, *E. cristallinus*, from the Azores appears to be the only published report of the occurrence of the genus in the northern hemisphere. Moore[3], in a recent account of *E. modestus*, describes it as a common estuarine, inter- and sub-tidal form in New Zealand, averaging 5 mm. in diameter, breeding throughout the year and occurring as fouling on harbour vessels and test panels. This species in its native waters appears to occupy the position held by *B. improvisus* in the British fauna. Its appearance is superficially not unlike that of the common British shore barnacles, but a close examination shows that the compartments are reduced to four in number (see photograph) in contrast to six present in the genus *Balanus*.



Elminius modestus DARWIN, TAKEN FROM CHICHESTER HARBOUR, SHOWING THE ARRANGEMENT OF THE FOUR COMPARTMENTS. NATURAL SIZE, 6 MM. CARINO-ROSTRAL DIAMETER

I have been unable to examine the shore of Chichester Harbour for the alien species, but the foregoing data clearly show that *E. modestus* is well established at this site. Two further records of the species, in both cases associated with *B. improvisus*, suggest that this immigrant is also present in other localities on the coast. The species was taken from the hull of the S.S. *Queen Elizabeth* (August 1946) after a long stay at Southampton subsequent to North Atlantic service, and from the hull of the M.V. *Empire Wansbeck* (October 1946), which had been plying between Harwich and the Hook of Holland.

Observations on ship-fouling show that a variety of foreign marine organisms, often fully grown and living, are continually being brought into British waters on ship hulls, and that many of these species are able to survive for long periods while the vessels are in British ports. There is little evidence, however, that alien species have been introduced to the coasts of Great Britain in this way, and probably the low water temperature prevents breeding in most of these species (Orton[4]), a consideration which would not apply to warmer seas. It is of interest to note in this connexion that in 1937 Mr. D. Dilwyn John (personal communication) collected a species of foreign barnacle, probably a variety of *B. amphitrite*, from buoys in the Shoreham Harbour Canal, the water of which was heated to approximately 10° F. higher than the outside channel water (in November of that year) by large discharges of hot sea water.

It seems likely that *E. modestus* has been carried from its native coasts to the south coast of Britain as fouling on a ship, and being a temperate water species, has been able to establish itself. This theory is supported by the occurrence in October 1946 of this species on the hull of the M.V. *Waipawa* at Liverpool, after service in southern Australia and New Zealand. These specimens of *E. modestus*, associated with *B. amphitrite* Darwin and *B. trigonus* Darwin, were living, in good condition, and fully grown (9 mm. carino-rostral diameter), but the gonads were in a very early stage of development. All three species had successfully survived a fast passage at 17 knots for 30 days, via the freshwater lakes of the Panama Canal.

I am grateful to Dr. J. P. Harding, British Museum (Natural History), for confirming the identity of

E. modestus, to Dr. H. G. Stubbings (Admiralty) for supervising the exposure of panels in Chichester Harbour, to the Cunard White Star Line, Ellerman's Wilson Line and Shaw Savill and Albion Line for their assistance, and the Marine Corrosion Sub-Committee for permission to publish this communication.

British Folliculinidæ (Ciliata, Heterotricha)

While examining plates submerged in sea water at Cullercoats, I have come across two species of Folliculinidæ which, to my knowledge, have not been reported so far from Great Britain. They are *Folliculinopsis* (*Folliculina*) *producta* Wright and *Folliculina simplex* Dons. The *Folliculinopsis producta* forms are remarkable for their large size and extreme elongation of the body, the overall length of my specimens ranging from 2,000 μ to 2,600 μ (2·0–2·6 mm.); and a few specimens were as long as 3 mm., a large size indeed for a simple non-colonial protozoon. The biology of these two species has been worked out and is being published elsewhere.

Sixteen well-marked species of Folliculinids are known from the Continent[1,2] and ten species from the United States[3], while only three species have been recorded from Great Britain so far[4,5,6], namely, *Folliculina ampulla* Müller (Plymouth and Port Erin), *Folliculina elegans* Clap. and Lach. (Port Erin), and *Parafolliculina hirundo* Kent (Channel Islands). The present two species from Cullercoats bring the number of British Folliculinidæ to five.

My thanks are due to Prof. A. D. Hobson for helpful suggestions and to Dr. H. O. Bull for assistance in identification.

Entamœba sp. from the Syrian Hamster (*Cricetus auratus*)

During the course of work on experimental infections of *Entamœba histolytica* in rats, it was noticed that rats sometimes developed spontaneous infections with an amœba showing characters differing from those of *E. histolytica*. An examination of hamsters, which were housed in the same room, revealed the presence of a similar amœba. Hitherto there has been no report of an amœba parasitic in the hamster.

All observations were made on fresh material, an also on fixed and stained smears made from hamste used for tests of leishmanicidal drugs.

Amœbic infection was found in fifty hamste (59 per cent) of eighty-five examined; of these, thirt seven harboured only the trophic amœbæ, whi thirteen also had cysts. Pseudopodia consisted ectoplasm, clearly demarcated from the endoplas and in stained specimens presented a homogeneo structure. In a fresh smear the rounded forms ha a diameter of 17–28 μ. The spherical nucleus varie in size between 3·50 and 5·75 μ; it contained a co pact, rather irregularly shaped karyosome whic occupied a very eccentric position, being frequent situated near the nuclear membrane. The periphe chromatin consisted of a layer of fine granules mo or less in contact with one another. The endoplas was vacuolated; food vacuoles contained bacteri plant debris, and other Protozoa, chiefly trichomonad *Sphœrita* was also present in some cases.

The ripe cysts contained eight nuclei, the kary somes of which were usually strongly eccentri Chromatoid bodies, not commonly present, wer elongated with irregular ends. The cysts ranged i size from 12·5 to 22 μ in diameter, with an averag size of 17 μ. No evidence of races of larger or smalle dimensions has yet been obtained.

Experiments were performed to determine whethe the amœbæ from the hamster were infective to rat Suspensions of cæcal contents of infected hamste were administered orally to young rats each receivin 0·25 ml., containing eighteen cysts. The rats wer isolated in cages, special precautions being taken t prevent accidental contamination, and the cæc examined after ten days. Nine of eleven inoculate animals developed amœbic infections, while norma control animals kept under identical conditions a remained free from infection.

The amœbæ from the hamster thus proved to b infective to rats. The morphology of the trophi amœbæ and cysts was unaltered in the second host The amœbæ were found to survive for a time i Dobell and Laidlaw's horse-serum and Ringer eg medium[1], but did not multiply and died after twent four hours.

The amœba was apparently non-pathogeni although two of the experimentally infected rat showed slight diarrhœa. From these observation it would seem that the rats might acquire thei infection from hamsters kept in the laboratory.

Fuller details of this investigation will be publishe elsewhere.

Isotropy in the *J* Striation of Striated Muscl

Frey-Wyssling[1], following Hürthle, explains th isotropy of the *J* striation in muscle as the crossin of micellar structure. C. E. Hall, M. A. Jakus an F. O. Schmitt[2] established by electron micrograph that myofibrils are composed of parallel bundles filaments lying axial with the fibrils both in the and *J* striations. On the basis of their experiment these authors put forward two hypotheses to explai the isotropy: it is caused either by differences in orientation within the filaments in the J striation, or by a component which compensates the positive birefringence of the filaments.

We have carried out investigations on rat muscle. Muscle pieces 1 cm. long and of 2–3 mm. diameter were treated for 20 minutes at 0° with a solution containing 0·6 mol. potassium chloride + 0·04 mol. sodium bicarbonate + 0·01 mol. sodium carbonate + 1·0 per mol. adenosintriphosphate. After this they were treated for another 20 min. with 0·6 mol. potassium iodide solution. In this way the contractile substances (myosin and actin) were extracted[3,4]. Then the pieces of muscle were put into solutions of potassium iodide of successively decreasing concentrations until, by swelling, the muscle pieces regained their original size.

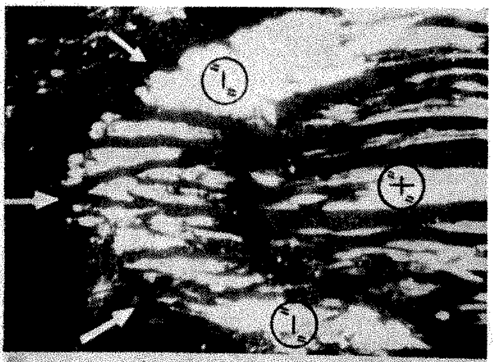

Fig. 1

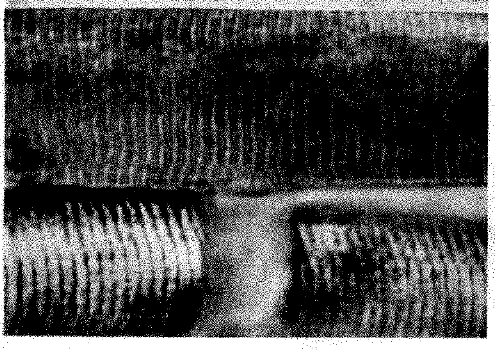

Fig. 2

Fig. 1. A BUNDLE OF MUSCLE FIBRES TREATED WITH WEBER'S SOLUTION AND WITH 0·6 MOL. POTASSIUM IODIDE. THE ARROWS SHOW THE DIRECTION OF PENETRATING SOLUTIONS. PHOTOGRAPHED IN POLARIZED LIGHT USING A GYPSUM PLATE (RED I.) AT + 45°. THE FIBRES MARKED "+" ARE INTACT SHOWING POSITIVE DOUBLE REFRACTION; THE MARGINAL FIBRES MARKED "|" HAVE A NEGATIVE DOUBLE REFRACTION

Fig. 2. (*a*) AN UNTREATED MUSCLE FIBRE IN POLARIZED LIGHT USING GYPSUM PLATE (RED I.) AT + 45°. THE Q STRIATION AND THE Z LINE ARE BLUE (LIGHT IN PHOTOGRAPH); THE J STRIATION IS DARK

(*b*) A MUSCLE FIBRE TREATED WITH WEBER'S SOLUTION + POTASSIUM IODIDE (SIMILAR ADJUSTMENT). THE J STRIATION IS YELLOW-COLOURED (LIGHT IN PHOTOGRAPH); Q STRIATION AND Z LINE ARE DARK

The treated muscle pieces were fixed in 10 per cent formaldehyde and embedded in paraffin. We cut the sections at 10 μ and analysed them by a polarized-light microscope, using a gypsum plate (Red I. + 45°). It was found that the areas penetrated by the solution became negatively birefringent (Fig. 1). With greater enlargement it was noticed that the negative birefringence appears in the J striation, and that positive birefringence disappears, so that the Q striation becomes dark (Fig. 2). Quantitative measurements gave the negative birefringence of the treated fibres as $n_\gamma - n_\alpha = -39 \times 10^{-4}$, of the untreated fibres as $n_\gamma - n_\alpha = +40 \times 10^{-4}$.

The negative birefringent material was called N-material. It is extractable from the J striation with Weber's solution containing 30 per cent urea. The extracted substance showed a strong double refraction of flow. In our control experiments it was established that the N-material is originally in the isotropic striation and is not a product of the action of potassium iodide on muscle proteins. It is evident that the N-material locally compensates the positive birefringence of the contractile-proteins and is the cause of isotropy.

We found the N-material to be identical with the negative doubly refracting and phosphorus-containing structure-protein isolated by I. Banga and A. Szent-Györgyi[5]. It is probably the substance seen in the electron micrographs of muscle fibril made by Hall, Jakus and Schmitt and marked "N stripe".

Tumour Inhibition with Extracts of Urine

FROM time to time, various investigators have reported upon growth-inhibiting and growth-stimulating properties of extracts of urine[1]. The investigations outlined below are being conducted in relation to the extract known as H.11, and it is with the former of these that we are concerned, although we have noted the presence of the latter.

In our experimental investigations, which are directed towards the isolation of compounds with tumour-inhibiting properties, as a preliminary means of recording whether or not an extract is active—and by this is meant its ability or otherwise to produce inhibition or, more desirably, complete permanent regression of tumour growth, without causing measurable toxic condition in the animal under treatment—we have used the Twort alveolar carcinoma.

From a considerable number of fractions tested for tumour-inhibiting properties, we have found that normal male urine, acidified to pH 4 and continuously cold-extracted with toluene, results in a crude extract containing the active agent. A considerable quantity of inactive material, chiefly in the way of pigments, is removed with activated carbon. Absorption of the resulting extract upon activated alumina, and subsequent elution with toluene + 1 per cent ethanol, results in a considerably purified active extract. Of some twenty fractions obtained from the chromatographic analysis, this is the only fraction which has consistently shown the power to inhibit the growth of the Twort alveolar carcinoma. This fraction is partitioned against 60 per cent ethanol, and the active principle is found to be contained in the aqueous alcoholic phase. The dissolved solids contained in this phase are converted into an aqueous colloidal extract, buffered to pH 7, and this extract is at present used for bio-assay.

It is impossible at this stage to give any indication as to the possible chemical nature of the active agent contained in the extract at present employed for bio-assay. The extract is subject to oxidation fairly readily; it exhibits neither œstrogenic nor androgenic activity in either bio-assay or by chemical colorimetric determinations. These facts are supported by adsorption spectra data. Aqueous extracts appear to lose activity after about a month's storage in a refrigerator; stability to heat has been established to 100° C. at 20 mm. pressure in the absence of water. Decomposition occurs at about 60° C. when heated at atmospheric pressure in the presence of water.

Hot hydrolysis of urine under the conditions usually employed for the isolation of sex hormones, and subsequent treatment by the method outlined above, results in an inactive material. Attempts at chemical separation, such as benzoylation, acetylation, half succinate division into alcoholic and non-alcoholic material, Girard division into ketonic and non-ketonic fractions, and the orthodox procedures employed for the separation into acids, bases, phenols (strong and weak) and neutral compounds, have failed to give significant biological results.

Bio-assay has been carried out on a large number of mice, and present indications are that response to treatment is maximal in daily doses of $400\,\gamma$, as measured in terms of total solids. Toxicity tests have been carried out on all fractions prior to bio-assay. Injections were carried out over a period of ten days, response to treatment usually commencing at about the fourth day. The route employed was by intraperitoneal injection, and it has been noted that tumour size does not materially affect the issue, as an extract capable of inhibiting the growth of small tumours has been found equally capable of inhibiting the growth of tumours of larger area and vice versa.

Of a total number of sixty-eight tumour-bearing mice, 33·6 per cent showed varying degrees of inhibition of tumour growth; 36·8 per cent showed partial regressions of tumours; 23·5 per cent showed complete regressions of tumours, and 7·1 per cent showed no response at all; the number of controls being forty-six, and having 4·4 per cent spontaneous regressions.

The fraction employed at this stage of the research has since been further separated into eight fractions, and these are at present under biological and chemical investigations.

We are indebted to Mr. J. H. Thompson, director of research at these Laboratories, for his constant help and encouragement during the course of these investigations, to Dr. O. Pecznick, of the Department of Pathology, for undertaking the bio-assay of the numerous fractions we have produced for examination, and to all other members of the research staff for their continuous interest and helpful discussion.

A Possible Explanation of the Relation between Hereditary Anæmias and Depigmentation in the Mouse

IN mice there are two chief forms of hereditar anæmias, the macrocytic and the siderocytic c flexed tail anæmia[1]. The former is due to one of th dominants W or W^v, the first of which is lethal whe homozygous while the second is viable. WW an W^vW^v animals are white with black eyes, and in th heterozygotes with the normal w the two factors ma or may not show dominance, according to the facto concerned and the genetic background[2]. The othe form of anæmia, the siderocytic, is due to the recessiv factor f and is also associated with depigmentatio All the ff animals show a transitory anæmia at birt and the majority of them have also a white spot o the belly and many times also a flexed tail.

The relations between macrocytic anæmia an total depigmentation on one hand, and siderocyti anæmia and belly spot and flexed tail on the othe have remained obscure and constitute one of the mos puzzling cases of pleiotropic action of genes[3,4]. I has been suggested that in siderocytic anæmia th primary effect might be the anæmia, the other being secondarily induced by a diminished oxyge transport to the tissues[5]. It is also stated, howeve that "there is no foundation in observed facts for th assumption that variegation of the fur is physiologically conditioned by an anæmia"[5].

Nevertheless, it is known that some factors ar common to both hæmoglobin formation and melani production. Among these the factors belonging to th group B vitamins[6] and copper[7] are outstanding. A hepatic extracts have not cured mice with macrocyti anæmias[1] and the action of these extracts is generally associated with group B factors, it seems mor likely that copper is the link between the two kinds o anæmias and pigmentation. In addition to the fac that copper is necessary for normal hæmoglobin production, it must also be remembered: (1) that coppe is the co-ferment (or at least part of the co-ferment of tyrosinase and polyphenoloxidases in general (2) that one of the primary steps in the formatio of melanins is, very probably, the oxidation of compounds with phenolic OH groups by tyrosinase o other phenolases; and (3) that the liver, importan as an embryonal hæmatopoietic organ, and the hai are relatively very rich in copper.

In spotted areas the cells of the hair matrices do no possess the Golgi structures (also called lipochondrie found in pigment-producing hairs[8]. Possibly th could be fixed early in embryonic life by the migratio or non-migration of certain neural crest cells to th affected areas of the epidermis[9]. 15-day old mic embryos already show differentiation of their epidermis so far as concerns the hair follicles, as has bee proved by cultures on chick allantois[10]. Only thos agents acting prior to this time will be expected, therefore, to have an effect upon the production of localize or generalized white spotting. Macrocytic anæmia i known to be plainly manifest at the sixteent embryonic day, and must have appeared several day before. Siderocytic anæmia is apparent at the thirteenth day of embryonic life, while the tail cartilag differentiates partially into fibres at the fourteent to fifteenth day[1]. It seems very probable that th most severe, the macrocytic anæmia, will be found t appear by the twelfth day, when the primitive bloo cells are replaced by intermediate (in the sense use by Grüneberg) and definitive erythrocytes.

As yet we have no data on the exact time of determination of the melanophores in hair follicles, or, which in the end is the same, on the time of differentiation of the Golgi structures characteristic of hair matrices capable of forming melanins. From what has been said above, it is reasonable to expect, however, that this differentiation (after migration, perhaps) will take place by the time that factors W, W^v and f exert their action. If so, a deficiency in a copper compound, necessary both to hæmoglobin production and to the synthesis of phenolase, will have the effect of causing anæmia and a lack of pigmentogenesis in the hair matrices now in differentiation. The difference between the actions of W, W^v and of f probably depends upon the time of action and the intensity of the two kinds of factors, the first acting more early and hindering, therefore, all differentiation of melanoblasts (in heterozygotes sometimes only partially), while by the time f comes into action only the melanophores of the median belly line would be yet undifferentiated. The flexed tail of the ff mice probably is a secondary effect due to the anæmia being at its peak exactly when the fibrous tail structures are differentiating. This seems more probable when it is considered that in mice several factors affect the tail as secondary effects.

The copper compounds upon which the primary action of W, W^v and of f is exerted will be perhaps related in the two cases. As the steps in the synthesis of copper proteins are not known, we must suppose that the compounds involved in the two anæmias and in depigmentation will be perhaps intermediates between ionic copper and cupro-proteins. The primary action of W, W^v and f would be a hindering, more transitory in f, of the synthesis of these compounds.

Relation of the Thyroid to Infections

Izzo and Cicardo[1] have reported an inhibiting effect of thyroxine on experimental tuberculosis in guinea pigs. The experiments were suggested by the chemical resemblance of thyroxine to diploicin, which exerts a bacteriostatic action on *Mycobact. tuber.* But the authors envisaged also the possibility of an unspecifically stimulating effect of the thyroid as an explanation of their experimental results. I should like to direct attention to some earlier observations on the influence of the thyroid on infections in general and particularly on tuberculosis.

Kallos[2] reported on human cases of hypothyroidism suffering from severe pulmonary tuberculosis which exhibited a lowered sensitivity to tuberculin. Treatment with thyroid extract improved the condition and raised at the same time the tuberculin sensitivity. Later, Kallos and Müller[3] found that percutaneous tuberculin tests in general are liable to be intensified by the administration of thyroxine. Bettini[4] observed favourable effects of treatment with thyroid extract on laryngeal tuberculosis.

The observations of Kallos and Müller suggest rather a systemic stimulation of the defence mechanisms than a specific bacteriostatic action. An unspecific stimulation in infectious diseases was attributed to the thyroid in 1929 by Guillaume[5]. Lauber[6] achieved an increased resistance against acute infections by administration of thyroid extract, and Weichardt[7] an inhibition of growth of transplanted tumours. In typhoid patients, Reitler[8] observed a marked rise (two- to fourfold) of the O- and H-agglutinin titre after three days administration of small doses of thyroid extract (twice daily 0·025 gm.), while controls in the same stages of disease showed no titre change after so short a time. Larger and smaller doses had a less marked effect. Such an optimum has been described already by Thaddea[9] in respect of the increased erythro- and leucopœsis caused by thyroxine.

An unspecific factor is, therefore, certainly involved in the effect of thyroxine on the course of infections. As Weichardt thought, it is probably due to the increase in cellular metabolism (personal communication). But it may be that in the particular case of tuberculosis this unspecific stimulation combines with an antibiotic action on the causative organism.

Chromosome Numbers in Cancer Cells

DURING an investigation on the variation of the chromosome system in human cancer of the uterus, we were able to observe frequently (in six epitheliomas of the uterus portio) a mitotic figure with a peculiar aspect of the chromosomes. In such cell divisions (which appear mixed with normal, heteroploid and polyploid ones) 24 chromosomes are present. Their shape resembles the meiotic one, being strongly contracted. The prophase shows thick threads, as in the pachytene stage, and later the synaptic males appear unsplit. No chiasmata are to be seen; the metaphase shows that every element is double.

It seems likely that the result of these divisions may be a reduction of the chromosome number. The cells in which the phenomenon appears are those termed *A* by Caspersson and Santesson[1].

This finding may be connected with the observation in 1906 of Farmer, Moore and Walker[2], and with that by Evans and Swezy[3]. But while the former is generally held to be doubtful, the latter concerns tetraploid cells, where the reduction to haploidy is impossible with a single mitosis. Haploid cells, on the other hand, were actually observed by Koller[4]. Finally, meiosis-like figures were found by Hearne Creech[5] in cultivated mouse fibroblasts previously treated with carcinogenic substances.

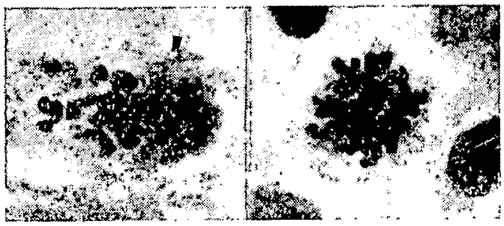

Fig. 1 Fig. 2

Fig. 1. METAPHASE PLATE IN A CANCER CELL, WITH 24 PAIRED CHROMOSOMES. SMEAR STAINED WITH ACETOCARMIN. × c. 1,000

If the pairing chromosomes are unsplit in the early prophase, the phenomenon might be compared with the early leptotene according to Darlington, and the nuclear precocity might be explained as the result of the general upset of the nucleic acid cycle in the malignant cell already pointed out by Caspersson and Santesson[1].

Chemical Composition of Egyptian Cow's Milk in Relation to Milk Laws

AN investigation of the composition of cow's milk in Egypt has been undertaken through seven lactation seasons, from 1937 to 1944, involving 2,817 samples. The cows were those forming the herd of the Faculty of Agriculture; most of them were born and reared in the farm of the Faculty, and the rest were bought from lower Egypt. A wide variation in constituents has been shown, and this is due to the lack of particular breed and to the seasonal variations. The accompanying table shows the total average of milk constituents, their maximum and minimum, and the extent of increase and decrease above and below the average:

	Density	Fat %	Solids (not fat) %	Total solids %	Water %	Fat / T. solids %
Average	1·0315	4·87	9·11	13·98	86·02	34·72
Maximum	1·0375	9·25	10·57	18·73	89·76	50·80
Increase %	19·05	89·94	38·53	33·98	4·35	46·31
Minimum	1·0230	2·00	7·06	10·24	81·27	15·03
Decrease %	26·98	58·93	22·50	26·75	5·52	56·71

Owing to the great variations in the composition of milk it seems difficult to prove that a milk sample is adulterated by either adding water or separating cream. It is due to these wide individual variations that a genuine sample with a very low amount of fat can be considered legally adulterated according to the present milk regulations in Egypt. The present limits for cow's milk in Egyptian milk laws[1] are the same as those applied in Scotland, and all the conditions are quite variable. These laws state that if fat and solids-not-fat are less than 3 per cent and 8·5 per cent respectively, the sample is suspected of being adulterated. In Scotland, Tocher[2] found these figures after a study of 676 milk samples, in which case the average fat was found to be 3·95 per cent and average solids-not-fat was 8·78 per cent. He further found that fat of 56 samples (8·38 per cent of animals) was less than 3 per cent, and this is the least limiting figure to determine whether a sample was genuine or not. 167 samples (24·70 per cent of animals) also had solids-not-fat less than his average figure 8·5 per cent.

Our data show that the average fat content in the 2,817 samples was found to be 4·87 per cent. Out of this number of samples only 26, or 0·92 per cent, of the whole samples gave fat figure less than 3 per cent. The same happened in solids-not-fat, where the average figure was 9·11 per cent, and only 625 samples (22·15 per cent) showed less than 8·8 per cent. The lowest limiting figures of Tocher could therefore not be applied to Egyptian cow's milk. If the number of animals was taken into consideration, Tocher based his 3 per cent on 8·38 per cent of animals. On the same lines, from the fat distribution, it is worthy of note that 94 samples, or 3·33 per cent, showed fat content less than 3·5 per cent, and 219 samples, or 7·78 per cent, had a fat content less than 3·80 per cent. Hence, it is more reasonable in Egypt to consider the lowest limiting figure of fat nearly about 3·80 per cent, certainly not 3·0 per cent. As regards solids-not-fat, Tocher found that the average figure was 8·87 per cent, and the least limiting figure was 8·50 per cent for 24·70 per cent of animals. If such lowest figure was applied in our herd it would correspond to 8·01 per cent of samples; hence it is quite fair to consider the lowest limiting figure 8·80 per cent, which corresponds to 22·15 per cent of the samples.

It is therefore more correct to consider in the Egyptian milk regulations the lowest figure of fat to be 3·80 per cent and of solids-not-fat 8·80 per cent, instead of 3·0 per cent and 8·50 per cent respectively. To these can be added the total solids and the ratio of fat to total solids; the former should be 12·60 per cent and the latter 30·10 per cent.

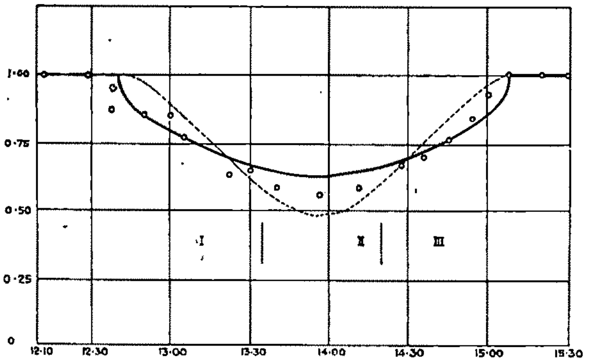
Radio Noise from the Sun at 3·2 cm.

IN connexion with Dr. Martyn's recent communication[1], the following measurements made by me at Malvern during the partial eclipse of July 2, 1945, may be of some interest. They were made at a wavelength of 3·2 cm., using an apparatus similar in principle to that described by R. H. Dicke[2] in conjunction with an antenna consisting of a wave-guide-fed paraboloid 3 ft. in diameter. The beam width was about 2°.

The results obtained are shown in the accompanying figure, together with two comparison curves. The full curve represents the fraction of the sun's circumference, and the dashed curve the fraction of area of the sun's disk exposed during the course of the eclipse.

The weather divided the experiment into three periods. During period I there was heavy cloud



Hours G.M.T.
——, fraction of sun's circumference exposed ;
- - - -, " " " area " ;
o, experimental points ;
Absolute value of sun's radiation = 4×10^{-18} watts/mc./s./cm.[2]

almost totally preventing visual alignment. A time constant of 1 sec. on the output meter rendered electrical alignment rather difficult, so errors due to misalignment may be present. In period II atmospheric absorption was appreciable, rain fell and eventually stopped measurements for a while. Measurements of atmospheric absorption were made together with the solar measurements, and correction applied, but the results may quite possibly be too low. In period III measurements were started again with visibility rapidly improving, and frequent visual sights were made.

Although the observed values do not fit one curve better than the other, there are at least two factors which must be considered. First, even if all the noise originates at the sun's circumference, the source would not be of infinitesimal width, and some rounding off of the sharp corners of the full curve would be expected. Secondly, it is to be expected that some noise comes from the whole disk, and the trough would thus be deepened to a certain extent. The accuracy of the measurements does not warrant much effort in deducing the detailed distribution of the noise sources, but they do indicate that the sources are mainly located about the circumference.

The value of the total radiation from the sun was found to be 4×10^{-18} watts/mc./s./sq. cm.

I wish to thank the Chief Scientist of the Ministry of Supply for permission to publish these results.

Crystal Structure of a Crossed-Chain Potassium Soap

IT is generally assumed that hydrocarbon chains in soaps all lie parallel to each other, although experimental evidence on this point has hitherto been lacking. Soaps crystallize in a bewildering variety of crystalline forms[1], and whereas the axes of the chains may lie parallel in some forms, they do not necessarily do so in all of them.

In the case of potassium soaps, we have encountered at least three forms, provisionally designated A, B, C of anhydrous, and one form D of hydrated, neutral even-numbered potassium soaps, each giving a different characteristic X-ray powder pattern. The form A is monoclinic, and was obtained for soaps with 4–12 carbon atoms in the chain ; long spacings d measured in kX. obey a formula, $d = 5{\cdot}70 + 2{\cdot}165 N$, where N is the number of carbon atoms in the chain. The angle of tilt between the chain axes and the (001) plane (calculated from the increment, assuming tetrahedral angle and carbon to carbon bond-length 1·54 kX. in the chain) is therefore 59·4°.

The form B is probably triclinic ; it was obtained for soaps with 12–18 carbon atoms per molecule. Long spacings obey the law $d = 6{\cdot}80 + 1{\cdot}95 N$; the angle of tilt is therefore 50·7°.

The form C was observed only at higher temperatures, and the hydrated form D at lower temperatures ; they have not yet been studied in sufficient detail to warrant description. Piper[2] reports only one form each of neutral and acid potassium soaps, and the neutral soaps of longer chain-length investigated by him may be identical with our form B.

We were fortunate in growing a few single crystals of the monoclinic form A of potassium caprate ($KC_{10}H_{19}O_2$), large enough for a single-crystal X-ray examination, and prepared Fourier projections along the a and b axes. They revealed that in this form of soap the molecules are in general positions and the hydrocarbon chains cross each other at an appreciable angle.

The crystals were grown from ethanol by very slow evaporation over calcium chloride. They are extremely thin plates, the large face being {001}, with malformed edges. They are stable on exposure to the dry air, but disintegrate (probably forming the hydrated form D) when exposed to air of ordinary humidity at temperatures below room temperature. Dehydration experiments showed that they are anhydrous.

Rotation, oscillation and moving film photographs were taken about the a and b axes using copper $K\alpha$ radiation. The crystal is monoclinic and the unit cell dimensions are : $a = 8{\cdot}09$ kX., $b = 5{\cdot}63$ kX., $c = 28{\cdot}81$ kX., $\beta = 108°$, d (001) = 27·40 kX. ; density (meas.) 1·123 gm./c.c., (calc.) 1·112 gm./c.c. (assuming four molecules per unit cell) ; halvings observed were : ($h0l$) absent when h is odd ; ($0k0$) absent when k is odd ; therefore, the space group is $C_{2h}^{5} - P\ 2_1/a$.

The intensities of the reflexions were estimated by eye and the signs of most of the structure factors determined by trial and error. In the Fourier projection along the b axis, the plane zigzag hydrocarbon chains project parallel to each other and edge on. Moreover, owing to a component of tilt in the plane perpendicular to the plane of projection, pairs of carbon atoms of the same chain overlap, with the exception of the terminal groups. The electron density distribution is consistent with the zigzag configuration, and, assuming the usual interatomic angles and distances, approximate x and z co-ordinates have been determined. The component of the angle of tilt projected along the b axis, measured from the a-axis, is approximately 102°. In the Fourier projection along the a axis the chains are seen face-on and form a criss-cross pattern, one chain making on the projection an angle of about 58° ; the other, in conformity to the symmetry of the crystal, an angle of about 122°, both measured from the b-axis. The co-ordinates of the atoms are being refined.

We are indebted to Dr. J. Iball for valuable advice, and to the director of the Chester Beatty Research Institute of the Royal Cancer Hospital (Free) for the loan of some apparatus. We wish to thank the directors of Lever Brothers and Unilever Ltd. for permission to publish these results.

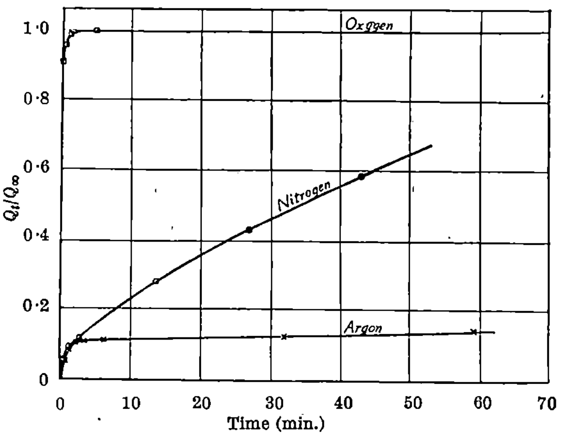
Molecular Sieve Action at Low Temperatures

BY using crystalline network lattices with uniform interstices as sorbents, it has proved possible to carry out a great many resolutions of molecular mixtures[1]. Molecules which are of the right dimensions to enter and occupy the intra-crystalline interstices are then removed by selective sorption, leaving behind molecules which are too large or have the wrong shape, and hence toward which the network lattice is a non-sorbent. Crystalline parameters define with precision the dimensions of the interstices (which are linked to give channels); and, therefore, the molecular sieve action is equally clearly defined. As a result separations become quantitative in numerous instances (for example, *n*-paraffins from *iso*-paraffins using dehydrated chabazite as sorbent).

Between these two extremes lies a transition group of molecules which work their way slowly into the crystal by a process of activated diffusion[1]. Indeed, there is a complete range of velocities of sorption between the extremes. Some molecules are sorbed rapidly at room temperatures, but more slowly at −78° C. (for example, argon and nitrogen in calcium and barium mordenites). Then one finds a very low energy of activation for diffusion[2]. (This energy of activation is not due to chemical forces, but is a reflexion of the periodic potential energy field in the crystal encountered by the molecule as it moves from one site of maximum sorption potential to the next.)

It has now been found that the molecular sieve behaviour can be extended considerably by sorbing those gases with a small energy of activation for diffusion at still lower temperatures (−183° to −195° C.). In this way, for example, using a suitable molecular sieve sorbent, great differences in the sorption-rates of oxygen, nitrogen and argon were found, which seem quite sufficient to permit quantitative or semi-quantitative resolutions of their mixtures. The sorption-rates at − 184° C. were as expected in the order oxygen > nitrogen > argon, in the inverse relation to the dimension important for diffusion down a narrow interstitial channel, namely, the cross-sectional diameter normal to the molecular axis in oxygen and nitrogen molecules, and the diameter of the argon atom respectively[1,2].

As an illustration, the accompanying graph shows the relative amounts of argon, nitrogen and oxygen sorbed by 1 gm. of dehydrated levynite at − 184° C. at various times. Apart from a small and rapid sorption on external surfaces of the crystal powder, argon is sorbed at a very slow rate. Moreover, if a mixture of argon and oxygen were passed through the powder at − 184°, by adjusting the time of contact to one or two minutes, one would here expect a 99 per cent removal of oxygen from the mixture.



WIDELY DIVERGENT SORPTION-RATES IN DEHYDRATED LEVYNITE AT − 184° C., DUE TO THE MOLECULAR SIEVE ACTIVITY OF THE ZEOLITE

Q_t denotes c.c. sorbed at N.T.P./gm.

Q_∞ denotes sorption at equilibrium in c.c. at N.T.P./gm.; oxygen, 10·02 c.c./gm.; nitrogen, 9·77 c.c./gm.; argon, 10·13 c.c./gm.

Such contact times would also give a good separation of nitrogen from oxygen. These results, particularly on argon – oxygen mixtures, should be of interest to the argon industry, and the liquid air industry. The experiments also demonstrate for the first time that levynite, like chabazite[3], gmelinite[2], mordenite[2] and certain synthetic zeolites[4], has molecular sieve activity.

A full account of these and other results will be published elsewhere.

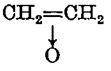
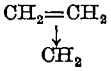
Structures of Ethylene Oxide and Cyclopropane

IT has recently been suggested by Walsh[1] that the structures I and II represent the properties of ethylene oxide and cyclopropane better than do the classical formulæ III and IV. In these new structures the oxygen atom in I, and the CH_2 group in II, are attached to the double bond by a dative link formed from the π-electron pair of the 'ethylene' portion of the molecule. These ideas were apparently put forward because Zimakov[2] has lately pointed out that the classical Würtz formula for ethylene oxide does not adequately account for its high reactivity; also because formula IV gives no indication of the characteristic reactivity of cyclopropane.



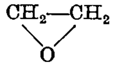
$$\underset{\displaystyle O}{\overset{CH_2{=}CH_2}{\downarrow}}$$

I

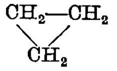


$$\underset{\displaystyle CH_2}{\overset{CH_2{=}CH_2}{\downarrow}}$$

II



III



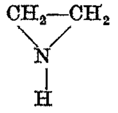
IV

The conception of π-electron dative bonds is due originally to Dewar[3], and though it does help to explain certain molecular rearrangements, its use in the suggested structures makes it difficult to reconcile these with the known Raman and infra-red spectra of ethylene oxide and cyclopropane. If the double bond in structures I and II has the properties usually associated with such a linkage, then both these compounds should show a strong Raman band (polarized) in the region of 1,600 cm.$^{-1}$ due to the $>C = C<$ vibration: in ethylene[4] this band occurs at 1,623 cm.$^{-1}$.

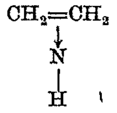
Both structures I and III belong to the point group C_{2v}; the irreducible representations for vibrations of this point group are $5A_1+3A_2+4B_1+3B_2$, of which all are allowed as fundamentals in the Raman spectrum, while the A_2 vibrations are forbidden in the infra-red spectrum. The A_1 vibrations in the Raman spectrum are polarized, hence if structure I were correct we should also get a band in the infra-red spectrum in the region of 1,600 cm.$^{-1}$. The Raman and infra-red spectra of ethylene oxide[5], and of the related ethylene sulphide[6], are well known; but there are no Raman bands near 1,600 cm.$^{-1}$ in the spectra of either of these compounds; and the observed spectra are in conformity with the requirements of the symmetry group C_{2v}.

Cyclopropane as represented by structure IV belongs to the point group D_{3h}, which has as irreducible representations $3A_1' + 1A_1'' + 1A_2' + 2A_2'' + 4E' + 3E''$, of which the A_1'', A_2'', and A_2' vibrations are forbidden in the Raman spectrum and only the E' and A_2'' vibrations allowed in the infra-red spectrum. The A_1' vibrations in the Raman spectrum are polarized. The Raman and infra-red spectra of this compound have been examined by a number of workers[5], and the experimental results confirm these deductions. Again, no Raman line is found near 1,600 cm.$^{-1}$.

Further, and perhaps more conclusive evidence, could be obtained if the Raman and infra-red spectra of ethyleneimine V were examined; for if this compound has a π-electron dative bond as in VI, then the frequency of the N—H vibration should be different from the value usually found for this linkage when the nitrogen is part of a heterocyclic system.

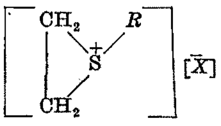


V



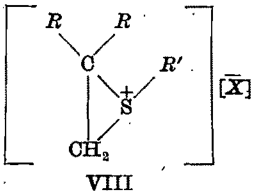
VI

From the purely chemical point of view, there is also evidence against a π-electron dative bond in these substances, for Delépine[7] has found that ethylene sulphide forms crystalline sulphonium compounds of the type VII.



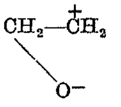
VII

In this connexion it is interesting to note that the sulphonium ions of compounds of the type VIII are asymmetric and should exhibit optical isomerism, since they are analogous to those organic sulphur compounds which have been successfully resolved[8]. In fact, if compounds like VIII were resolvable, it would be strong evidence against the occurrence of a π-electron dative bond in ethylene sulphide.

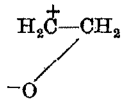


VIII

Thus, though structures I and II are suggestive, it is difficult to accept them as representing ethylene oxide and cyclopropane. In the case of the former there seems no reason, at the moment, to go beyond Zimakov's suggestion that it be regarded as a resonance hybrid in which structures IX and X predominate.



IX



X

This would account adequately for the reactivity of this substance and yet be consistent with the known Raman and infra-red spectra. The reactivity of cyclopropane could also be ascribed to resonance between analogous structures.

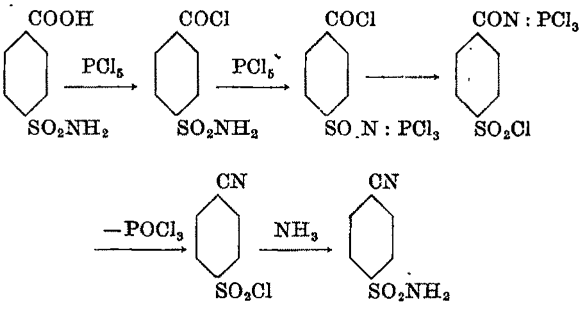
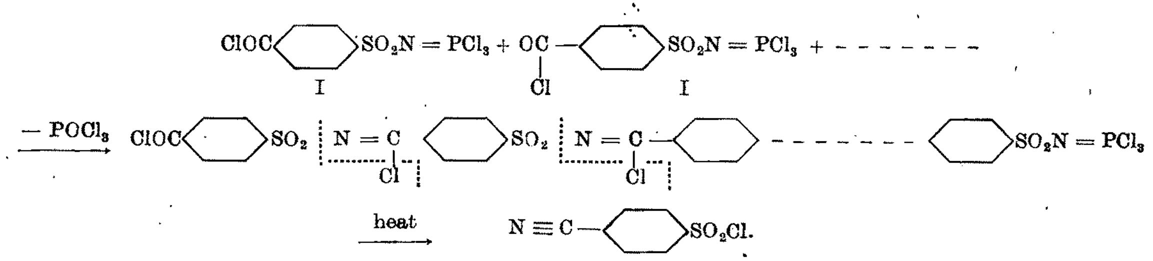
Action of Phosphorus Pentachloride on *p*-Sulphonamido Benzoic Acid

Remsen *et al.*[1], in the preparation of *p*-sulphonamido benzonitrile from *p*-sulphonamido benzoic acid by the action of phosphorus pentachloride, postulate the following mechanism of reaction:



They remark on the shift of the nitrogen from the sulphone group to the carbon atom attached to the para position of the ring, but do not explain it. The following explanation of the mechanism is offered.



ClOC SO₂N = PCl₃ + OC SO₂N = PCl₃ +
Cl
I
I
I
− POCl₃
ClOC SO₂ N = C SO₂ N = C SO₂N = PCl₃
Cl
Cl
heat
N ≡ C SO₂Cl.

It is supposed that several molecules of the chloride (I) condense as indicated to form polymers, phosphorus oxychloride being eliminated. The resultant polymer then breaks down on further heating, to give the required *p*-sulphonamido benzonitrile. In support of this hypothesis, compounds of the type $R.SO_2N{=}C(Cl)R'$ are known to dissociate on heating as follows[2,3,4]:

$$R.SO_2N{=}C(Cl)R' \rightarrow R.SO_2Cl + R'CN.$$

A Proposed Test for 'Sterilized' Milk

THE need for a simple and satisfactory test to indicate the probable keeping quality and sterility of 'Sterilized' milk is becoming increasingly urgent. The phosphatase test of Kay and Graham may not always give satisfactory results when applied to 'Sterilized' milk because the reaction is affected by products produced in the milk as a result of the severe heat treatment.

The most common and important type of spoilage of 'Sterilized' milk is sweet curdling[1]. This fault may occur in bottles of milk with the vacuum unimpaired in as short a period as three days after sterilization. The organisms responsible are usually atypical forms of *B. cereus* and *B. subtilis* which produce a rennin-like enzyme and, also, because of the reduced oxygen tension in the milk, carbon dioxide. The heat treatment to which the milk is subjected (at least 212° F. for a period of not less than 10 minutes) causes a decrease in the amount of soluble calcium, but the carbon dioxide produced by the organisms renders sufficient of the calcium soluble for the rennin to clot the milk.

Types of spoilage which occur with less frequency are the development of 'oxidized' or 'cardboard' flavour due to the presence of large numbers of *B. circulans*, which also appears to produce a rennin-like enzyme in milk, and 'bitter' flavour which is produced by *B. thermoacidurans*.

It has been shown that the alcohol test can be used to indicate the keeping quality of raw milk, and that milk containing a large number of rennet-producing organisms can be detected by this test[2].

From these researches it appeared feasible that the alcohol test might be modified to indicate the keeping quality of 'Sterilized' milk. Preliminary experiments have shown that when milk containing spores of *B. subtilis*, *B. cereus* or *B. licheniformis* after sterilization is incubated at 37° C. for 27 hours and then tested by the alcohol test using 80 per cent (sp. gr. 0·848) alcohol containing 0·02 per cent neutral red, those samples which gave a precipitate developed bitterness or sweet curdling within a period of three weeks when held at room temperature, that is, the period within which the milk may be held before sale to the public. If in addition to the precipitate there is an acid reaction, it is probable that the milk is contaminated with streptococci which have gained entrance to the milk after heating, or with acid-producing sporing aerobes such as *B. albolactis* (Mig.) and *B. thermoacidurans*. These organisms are, however, not commonly found in 'Sterilized' milk. On the other hand, if the reaction is slightly alkaline, the contamination is probably due to spore-forming organisms present in the bottles before they were filled with milk.

These preliminary experiments will require to be extended in order to define the exact correlation between the results of the test and the keeping quality of the milk.

Influence of Heteroauxin on the Cotyledons of *Phaseolus vulgaris* L.

I THINK it is only right that attention should be directed to certain facts concerning the communication from A. Malabotti, published in *Nature* of December 14, 1946, under this title. The work described there, far from being recent, was carried out at the Biological Research Institute of the Academy of Science in Vienna more than ten years ago, when I was director of the Institute. Malabotti was one of my students, and the work was done at my suggestion and under my supervision to supplement my own experimental work on the same subject. Accounts of the work have already been published by Malabotti[1] and myself[2,3]. A comparison of Mr. Malabotti's communication in *Nature* with my paper of 1937 shows that it is an almost literal translation of the latter, with the addition of two photographs and their explanations.

Since 1939 I have been working at the Jodrell Laboratory at the Royal Botanic Gardens, Kew, and, during part of this time, have continued my researches on the effect of heteroauxin on *Phaseolus vulgaris*, a full account of which was published[4] with due acknowledgment to Malabotti for his past collaboration.

SCIENCE AND THE REAL FREEDOMS

THE critical economic situation in which Britain finds herself requires all possible scientific help. The contribution of men of science can be as vital to our national recovery as any gains won by the miners in the battle for coal. But this depends on whether men of science are in a position to act, and whether their efforts are properly organised and integrated on a national scale.

The speakers at a recent conference on "Science and the Real Freedoms" convened by the Association of Scientific Workers dealt with these issues so far as they affect the freedom of men of science to develop their knowledge and the opportunity to see it applied to the main economic problems of the country. In opening the meeting, Sir Robert Watson-Watt pointed to the substantial progress that has been made towards the planning of scientific effort. Members of the Association particularly welcome the formation of the committees for military and civil science under the chairmanship of Sir Henry Tizard. Also encouraging are the scientific organisation within the National Coal Board and the provisions of the Industrial Organisation Bill. But still there remain severe limitations on the development and use of science, which we would be unwise to ignore.

The scale and nature of the effort applied to the development of new weapons of war, which offer us the possibility of mass destruction of quite unprecedented extent, is a source of disquiet. The man of science, as a key man in this development, works behind the screen of military security, cut off from free intercourse with other scientific workers by dangerously ill-defined and ill-conceived secrecy restrictions. The Official Secrets Act, which someone once quite seriously described as "the Act to repeal Magna Carta", is singularly unclear in the burdens, often of retrospective responsibility, which it puts on State servants and ordinary citizens alike. Safeguards are essential, but they should be specific, clear, comprehensible and limited. At present it seems that timid minds are imposing a stricter and more extensive secrecy than is necessary, with the result that our own scientific progress is perhaps hampered as much as that of a potential enemy.

Restrictions, Sir Robert said, are not confined to the military field. It is the habit of industrialists to accuse the bureaucrat of an exclusive taste for restrictions. However, they themselves must take some of the blame for certain economic shortcomings. For a long time sections of industry have imposed limitations on the development and interchange of new ideas and techniques, occupied research workers on circumventing the patents of others, and used blocking patents of their own to ward off the necessity of making new capital investments.

Talk on 'freedoms' has been too much directed to the passive freedoms, 'freedoms from'; and too little to the active freedoms, 'freedoms for' and 'freedoms to'. While men of science have been accustomed to claim for themselves the right to choose, to learn, to read, speak, think and write as they will, they have not put enough effort into the harder task of winning the freedom to investigate, to study scientifically within the industries themselves and by their own methods the problems which they consider important to the life of the community. The scientific worker in industry is seldom given the chance to investigate adequately the problems of production and development in his section of industry, nor is he in a position to undertake the full application of war-time discoveries to production techniques. There is clearly an urgent need of extension of freedom to penetrate in this direction.

Sir Robert Watson-Watt ended with a word of caution. It should be remembered that the outcome of any project of scientific research is unforecastable. As men of science we cannot say explicitly at the outset what may be expected from the investigations which we feel we must be free to undertake. The user does not know what to ask for; the investigator does not know what he can promise. But as to the great advantages which will arise from the organised application of research and scientific method, we have no doubts and many proofs. The opportunity which men of science now have of proving the value of their methods in overcoming our economic difficulties must not be lost.

Dr. E. H. S. Burhop, former member of the British team of atomic scientists in America, spoke of the loss of what might be called the natural rights of men of science. Such men have advanced fundamental knowledge in the past, because there have been free exchange of information and collaboration across frontiers and between workers in the different branches of science. Now secrecy has split them in camps, and the ominous delay in ending it is a symptom of the preparation of another world war. In view of the great dangers involved, the Association of Scientific Workers feels that it is time for men of science to decide what they can do collectively and individually to better this situation.

To one who has come to recognize a traditional fairness in British justice, some of the provisions of the Official Secrets Act are alarming. Under it the normal rights of citizens to a fair trial are superseded, and the onus of proof of innocence is placed on the accused. It is not necessary, Dr. Burhop said, for the prosecution even to prove that any specific offence has been committed; only that the character of the accused makes it appear probable that he has committed such an offence. Moreover, many people are under the misconception that this Act applies only to those in Government service. In fact it applies to everyone in the country.

We have, as a warning of what might happen, the hysteria and false accusations which followed the revelations of a spy-ring in Canada. There is also the case of Dr. Nunn May, which arose similarly out of the secrecy Britain and the United States have imposed on the atom bomb. While the Association does not condone his offence, to which he himself had pleaded guilty, it did feel justified in asking for a marked reduction in his ten-year sentence. If the harshness of this was intended as a deterrent on other men of science, it was a success in so far as it made many have second thoughts about taking any part at all in the development of atomic energy in Britain.

Dr. Burhop recalled the circumstances of the ban placed on certain British and American scientific workers from travelling to Moscow, when the war with Germany had ended, and the Japanese war was in its last stages. He doubts if any atomic physicist would even now have the temerity to apply for permission to travel to the U.S.S.R. or Eastern Europe. As new techniques of mass destruction are developed, the ban might involve other scientific workers besides the atomic physicists.

The Association advocates the complete publication of all results of scientific research, which has been suppressed for reasons of military security, as soon as the Security Council is operating a plan which outlaws the use of weapons of mass destruction, and which provides for a general reduction and control of armaments. Even while the present situation continues, secrecy should be confined to certain technical aspects of weapon development. As a means of re-establishing wide international relations, continued support for U.N.E.S.C.O. and for the recently formed World Federation of Scientific Workers is essential. Moreover, men of science, including those working on atomic energy, should be allowed and encouraged to visit workers in other countries.

We have to be vigilant concerning national restrictions on the freedom of men of science. Under the Atomic Energy Act scientific workers have no well-defined rights of access to scientific information connected in any way with atomic energy. Decisions on these matters depend on the Minister of Supply and his official advisers, and the effects of these decisions will have to be carefully watched. Wherever they work, men of science should have a legal right to the publication of their results. All should be employed on the basis of service contracts, in which are clearly defined their rights and duties in their particular job.

Prof. J. D. Bernal opened his address with the words: "The real freedoms of science not only include freedom from crippling restriction, but freedom to give of one's best in the service of the community. Such freedom is more than individual freedom. It is a collective freedom implying organisation of scientists by scientists in relation to all aspects of national activity."

There is nothing essentially new in the serious economic situation which confronts us to-day. As a culmination of our failure to organise and use our scientific resources efficiently, it has proved conclusively our worst fears and forecasts. Only men of science can see where and for what purposes they themselves are needed. It will be on their own initiative that they will take part in the national recovery.

The White Paper on the economic situation is no more than an able diagnosis of the trouble. When it comes to the cure, all it offers are pious hopes. Unless there is energetic planning, even the necessary minimum of a 40 per cent increase in exports will not be realized. On top of this the international situation looks as though it might get worse in the coming year.

In maintaining our present foreign policy we are keeping 1½ million of our twenty million workers in the Armed Forces. About half a million more are engaged on the production of military supplies. The wastage is relatively greater when one considers our scientific man-power. At the present time about one half of the governmental scientific expenditure is allocated to military research, and clearly the ending of war preparations would release a larger proportion of scientific workers for productive work.

The essential and most urgent need is to consider the best way of organising scientific effort for helping to solve the short- and long-term problems facing us in the industrial sphere in Great Britain. We need a similar organisation and status to that of the operational research teams during the War. This is essential both in those Ministries responsible for our industries, and within the national development councils envisaged under the Industrial Organisation Act. In addition, men of science are needed at Cabinet office level working in co-operation with the Joint Planning Staff. The existence of the Tizard Committees provides the nucleus for such a scientific general staff.

In all this, it is clear that men of science can only analyse the situation and advise on the best policies to pursue. They can provide knowledge on which wise action could be based, but not the action itself. It is up to the Government to take adequate powers to ensure the implementation of the policies decided upon.

About the responsibilities of men of science, Prof. Bernal urged that they take active steps to ensure the widest possible knowledge of the technical situation of the country. The Tizard Committees cannot become fully effective in a normal Civil Service atmosphere, unless there is a possibility of mobilizing public opinion for research and against obstruction. It needs sustained activity on the part of scientific workers to see the necessary plans through to successful completion.

In the discussion, two delegates from the Amalgamated Engineering Union spoke of the attitude of the factory workers to scientific developments. The workers do not take kindly to innovations when, as in one factory, output was trebled but wages scarcely raised. Nor can they easily understand the attitude of the man of science, when he speaks of the importance of freely sharing his knowledge. In the artisan class, particularly, there is a tendency not to pass on information, since in times of unemployment only the most skilled and valuable men keep their jobs. It is necessary for the men of science to explain their methods and to prove their value to the working people. In that way they would win the willing co-operation of the trade union movement.

HEREDITARY (SEED-BORNE) SYMBIOSIS IN *CASUARINA EQUISETIFOLIA* FORST.

By Prof. S. R. BOSE

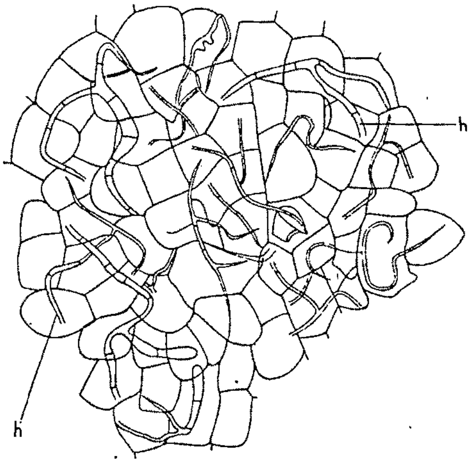
Carmichael Medical College, Calcutta

EVERY *Casuarina equisetifolia* plant examined has been found to have mycelia of *Phomopsis casuarinæ* F. Tassi extending throughout into every organ, beginning from the seed-coat. Cutting a section of the seed-coat of *Casuarina* and staining in picro-nigrosin or cotton blue one can see finely branched and septate hyphæ within the tegmen (see accompanying illustration). Only the resting embryo with two cotyledons is free from fungal infection. In samples of tomato and apple seeds from some apparently healthy fruits from Calcutta markets, I have seen a network of copiously branched and septate hyphæ in the tegmen under the microscope. Dennis[1] recently remarked that "fungi capable under favourable circumstances of parasitizing economic plants such as potato, tomato and apple may be found in nature as saprophytes on herbaceous weeds". I wonder whether Dennis had examined microscopically sections of clean seeds of the various economic plants to locate any possible *Phoma* hyphæ within the tegmen before planting them in the virgin soil. Oxley and Jones[2] found, under the epidermis of maize seeds, and seeds of many samples of English wheat and some Canadian wheat, abundant mycelia in the vegetative condition which they have not been able to identify nor to bring out in pure culture. In some samples of local wheat and maize seeds and some American maize, I have also obtained distinctly septate and branched hyphæ beneath the testa within the tegmen; from a maize sample *Ascochyta* sp. has been isolated in pure culture in malt agar tube, the seed germinated well in the course of five days and the fungus came out with two-celled, oblong and muticate conidia. Bessey[3] and Dennis[1] regard *Ascochyta* as essentially a *Phoma* with two-celled conidia. It would be of interest to know the function of these hyphæ within the seed coat, whether they have any connexion with germination and growth of the wheat and maize plants.

For a number of years I have had opportunities of examining roots, stems, green branchlets, cones, young fruits and fruit-stalks, seeds—young and mature—of *Casuarina equisetifolia* trees of different ages and from different areas of Bengal, Bihar, Orissa, Madras, Bangalore, etc., including a large number of healthy seedlings raised in the nursery of the Royal Botanical Garden, Calcutta, and later I received fruits, seeds and branchlets of *Casuarina equisetifolia* from Australia (Queensland and Brisbane), mainly through the kindness of Dr. J. McLuckie. In each case the same type of fungus (hyphæ of *Phomopsis casuarinæ*) was found co-extensive with the growth of the plant, occurring practically in every organ of the plant.

The results of my experiments with a number of seedlings of *Casuarina equisetifolia* in humus soil with pure culture of *Phomopsis casuarinæ*, as well as experiments to lower the physiological condition of pot-plants by keeping them confined within a glass chamber for about two weeks, confirm the observations of Melin[4] and How[5] that the physiological condition of the host determines the nature of relationship between the two partners in a mycorrhizal association; very weak seedlings in a moribund condition and pot-plants in abnormal condition were killed outright by the fungus, which became strongly virulent and parasitic, while slightly weak but normal seedlings were greatly invigorated by the fungal inoculation, thus establishing examples of well-balanced mycorrhizas. According to Roger Gosselin[6], *Polystictus circinatus* begins as mycorrhizal growth in the roots of spruce during the early period and stimulates the growth of the host plant; ultimately it travels towards the butt of the tree and produces butt-rot. He found that butt-rotted trees have a greater rate of growth than those not rotted, and could produce evidence of mycorrhizal association by inoculation of spruce seedlings with pure culture of *P. circinatus*. This case runs somewhat parallel to that of *Phomopsis casuarinæ* in *Casuarina equisetifolia*, where the fungus first begins as a symbiont but ultimately brings on death of the plant or, in cases, some of its parts, as a parasite; finally, it persists as a saprophyte to be succeeded by *Ganoderma lucidus*, *Fomes senex*, *F. durissimus*, *F. fastuosus*, *Polyporus calcuttensis*, etc., as members of a fungal complex.

Hahn's[7] experience with fruiting bodies of *Phomopsis juniperovora* on *Juniperus virginiana* was that, on vigorous plants growing in the open, the fungus could not be traced in spite of a careful and intensive search, but on suppressed cedars growing in a damp situation in the Platte River or on their withered and dead branchlet-tips the parasite could be found, and abundant fruiting was readily detected on blighted branchlets of a number of cedars used as hedge-plants and on transplant nursery stock used for ornamental purposes; all these observations led Hahn to suspect "if the cedar blight is seed-borne". In this connexion one might refer to the experience of Shear and Wood[8], who have demonstrated the presence of latent infection by *Glœosporium* and *Colletotrichum* in leaves, stems and fruits of a number of plants apparently healthy, and to the experience of Campbell and others[9] in oak heart-wood, where they frequently encountered a number of non-decay-producing fungi and some from apparently sound heart-wood; the exact cause of their presence cannot be ascertained, though it has been surmised that they might have some effect on entrance and subsequent spread of heart-wood-decaying species as forerunners of a fungal complex. Strasburger[10], discussing swellings on leaves of tropical plants belonging to the families of Rubiaceæ and Myrsinaceæ, due to infection by bacteria, has observed that these bacteria are present in the embryo of the plant, and that when these bacteria are artificially kept from the egg-cell, the development of *Ardisia* is abnormal. Parkin[11] has described a curious symbiosis between the fungus *Stereum sanguinolentum* and two siricid woodwasps; he asks why, of many and similar soft wood-attacking fungi, should *Stereum sanguinolentum* only be associated with these two woodwasps? Evidently these problems require further investigation.



PORTION OF THE TEGMEN OF SEED OF *Casuarina equisetifolia* SHOWING SEPTATE HYPHÆ (MARKED *h*) OF *Phomopsis casuarinæ*, CAMERA LUCIDA SKETCH AT TABLE-LEVEL WITH LEITZ EYEPIECE NO. 5 AND OBJECTIVE NO. 7. (× c. 275)

Besides the fungus (*Phomopsis casuarinæ*), *Casuarina equisetifolia* bears coralloid roots or nodules due to infestation of the bacteria, *Rhizobium casuarinæ*, nov. sp. Dowson, which, according to A. Blake[12] and others, fix considerable quantities of nitrogen from the air. The roots of the plant also possess root-hairs at their growing ends. The fungus probably absorbs ammonia salts and complex organic nitrogen-compounds such as nucleic acid and peptone, and transfers them to the roots, as held by Melin[4]; probably auxins and vitamins accumulated by hyphæ are translocated to the roots (cf. MacDougal and Dufrenoy[13]), and the molecular nitrogen fixed by bacteria (amino-acid) is probably made available throughout the body of the plant; the fungus in return gets its supply of carbohydrates from the tree and of phosphatids exuded by its roots. The evidence for nitrogen-fixation from the air by the fungus is very meagre and is not of much consequence. Thus, it is a clear example of close co-operation among the three—the plant, the fungus and the bacteria—for successful and healthy growth of the tree.

I think future work may show if the much discredited mycoplasm theory of Eriksson will be explained by the discovery of hereditary (seed-borne) symbiosis in many plants where a perennial mycelium can be detected within the tegmen of the seeds.

Details of this work, with experimental observations, will be published elsewhere.

ELECTROSTATIC HAZARDS IN INDUSTRY

THE Institution of the Rubber Industry organised a forum to discuss "Electrostatic Hazards in Industry" on December 9 at the James Watt Memorial Institute, Birmingham. Mr. W. E. Madge (Dunlop Rubber Company) was in the chair, and the proceedings opened with five short papers each dealing with a particular aspect of the electrostatic hazard.

Mr. S. H. Wilkes (H.M. Senior Chemical Inspector of Factories), in his introductory remarks, dealt with the general principles to be borne in mind when considering electrification of materials and the consequent fire or explosion hazard. Inflammable materials—vapour, gas, or finely divided suspensions of dust—ignite only when the concentration lies within certain limits. Within this inflammability range, ignition may be caused by a rise in temperature of only a part of the system or by an electrostatic discharge. The obvious steps to take in minimizing the probability of ignition include the control of concentration and the elimination of the igniting source. Mr. Wilkes emphasized that the former must be considered of first importance; the elimination of explosive concentrations is more easily achieved in practice than the removal of all possible sources of ignition. At the same time, all reasonable steps must be taken to eliminate the occurrence of dangerous amounts of static by earthing securely all conductors, and by installing conductors instead of non-conductors wherever this is practicable.

Dr. F. J. Llewellyn (University of Birmingham) underlined the need for comprehensive laboratory data concerning the electrification and electrostatic ignitibility of substances likely to be met with in industry. Dealing with the theoretical side of ignition of dust clouds by means of electrostatic discharges, he mentioned a possible correlation between the energy stored in a condenser, the rate of dissipation, the voltage-time and current-time characteristics of the resulting air discharge and its incendivity. Discharge from a 0·01 mfd. condenser when no resistance, other than the leads and the spark gap, is included in the circuit produces an oscillatory current in the gap. The inclusion of a small resistance, say 500 ohms, completely removes this oscillatory nature; at the commencement of the spark, the current rises steeply to a high value, thereafter falling exponentially with time; the voltage meanwhile drops at the commencement of the spark to a low value and remains fairly constant until the spark ceases. The duration of the spark becomes progressively larger as this resistance increases, and the proportion of the condenser energy liberated in the spark rises to a maximum of about 30 per cent at 50,000 ohms, thereafter falling with increasing resistance. The ignition of dust clouds is most easily accomplished with sparks of short duration and high energy, that is, those obtained by discharging a condenser through a resistance of the order of 50,000 ohms.

Mr. G. Morris (Imperial Chemical Industries, Ltd., Explosives Division) discussed the electrification of powders in free-fall under gravity (Morris, *Proc. Phys. Soc.*, **51**, 1010; 1939) and also the ignition of heaps of powder by electrostatic sparks. The criterion of ignition is the energy stored in the condenser ($\frac{1}{2}CV^2$), and for small condensers is independent of the capacity. In laying down safety conditions for dealing with explosive powders, Mr. Morris found that 0·05 times the 50 per cent ignition energy gave a reasonably satisfactory upper limit for permissible electrification.

Mr. Fordham Cooper (H.M. Electrical Inspector of Factories) spoke of the causes of electrification in liquids during handling and movement. The boundary of an electrolyte such as water is normally highly polarized, having an electrical double layer, the inner and outer sides of the skin being oppositely charged. Anything which disturbs this surface will upset the electrical balance, with resultant separation of the positive and negative charges. Normally, any charges produced by the disturbance of a liquid will disappear by conduction if the specific resistance is less than 10^{10}–10^{12} ohms. The electrification of non-electrolytes presents a difficult problem; the probable explanation lies in the existence of traces of ionic or colloidal material in the liquid. Thus polar liquids such as alcohol or nitrobenzene are particularly susceptible to electrification. Mr. Cooper dealt also with the implication of stirring, and the addition of soaps; and suggested the following as precautions against fire and explosion: (*a*) increase conductivity of solvents; (*b*) use high flash point solvents; (*c*) earth all metal work, bonding discharging to receiving vessels; (*d*) keep up the air humidity; (*e*) do not introduce earthed or even unearthed conductors near the free surface of a liquid.

Mr. D. Bulgin (Research Division, Dunlop Rubber Co., Ltd., Birmingham) discussed the special electrostatic problems associated with rubber. Since the specific resistance of rubber lies between 10^9 and 10^{16} ohms, the leak-away time of static charges is very great; discharge may proceed either as a series of feeble sparks or as a brush. Whereas this direct discharge is usually of insufficient energy to cause ignition of inflammable vapours, induced charges on nearby conductors can become a serious hazard. Mr. Bulgin outlined the various methods available for minimizing this risk, both in the production of rubber goods and in their utilization. He described also a valve-voltmeter which he has designed (*J. Sci. Instr.* **22**, 8; 1945) which is extremely valuable in detecting the build-up of electrostatic voltages and in surveying rapidly the electrification produced at various stages in the processing of a material.

The five papers will be fully published elsewhere in due course.

CENTENARY OF KING'S COLLEGE (LONDON) ENGINEERING SOCIETY

THE Engineering Society of King's College, London, celebrated the centenary of its foundation during March 5–8. It is thus one of the oldest institutions of its kind in Great Britain, for its first meeting was preceded by only six days by the inauguration of the Institution of Mechanical Engineers. The oldest engineering institution in Great Britain, the Civil Engineers, was formed in 1818 and received its Royal Charter in 1828; the Société des Ingénieurs Civils de France was not formed until 1848.

The celebrations opened on March 5 with a thanksgiving service in the College chapel, conducted by the chaplain, the Rev. S. H. Evans, which was addressed by the Very Rev. W. R. Matthews, Dean of St. Paul's, himself a fellow of the College. This was followed by an address "King's College Engineering Society 1847–1947", delivered by Prof. S. J. Davies in the Great Hall.

Prof. Davies began by reading the resolution passed by the eleven original members on February 2, 1847: "Resolved that a Society be formed under the sanction of the Principal and with the patronage of the Professors of King's College, London, to be called the King's College Engineering Society, and that its object be to take in the various scientific and engineering periodicals of the day and that it be hereafter extended to the reading of original papers, giving prizes . . ."

By the end of 1847 nine papers, on subjects ranging from the Niagara Falls to the solution of algebraic equations, and from daguerreotype to coal gas, had been read. The practice of electing every term a committee and officers from the students was also established.

It is interesting to note that both Prof. Wheatstone, well known for his work on electric communications, and who held the chair of experimental philosophy, and Prof. Daniell, known by his hygrometer and the Daniell cell, who held the chair of chemistry, were among the early teachers in the Department. The subjects taken covered the very wide range of engineering, applied science and architecture. The development of the undergraduate studies has been towards specialization in civil, electrical and mechanical engineering, architecture being discontinued in 1912 and metallurgy in 1918.

There has been a remarkable continuity in the progress of the Society. Apart from the First World War, there have been only two short interruptions. The first was when a Mr. Gilbert moved an amendment, to a proposition dissolving the Society, to form a "Shakespearian and Dramatic Society". This was none other than W. S. Gilbert, of Gilbert and Sullivan fame. This break lasted only two years, however, and the Society was restored to health.

As stated before, one of the objects of the Society is to provide an opportunity for members to read papers of engineering and allied interest. In the last hundred years, more than 1,100 papers have been read, an average of eleven a year. The practice of awarding prizes for papers was instituted in 1871, and it has been the practice to award two prizes every year since. A third prize, to commemorate the services to the Society of the late Prof. Ernest Wilson, to be awarded for the year's best paper, was established in 1932.

Many former students and members of the Society have risen to eminence in their profession; of eighty-two presidents of the Institution of Civil Engineers, ten have been King's 'engineers'. There have been occasions when King's 'engineers' have achieved fame in other fields; W. S. Gilbert and C. K. Bird, or "Fougasse", of *Punch*, are notable examples.

In concluding his history of the Society, Prof. Davies mentioned the *King's Engineer*, which has been published annually under the joint auspices of the Society and of the Engineering Branch of the Old Students' Association.

Prof. Davies ended his address with some remarks on engineering training in general. In particular, he compared the size of technical schools in Britain with those in Germany; he believes that better results are obtained when the engineering faculty continues as a numerically small unit within the larger body of a college.

DEW IN PALESTINE

AN account has been received from Mr. S. Duvdevani, of the Palestine Meteorological Service, of an optical method of estimation of dew which he has developed at the Dew Research Station, Pardess Hanna Agricultural School, Karkur, Palestine. The need was felt for a much quicker and less costly method than that of direct weighing of the dew collected on a standard surface, so that a network of voluntary observing stations could be organised for a country-wide study of the amount of dew in the different seasons. In a dry climate such as that of Palestine, the success of certain crops is largely dependent upon the amount of dew, and the justification for measurements with apparatus not likely to give a high degree of accuracy, in which the personal factor may be rather prominent, is obvious. Agriculturists clearly wish to know primarily where the regions of most abundant dew at the seasons when this is most important are to be found. They care comparatively little about small errors in the absolute values of the figures for the amount of dew.

The optical method arrived at after ten years of study consists in exposing a standard wooden block, called the dew-gauge, at a standard height in the open, from sunset to sunrise. Dew is estimated by reference to a standard atlas of photographs, with which the size, form and distribution of the drops on the gauge is compared. Calibration was based on a preliminary study of the measured weights of dew for various types of drop distribution recorded on life-size photographs of the gauge, a selection of which is doubtless reproduced in the atlas.

A specimen Quarterly Dew Statement published by the Palestine Meteorological Service shows that in 1946 the totals for June varied more than those for April, ranging from about 7 mm. at Ramot Ha Shavim to practically nil at Jericho. If the year was not a very unusual one meteorologically, the conclusion to be reached is that, in the Rift Valley, crops get very little assistance from dew between April and June, even when there are many clear nights, and that coastal and hill country get dew on a scale unknown in the cloudy climate of England.

E. V. NEWNHAM

FORTHCOMING EVENTS

Other entries for April 14—April 19 will be found in the issue of *Nature* dated April 5

Tuesday, April 15

ROYAL STATISTICAL SOCIETY, NORTH-EASTERN GROUP of the INDUSTRIAL APPLICATIONS SECTION (at Lemington Glass Works, Ltd., Lemington-on-Tyne), at 7 p.m.—"The Application of Statistical Control to the Quality of Blown Glass-ware".

ROYAL STATISTICAL SOCIETY, BIRMINGHAM AND DISTRICT GROUP of the INDUSTRIAL APPLICATIONS SECTION (in the Chamber of Commerce, 95 New Street, Birmingham), at 6.30 p.m.—Discussion on "Standardisation".

Friday, April 18

ROYAL INSTITUTE OF CHEMISTRY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 3.15 p.m.—Prof. H. J. Emeléus: "Some Aspects of Nuclear Chemistry"; at 5.15 p.m.—Annual General Meeting.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT IN STATISTICAL RESEARCH—The Secretary of the Faculty of Economics and Politics, Marshall Library, Downing Street, Cambridge (April 19).

LECTURER IN MATHEMATICS—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (April 25).

LECTURER IN SOCIAL SCIENCE—The Registrar, University College of Swansea, Singleton Park, Swansea (April 26).

TECHNICAL ASSISTANT (temporary) in the Farm Economics Branch of the Department of Agriculture for Scotland—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 572, York House, Kingsway, London, W.C.2, quoting No. G.96/47A (April 30).

LECTURER IN THE ECONOMICS OF COLONIAL AGRICULTURE, with special reference to co-operation, marketing and credit—The Registrar, The University, Oxford (April 30).

DIRECTOR OF PHYSICAL RESEARCH in the Admiralty—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1853 (May 8).

READERSHIP IN CHEMICAL PATHOLOGY tenable at St. Thomas's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 14).

SIR T. D. OWEN PROFESSOR OF ELECTRICAL ENGINEERING—The Secretary and Registrar, University College of North Wales, Bangor (May 17).

CHAIR OF BOTANY—The Registrar, University College, Leicester (May 17).

CHAIR OF CHEMISTRY tenable at King's College of Household and Social Science—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 21).

READERSHIP IN CHEMICAL PHYSIOLOGY tenable at the Royal Free Hospital School of Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 29).

BETTY BROOKES RESEARCH FELLOWSHIP—The Whitley Professor of Biochemistry, University Museum, Oxford (May 31).

DRAUGHTSMAN in the Survey Branch, Tithe Redemption Commission—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 1843 (May 31).

LECTURER IN BIOCHEMISTRY—The Professor of Biochemistry, University of Alberta, Edmonton, Alberta, Canada (May 31).

OLIVER GATTY STUDENTSHIP for the encouragement of research in the application of physical methods to biological problems—The Registrary, University Registry, The Old Schools, Cambridge (June 1).

TRAVELLING FELLOWSHIP IN GEOGRAPHICAL RESEARCH—The Director and Secretary, Royal Geographical Society, Kensington Gore, London, S.W.7 (June 1).

READERSHIP IN MEDICAL PARASITOLOGY tenable at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 2).

PROFESSOR OF INDIAN HISTORY AND ARCHÆOLOGY in the University of Madras—The General Department, Office of the High Commissioner for India, India House, Aldwych, London, W.C.2 (Madras, June 16).

RITCHIE CHAIR OF ECONOMICS in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 24 Gordon Square, London, W.C.1 (June 30).

LECTURER (Grade II) and an ASSISTANT LECTURER (Grade III) IN THE DEPARTMENT OF APPLIED MATHEMATICS—The Registrar, The University, Liverpool (July 1).

GEOLOGIST to carry out general geological surveys and special hydrological and soil erosion studies—The Sudan Government Agent, London Office, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Geologist' (July 1).

UNIVERSITY LECTURER IN JAPANESE—The Secretary, Faculty Board of Oriental Languages, 167 Huntingdon Road, Cambridge (July 1).

ENGINEERING TEACHERS, both junior and senior and in various branches, by the Departments of Civil Engineering and of Mechanical Engineering—Dean J. J. O'Neill, Faculty of Engineering, McGill University, Montreal 2, Quebec, Canada.

THE SCIENTIFIC INSTRUMENT INDUSTRY

THERE have been many conflicting accounts since the conclusion of the War in regard to the condition of universities, technical institutions and other educational establishments in those European countries which either endured long periods of enemy occupation or were over-run by the tides of military operations. Nevertheless, little factual information has been available of the extent to which facilities for education in science and technology survived the six years of hostilities. It was to be expected that, in the general destruction of buildings which has taken place on the Continent of Europe, and, incidentally, in Great Britain, educational establishments would have fared no better than other classes of property. On two other counts, however, it seemed probable that the facilities for the acquiring, and the pursuit, of scientific knowledge would have emerged from the War much impoverished. It was known, in the first place, that it was a policy of German occupation forces, certainly in some European countries, to repress and even to eliminate facilities for cultural advancement. In the second place, the scientific nature of the War gave a special value to scientific equipment and, although the capacity of Germany for the production of scientific instruments was very great indeed, it appeared likely that a large-scale removal into Germany of scientific instruments and apparatus might well have occurred in order to swell the German war effort.

Preliminary information which was obtained through the activities of the Science Commission of the Conference of Allied Ministers of Education indicated that the deficiency in scientific equipment on the Continent of Europe was very great indeed, and that the volume of scientific instruments and equipment required to make good this lack would be equivalent to several years normal output of the British and American scientific instrument industries. In view of the leeway to be made up in the supply of scientific equipment to educational institutions throughout the whole world, it appeared that the problem of European rehabilitation in this respect was one for which only a very long-term solution could be found. It was felt, however, that it might not be unnatural to suppose that the requirement for scientific equipment in the European countries had been over-estimated rather than under-estimated, and from the Science Commission itself came the first suggestion that a mission of inquiry should visit the European countries to obtain first-hand information on their instrument requirements. The mission consisted of British and American personnel, and the report of the two British representatives, Mr. Thomas Martin, who was at the time of the mission deputy director of instrument production in the Ministry of Supply, and Mr. R. W. H. Cooke, of the Directorate of Medical Supplies, has recently been made available. It is a relief to learn from that report, largely written by Mr. Martin, that the task of rehabilitating the countries of Europe in respect to the scientific equipment of their educational establishments, although a very considerable one, is not so great as to be almost impossible of achievement in any reasonable period of time.

A digest by Mr. Martin of the report of the mission appears on p. 523 of this issue of *Nature*, and there would be little point in repeating facts and figures. Neither is it necessary to direct attention to the high desirability of the rapid and most complete restoration of scientific culture in Europe. It is proposed rather to deal with the implications of meeting this need of Europe for scientific instruments. It is apparent from the report that in the past Europe has, in general, looked to Germany for the supply of scientific equipment; and that, with one or two exceptions cited in the report, the activities of British instrument manufacturers were almost unknown on the Continent. It is, of course, common knowledge that Germany was, before the War, the chief country of the world for the production of scientific instruments. Without entering into the reasons for Germany occupying so predominant a position in respect to scientific instrument manufacture, or discussing the means adopted to maintain the position once it was established, it is relevant to remark that, while it would be most foolish not to admit that the average German scientific instrument was a most excellent product, there was much that was legendary in the very prevalent assumption of superiority of the German instrument over its British counterpart. It is assumed throughout the report of the mission that the European deficiency in scientific equipment would be met from British and American sources, and the exhibition of British scientific instruments recently held in Stockholm (see *Nature*, July 13, 1946, p. 66) gave a clear indication that in respect to quality the Continent was not being driven to use an inferior source of supply. Great Britain has lost much through the War, and it did appear to be a happy circumstance that the scientific instrument industry of the country, upon which the activities of scientific workers and the prosperity of industry are so largely dependent, would be considerably strengthened by the opening to it of European markets which had hitherto been largely closed.

It is therefore very disturbing to find, as is noted in the report, that the British instrument industry is still struggling with two main problems, shortage of skilled labour and inadequate factory accommodation. The shortage of skilled labour results largely from the disappearance during the war years of apprentices and improvers in the scientific instrument firms. This shortage is, of course, being felt in all branches of industry, but the impact on the instrument industry is felt in a peculiar measure, since the proportion of skilled labour in the industry is probably greater than in any other. The position is aggravated by the fact that the demands of compulsory military service make it difficult to remedy the deficiency. The productive capacity of the instrument industry was greatly enlarged during the War, and had the expansion in capacity been of a kind which could be readily maintained, it might have been that Great Britain's share in the re-equipment of European institutions for the teaching of science might have been carried out without undue difficulty. It happened, however, that the expansion of the instrument industry largely took place by the requisitioning of factories producing goods which were felt to be non-essential during the war period. These factories are now being de-requisitioned, and the instrument industry in Britain is now, in fact, a contracting one. In addition to the two main problems mentioned in the report, there is a third one, namely, the shortage of raw materials; and the dislocation in planned production resulting from uncertain delivery of raw materials not only limits the degree of production but also adds considerably to its cost.

The issue of the report, with its indication of a large requirement on the instrument industry of Great Britain for the provision of scientific instruments and apparatus in countries which formerly had other sources of supply, raises the question of the future state of the industry and of its ability to meet with smoothness the demands which will be made on it. These demands fall into three main categories. There is the provision of instruments for the teaching of science in the universities and technical institutions, and for the prosecution of research in those institutions and in other research establishments. It is probably true to say that, in the past, the man of science has not been very concerned as to where he obtained his instruments so long as he could obtain them; but there can be no question that, on the grounds of convenience and of certainty of supply in all circumstances, it is highly desirable that scientific workers in Britain should in general be equipped from British sources. In the second place, there is no greater factor in achieving high efficiency in industrial production than very complete instrumentation. For example, fuel economy can only be fully achieved through adequate instrumentation. In this competitive world, efficiency of production is essential and, therefore, in respect to an adequate export trade, inadequacy in the instrument industry may have alarming implications. Lastly the scientific instrument itself provides a mos economic article of export, since the cost of a scientific instrument rests not in the value of raw materials but almost entirely in the results of skilled labour If the industry finds difficulty in meeting the demands made upon it from the Continent of Europe, there must be foreboding as to its ability to play its vital part in the life of Great Britain in the future.

No one would wish to question the correctness of the urgency of priority given to such projects as housing; but it would be a pity, and in fact almost absurd, if the application of such priorities be made rigidly and automatically, thus preventing the instrument industry from receiving the necessary materials and facilities; for this industry must provide essential equipment required to enable science to play its full part in the rehabilitation of every phase of the national life. Indeed, the achievement of priority projects themselves may be delayed through the producing industries being denied any one of the prime means of working at full efficiency. There are implications in this report upon the needs of European countries for scientific instruments and laboratory equipment, which provide grounds for serious thought as to whether adequate consideration has been given to the maintenance of an instrument industry in Great Britain capable of meeting every demand made upon it; and whether, as stated in the preamble to the report, it is not unreasonable to ask that special consideration should be given to the post-war problems of this small but vital industry.

FIBRE PHYSICS

Contribution to the Physics of Cellulose Fibres

A Study in Sorption, Density, Refractive Power and Orientation. By P. H. Hermans. (Monographs on the Progress of Research in Holland during the War, No. 3.) Pp. xvi + 224. (Amsterdam, Brussels, London and New York: Elsevier Publishing Co. Inc., 1946.) 3.50 dollars.

THE trend of fibre research to-day is towards a clearer understanding of the parts played by the crystalline and non-crystalline fractions in determining the properties of the fibre, and this is the theme of Dr. Hermans' monograph. It may be said at once that he has chosen to consider, perhaps wisely as a beginning, those phenomena for which the properties of the fibre may reasonably be supposed to be additive with respect to the behaviour of the two fractions. The physical ideas on which he bases his discussions are of the simplest kind, and even if one feels that he sometimes tends to over-simplification, one cannot but admire his astonishing faculty of getting the most out of such elementary postulates.

At the outset Hermans admits that the partition of the fibre into two fractions is by no means absolute; as a working hypothesis, however, he interprets the term 'crystalline' in the strict sense, as giving rise to coherent diffraction of X-rays. Those cellulose chains, or parts of chains (he rejects the micellar theory in favour of the network), which are not included in the crystalline regions are assumed to combine statistically to give an average behaviour which as a first approximation is independent of the source and modification of the fibres. This dichotomy is, however, to be regarded as schematic, and is justified only if it provides a reasonable interpretation of the experimental results.

Hermans' ideas on water adsorption are best explained with reference to fibres containing 'Cellulose II', that is, regenerated and mercerized fibres. Having established the fact that the lattice dimensions of crystalline Cellulose II change with the water-content ('regain') of the fibre, he associates this with the formation of a hydrate (I) with a water content of 3·7 per cent. This hydrate is also formed in the 'amorphous' fraction, but here a second hydrate (II) (14·8 per cent water) is possible as well. The idea of hydrate II is based on the X-ray result that under suitable conditions a third cellulose modification—the so-called 'water-cellulose'—is possible. A relatively simple picture of the 'chemically bound' water is obtained in this way; it carries the adsorption isotherms up to a relative humidity of about 65 per cent. Native cellulose differs from Cellulose II in that in it only the non-crystalline fraction takes part in the sorption; the mechanism of water uptake is, however, the same in this as in the corresponding fraction of Cellulose II.

Arguing from the remarkable similarity in the shapes of the isotherms for various kinds of cellulose fibres, it is claimed that the ratio of the regains of any two fibres at any humidity will also be the ratio of the non-crystalline percentages in the fibres; regenerated fibres are thus found to contain about twice the percentage of 'amorphous' material as native fibres, whereas mercerized cellulose lies almost exactly midway between these extremes. At the lowest regains two results are noteworthy: the values of the sorption ratios of regenerated fibres relative to cotton tend to rise above their mean values, as would be expected on account of the formation of hydrate I in the crystalline Cellulose II; and the differential heat of adsorption for dry viscose is the same as for cotton, which should be so if the initial water uptake is due to the formation of the same hydrate in both fibres.

The question as to what is the correct immersion medium to use in measuring the density of textile fibres is still, apparently, unsettled. Water, organic solvents, and helium have all in turn been advocated, and until recently Hermans belonged to a school which favoured a reversion to water; but now he has taken a further step in the second cycle and prefers the organic solvents. From his point of view these score in comparison with helium because they are more likely to give different densities for fibres containing different amounts of crystalline material; and his results do, in fact, show that there is a close inverse relation between dry fibre density and sorptive power (which, of course, he has already linked up with the 'amorphous' percentage). The well-known rise in the density at low regains, formerly attributed to an increase in the density of the adsorbed water, Hermans explains simply as a geometrical packing effect of the water molecules fitting into inter-chain spaces in the non-crystalline fraction. This idea receives some support from the observed negative correlation between the dry density and the apparent density in water of regenerated and mercerized fibres; but native fibres do not fit into the scheme at all well, and Hermans concludes that it is not yet possible to give a quantitative interpretation of the observed densities in water for all cellulose fibres.

In the chapter on the optics of cellulose fibres much use is made of Gladstone and Dale's rule, which is shown to be of wide validity if applied to the *mean* refractive index of dry fibres. It is also the basis of a simple theory giving a very good quantitative interpretation of the optics of moist fibres. This assumes the additivity of the polarizations of the cellulose and water, a simplification which seems to give good results but which may not appeal to all readers. In the section devoted to the effect of orientation on the refraction one feels that had more consideration been given to other native fibres than ramie, and in particular to cotton, the sense of anticlimax engendered by Hermans' final admission that native and regenerated fibres cannot be included in the same simple scheme would have been avoided.

The last chapter is devoted to crystallite orientation, and here we may only note that as a result of his analysis of the 'optical' and 'crystallographic' orientation factors Hermans is able to set a limit, not as yet very accurately, to the value of the 'crystalline/amorphous' ratio. In regenerated fibres not more than one third of the fibre substance can be crystalline.

No mention of Hermans' work would be complete without a reference to his admirable experimental techniques, which are described in considerable detail in a series of appendixes. Altogether we must congratulate Hermans on his stimulating account of these researches carried out under conditions which at best could not have been very encouraging.

H. J. Woods

MAMMALIAN REPRODUCTION

Patterns of Mammalian Reproduction

By Prof. S. A. Asdell. Pp. xiii + 437 + 12 plates. (Ithaca, N.Y.: Comstock Publishing Co., Inc.; London: Constable and Co., Ltd., 1946.) 5 dollars; 27*s.* 6*d.* net.

REPRODUCTION is a branch of biology in which the methods of the naturalist and the anatomist have contributed considerably to an understanding of basic physiological processes. The comparative study of breeding seasons has given valuable clues to environmental and other factors which condition their variation. Differences in the characteristics of the œstrous cycle, and in the manner of ovulation, have directed attention to mechanisms that underlie the overt anatomical and behavioural changes in the reproductive rhythm. In its turn, anatomical and embryological study has provided useful indications for the experimental elucidation of such problems as the differential sensitivity of tissues to hormone stimulation. To-day, however, the broad zoological basis of the subject sometimes tends to become obscured by the more rapidly growing biochemical and physiological literature, and there is a danger lest a declining interest in systematic zoological study robs endocrinology of some potential points of advance.

The value of the comparative approach to the study of reproduction is admirably brought out in Prof. Asdell's "Patterns of Mammalian Reproduction". In it he has assembled, from the literature of natural history, zoology and physiology, such information as is worth recording about the sexual physiology of mammals. About two hundred species are dealt with in the text, while information relating to some seven hundred more is pulled together in the form of tables. The domestic mammals, and those most commonly used in laboratory work, are treated in detail. In the case of the rat, for example, Prof. Asdell has in effect produced a review of practically all that is known about the reproductive physiology of the species—including a detailed statement about the histology of the reproductive organs; it runs to some twenty pages and has a separate bibliography of 150 titles. In the case of such lesser-studied mammals as the African buffalo or the flying squirrel a paragraph or two summarizes what is known about the normal mating and breeding seasons, and about any special characteristics of the reproductive system. The tabulated material gives such information as exists about breeding season, number of young and duration of gestation in the species about which least is known. All this material is preceded by an introductory chapter which provides a general summary of such matters as sex-determination and differentiation; the hormones concerned in reproduction; the underlying pattern of, and changes in, the œstrous cycle of the reproductive organs; and pregnancy.

Prof. Asdell does not tell the reader which scheme of zoological nomenclature he has followed in his path through the Mammalia, and he provides few alternative systematic names. Little difficulty should, however, be experienced on this score by English readers with access to a modern systematic list of the kind issued by the Zoological Society of London.

In selecting his sources Prof. Asdell has wisely concentrated on the most important studies of each species, and particularly on those which emphasize the quantitative aspects of the subject. It is not improbable, as he suggests, that here and there specialists may find omissions in his record. Whether or not they do, no student of reproduction can afford to do without his new book. This will undoubtedly be the reward for what must have been a great labour of compilation, and one which, happily, helps to bring up to date the opening chapters of Dr. F. H. A. Marshall's classical study of the "Physiology of Reproduction", the last edition of which appeared in 1922.

NATURE CONSERVATION IN THE BELGIAN CONGO

Animaux protégés au Congo Belge et dans le territoire sous mandat du Ruanda-Urundi

Par S. Frechkop, en collaboration avec G. F. de Witte, J.-P. Harroy et E. Hubert. Pp. xxi+469. (Bruxelles: Institut des Parcs nationaux du Congo Belge, 1941.)

THIS work is the second edition of what is in effect a guide to the protected mammals and birds of Africa, as well as a handbook of Nature preservation in the Belgian Congo. More than two hundred pages of it are taken up, often with considerable waste of space, by the proclamations, laws and local by-laws which govern field sports, Nature conservation and national parks in Belgian territory. The remaining three hundred pages constitute a guide to the protected species of mammals and birds (and one fish), designed to provide the traveller and sportsman with a means of identification; together with brief notes on distribution, habitat and habits. Much detailed and more technical information, such as particulars of sub-species and local forms, is appended in a valuable series of footnotes. The book displays a curious formality and inelasticity of treatment. Thus, dichotomous keys are provided throughout. Since practically all the species of large herbivores are protected, the keys concerned with these groups are distinctly useful. But, when we come to the birds, only a very small, seemingly haphazardly chosen, proportion of the total avifauna is preserved, so that the keys to this group are of relatively little value.

Each species is illustrated by pen drawings, often based on photographs or taken from published pictures or papers. Apart from some notable exceptions among the mammals, they tend to be wooden and harsh, and give the book an antiquated and rather stuffy air. Some good photographs and some attempts at an ecological approach, with pictures of types of habitat, would have considerably increased the usefulness, educational value and attractiveness of the volume. Whatever the subject, the scale of each illustration is given as a fraction of the natural size—leading to some quaint results. Thus, it is reasonable to be told that the drawing of, for example, a nightjar, is two-fifths natural size, but it is singularly useless and rather comic to see beneath an illustration of a charging bull elephant the words : "Environ 1/37 de la grandeur naturelle" !

There are many other minor points that might justifiably be criticized, but equally it would be unjust to lose sight of the great achievement in enlightened Nature preservation that the volume represents. British zoologists will indeed have reason for satisfaction when the British Colonial Office shows even a small part of the intelligent enterprise and enthusiasm for Nature conservation which has so long been manifest by the Belgian Government ; and when we realize that this volume bears the date '1941' it is not easy to find words to express our admiration. W. H. THORPE

ASTRONOMY AND HUMAN THOUGHT

The Stars and the Mind

A Study of the Impact of Astronomical Development on Human Thought. By Dr. Martin Davidson. Pp. x+210+8 plates. (London : Watts and Co., Ltd., 1947.) 10*s*. 6*d*. net.

IN this book the author discusses the effect of astronomical developments on human beliefs, and in addition gives an outline of the history of the science from the earliest times to the present day. The latter occupies about two thirds of the work and constitutes a valuable and comprehensive survey, illustrated by interesting plates and several diagrams.

In the opening chapters, an estimate is made of the worth of the Chinese, Chaldean and Egyptian contributions to astronomy. A short chapter on the uncertainty of the subject of Hindu astronomy is followed by a full appreciation of the Greek thinkers and their measurements, including the compendium known as Ptolemy's "Almagest". Throughout the historical survey, the impact of ideas on human beliefs is not overlooked, and in particular two chapters are devoted to Hebrew astronomy, including the origin of the Jewish week—a mystery which at present remains inexplicable. Special attention is given to the work of Copernicus, Tycho Brahe, Kepler and Galileo. The chapter on Newton concludes with a reference to deism. "From Newton to Recent Times" covers the period from the establishment of the Royal Observatory at Greenwich in 1675 to the work of modern cosmogonists.

The remainder of the book deals in some detail with the impact of astronomical developments on the Christian faith. The author finds it hard to agree with Dr. Barnes' contention that the progress of science has not forced us to admit any mistakes in Christ's views of God or of man's relation to God. Dr. Davidson directs attention to the influence that current Jewish ideas concerning the universe had on early Christian belief concerning the imminence of the end of the world, and advocates the recasting of all theological doctrines which rest on the geocentric theory of the universe. Modern astronomy has tended to modify views of 'the Fall', and the author examines at some length Canon Peter Green's work, "The Pre-Mundane Fall". Special attention is also given to "The Beginning and End of the World", by Sir Edmund Whittaker. In view of Whittaker's argument that the law of entropy involves a 'creation', Dr. Davidson devotes a complete chapter (17) to the "Second Law of Thermodynamics and the Beginning of the Universe", in which not only Whittaker's views are discussed, but also the principle of the conservation of angular momentum, especially in relation to Jeans' tidal theory ; and further, the question is raised as to how far the second law of thermodynamics has a universal application.

A short chapter on "The Expanding Universe" is followed by one on "How the Heat and Light of the Stars are maintained", and this includes some explanation of atomic structure.

In concluding his interesting book, Dr. Davidson urges the need "to adjust our view of the processes of the universe and of the place of human destiny to a new framework of knowledge". He claims that every religion, every philosophy is based ultimately on a conception of the cosmos, and his frank statements of the implications of astronomy concerning such conceptions should stimulate both philosopher and theologian in the task of relating their beliefs to the trend of modern scientific development.

H. D. ANTHONY

JEWISH PHYSICIANS AND MEN OF SCIENCE THROUGH HISTORY

Jewish Luminaries in Medical History

By Prof. Harry Friedenwald. And a Catalogue of Works bearing on the Subject of the Jews and Medicine from the Private Library of Harry Friedenwald. Pp. viii+199. (Baltimore, Md.: Johns Hopkins Press, 1946.) 3 dollars.

DR. HARRY FRIEDENWALD, professor emeritus of ophthalmology in the University of Maryland, has added to his two-volume work "The Jews and Medicine" (Baltimore, 1944 ; reviewed in *Nature*, **156**, 31 ; 1945) a third volume entitled "Jewish Luminaries in Medical History".

This volume, equal to the former publication in beauty and accomplishment of production, embodies an address containing new material on Donnolo, Maimonides, Amatus Lusitanus and others, down to Moritz Schiff and Paul Ehrlich. It refers to the wide contribution made by the Jewish medieval physicians to astronomy, notably to Mashallah (770–820), whose "Astrolabe" formed the source of Chaucer's treatise, to the Jewish physicians who were commissioned in the thirteenth century by King Alfonsus X to compile the "Alfonsine Tables", and to Zacutus the Elder, who, at the end of the fifteenth century, wrote his "Almanach", a copy of which was carried on his voyages by Columbus. An astrolabe made by Zacutus was put to practical use by Vasco da Gama. Bonet de Lattes, physician to several popes, published in 1493 a description of his astronomical ring-dial. Friedenwald's essay is followed by a catalogue of the author's unique collection of books bearing upon the subject of "The Jews and Medicine". The collection was started by his father in 1858 ; it consists of (*a*) the writings of individual physicians and publications concerning them, and (*b*) the more general works of reference.

The catalogue, replete with biographical and bibliographical detail, forms an indispensable source for the historian of science and medicine. W. PAGEL

Earth, Moon and Planets

By Fred L. Whipple. (Harvard Books on Astronomy.) Pp. vii+293. (London: J. and A. Churchill, Ltd., 1946.) 18*s*.

THIS is one of a series of books from Harvard Observatory, all of which are compiled by specialists in their own particular sphere. The present volume gives up-to-date information about the bodies in the solar system, and as it is written in language which is almost entirely free from technicalities, it will appeal to a wide circle of readers. The author devotes some space to a consideration of origins and evolution, especially to the origin of lunar craters and to the origin of the planetary system. He favours the volcanic theory of the formation of craters on the moon, but admits that meteors may be responsible for the more recent craters—those with ray systems and some of the whiter ones, and also for many of the craterlets and crater pits. In dealing with the origin and evolution of the planets in Chapter 14, he examines the arguments for and against the planetesimal hypothesis of Chamberlin and Moulton and the tidal theory, and gives his opinion in favour of a fairly rapid condensation as more probable than an accretion; but he admits that the choice between the two processes is not conclusive as the problems are complex.

A most valuable feature of the book is the planet finder and the star chart by means of which the positions of the planets can be located up to 1970. This portion will prove most helpful to many readers who want to know the positions of the planets from month to month.

The book is well illustrated by 140 figures, more than half of which are photographs.

Some minor corrections should be made in the next edition. It is usual now to accept the Astronomer Royal's recent determination of the solar parallax and to adopt 93,005,000 miles, not 92,870,000 miles (p. 3), as the astronomical unit. Although the 1931 approach of Eros is mentioned on p. 48, Hinks's value for the solar parallax is given. The extra motion of the perihelion of Mercury's orbit is more nearly 43″ per century than "about 50″" (p. 28). The velocity of escape from the solar system (presumably at the distance of an astronomical unit from the sun) is not 45 but 26 miles per second (p. 78). Further, meteors do not move with velocities of 45 miles per second relative to the sun (p. 78); this is their maximum velocity relative to the earth.

M. DAVIDSON

Statistical Analysis in Biology

By Dr. K. Mather. Second edition, revised and enlarged. Pp. iv + 268. (London: Methuen and Co. Ltd., 1946.) 16*s*. net.

THE profound effect which R. A. Fisher has had on the interpretation of biological data has been mediated through a book which most biologists can only dimly understand at first. The meanings of the new ideas put forward in this book are often not fully explained; but the interested reader is stimulated to think them out for himself. More detailed expositions of many of the new statistical methods are contained in various other books; but Dr. Mather's book is, so to speak, the authorized version. The author is primarily a biologist; but he has evidently devoted much thought to the meaning of the quantities that can be calculated from a set of data and their relation to one another. His book is illustrated with examples, and the reasoning is given at length so that much of it can be read fairly rapidly.

This book has been out of print for some time and the new edition will be welcomed. It is much the same as the first edition except that it contains a valuable new chapter dealing with two transformations which may be applied to percentages —$p = \sin^2\varphi$ and probits. In each case, the method is explained and one example is worked out.

The Bathe

An Ecstasy. By Marie Carmichael Stopes. Pp. iv + 19. (London: Alexander Moring, Ltd., 1946.) 5*s*.

OF the lyrical quality of this poem, as indeed of all Dr. Stopes' verse, there is no question. From the first apparently effortless stanza:

"Brown rocks have sucked in all the sun's warm rays
To over brimming, till they fill the air
To fine enraptured whirlpuffs gliding where
They quiver up the bank of sheltered bays",

continuing through the whole poem with the same musical consistency. Phrases slip into place with the same facility as their author appears to glide into the sea. Students of form would benefit by observing such unobtrusive craftsmanship.

"An Ecstasy" is no idle description; here is a spirit bubbling with almost youthful ebullience, whose flight is as spacious as it is melodic.

Individual lines are admirable:

"And lave my feet among these lambent pearls." "The swirl subsiding silence broods in me." "Deep clarity of blue translucence calls more than my body to be permeate."

But the author's enraptured journey tends to veil her powers of discretion. Imagination is not necessarily art.

"Soon my salt tanged palms
Vie with intoxicating scent brewed balms,
To yield sweet odours to the sun drenched sky.
Short golden hairs, minutest flagstaffs rear
Each on its tiny mound, but soon they cling
Content to nestle close like folded wing."

Avoiding this misguided sensuousness, Dr. Stopes would be a poet of quality, and a stronghold for readers who deplore the absence of buoyancy in modern poetry.

MARGARET HOWARD

Reports of the Progress of Applied Chemistry

Issued by the Society of Chemical Industry. Vol. 29, 1944. Pp. 574. (London: Society of Chemical Industry, 1946.)

THE present volume of this very useful review of the progress of industrial chemistry contains the usual sections. A notable feature is the inclusion of statistics in many cases where these had been held up during the war period. Those on coal make dismal reading. The abstracts are usually quite brief, so that it is scarcely possible to select any topics for special mention. Attention may perhaps be directed to some interesting information on moth-proofing (p. 91), on molecular weights of cellulosic materials (p. 101), plastics (p. 255), soils and fertilizers (p. 364), foods (p. 418), and fine chemicals and medicinal substances (p. 450). Many of these topics, it will be seen, are of general interest in various fields. The volume contains a very large amount of information and is well produced and indexed.

SCIENTIFIC EQUIPMENT IN EUROPE: PRESENT NEEDS

THE report has recently been issued* of a small Anglo-American mission which visited the devastated countries of Europe during the period February–June, 1946, for the purpose of finding out their needs of scientific instruments and laboratory equipment. This report has been prepared by the British members of the mission, and is based on a tour of twelve different countries. It has been made available by the Ministry of Supply for the information of those concerned, on the understanding that the opinions expressed and recommendations made are those of the authors and not of His Majesty's Government.

The countries visited, in the order named, were France, Switzerland, Italy (southern), Greece, Italy (northern), Austria, Czechoslovakia, Belgium, Holland, Denmark, Norway, Poland and Sweden. It had been intended to visit Jugoslavia, but this visit was reluctantly abandoned as the American members of the mission found it impossible to obtain visas at the time they were required. The two neutral countries, Sweden and Switzerland, were included in the tour because they are potential suppliers of some of the equipment, and also because their own needs cannot be disregarded in any assessment of European requirements.

The first suggestion of sending the mission arose at the meetings in London during the War of the Science Commission of the Conference of Allied Ministers of Education, of which the late Dr. E. F. Armstrong was chairman. Accurate information was required as to the conditions in the European countries at the end of the War. Moreover, it was considered that, in the immediate post-war period, the United States and Britain must necessarily be the principal sources of supply of the instruments and equipment needed for educational rehabilitation. The American and British Governments were therefore approached, and eventually the State Department nominated Mr. Wendell R. Turner of the Department of Commerce and Dr. James L. Thomas of the Bureau of Standards as the American representatives on the mission. The British Government appointed two officers of the Ministry of Supply, Mr. Thomas Martin, at that time deputy director of instrument production, and Mr. R. W. H. Cook. The mission was dispatched with the objects, first, of ascertaining as closely as possible the extent of the war losses of scientific instruments and laboratory equipment from universities, research laboratories and schools, and secondly, of bringing back as much information as possible as to the nature and extent of the rehabilitation requirements, to enable the instrument industries of Britain and the United States to make plans for meeting the demands. There was the incidental purpose of giving some lead to the industries of the two countries as to the export opportunities in this field, in view of the (at least temporary) elimination of Germany from the European market.

Much interesting information was obtained by the mission, and not the least valuable feature of the tour was the opportunity it afforded, soon after the end of the War, of comparing the conditions in the different countries. A separate section of the report is devoted to each country visited, and certain general considerations and conclusions in regard to the tour as a whole are set out in the introduction.

The report discloses extremely serious losses and shortages of equipment in many countries; but the opinion is expressed that there has been a tendency to exaggerate the extent of the losses as a whole. In one country, Poland, it would be difficult to exaggerate the extent of the destruction or the urgency of the need. Losses of equipment in Greece are scarcely less serious, but the problem of replacement is much smaller; while in Italy the destruction is very severe. On the other hand, certain countries actively engaged in the War have escaped relatively lightly as regards educational losses; for example, France and Norway. In all the countries, however, there are heavy arrears of normal requirements.

The value of the replacement requirements of the countries visited is estimated at not more than £18 million and not less than £14 million*. This total does not include Jugoslavia, and it was thought undesirable to include in the report any estimate for the two neutral countries, Sweden and Switzerland. Moreover, the estimates are in general based on 1939 values. When all allowances are made, however, the figure is still very much below estimates which were current before the mission left England.

Only a proportion of the total is likely to be called for from Britain and the United States in the immediate future. Some countries have considerable instrument-making resources of their own. In others there is uncertainty as to the extent of relief grants for educational rehabilitation, and as to the application of priorities in the utilization of funds or credits available. Shortage of foreign exchange is likely to limit overseas buying by most of the countries for a considerable time to come, and generally those with the greatest needs have the slenderest resources.

Intense interest in Anglo-American technical progress during the War, and a desire to fill the gaps in scientific knowledge caused by the cutting of communications during the German occupation, were everywhere manifest. In several countries sentiment was strongly in favour of obtaining scientific instruments and equipment from Britain and the United States and of breaking the previous German connexions in education and science. Resentment at German ill-treatment, for example in Holland, conduced strongly to this tendency. It must be said, however, that in the Scandinavian countries, and particularly in Norway, a different point of view was held. Many Norwegians wished to see German industry compelled to produce, and supply by way of reparations, the equipment urgently needed by the Allied countries. The dangers of a revival of the German instrument industry and of the virtual German monopoly of the Continental market were discounted or disregarded.

Whatever may be the opinions on this point, there can be no doubt that in Great Britain we have at the present time both a heavy responsibility and a remarkable opportunity in regard to the educational rehabilitation of Europe. It must be recognized, however, that in many countries very little is known of the resources of British instrument-making. There are notable exceptions: the instruments of one or two British firms are to be found in nearly every physics and chemistry laboratory in Europe; but the other makers are not well known to Continental users. In the case of survey instruments, for example, German and Swiss manufacturers have held the field so completely that the long-established and high-quality production in Great Britain is unknown. The position is very little better in regard to microscopes.

---

* Report upon the Needs of European Countries for Scientific Instruments and Laboratory Equipment. Ministry of Supply (E2), October 1946.

* The estimate of £9 million mentioned in *Nature* of January 25, p. 110, referred to a report apparently made for the United Nations Educational, Scientific and Cultural Organisation. EDITORS.

Recommendations are made in the report with the view of correcting this state of affairs, particularly the setting up of more effective agencies for the British instrument industry in the principal cities of Europe. These should be well provided with instruments as well as literature, and have adequate servicing facilities; and it is suggested that a special study should be made of the commercial peculiarities and methods of ordering in the different countries. Reference is made to the very successful exhibition of British instruments held in Stockholm in May 1946, which was highly appreciated in Sweden; and the holding of further exhibitions in other countries is strongly advocated.

As to the nature of European requirements, the following passages are best quoted in full:

"It can be said with certainty that there is no type of scientific equipment which is not wanted somewhere in Europe; but we early found that it would not be practicable to bring back anything in the nature of detailed lists with quantities attached for each country. So varied are the needs and so dependent the ordering is likely to be on local conditions and personal preferences that such statistical information is generally not available in the countries themselves. Much miscellaneous information bearing on the needs of particular institutions is however given [in the separate reports for each country].

"Apart from this there are certain general shortages to which attention must be drawn. In nearly every country of Europe there is a serious, and in some cases an acute, shortage of laboratory glassware, that is to say, beakers, flasks, funnels and test tubes, particularly in the heat-resisting varieties, as well as graduated glassware, glass tubing and rod, and glass apparatus of all kinds. There is an equal shortage of laboratory porcelain, and of miscellaneous laboratory supplies—filter papers, rubber tubing, corks and the like. In many countries too, stocks of chemical reagents are long since exhausted, and further supplies, particularly of pure reagents, cannot be obtained. It is no exaggeration to say that in many parts of Europe the experimental teaching of chemistry is at a standstill because of these shortages of consumable laboratory supplies.

"As to direct war losses, heavy equipment, while it may have been damaged, for example by the stripping of non-ferrous metal components, has often been left and is repairable; but instruments of a portable character, such as microscopes, spectroscopes, lenses and photographic equipment, balances, galvanometers, resistances and small electrical instruments of all types, have everywhere been looted. Of all such instruments, large numbers are wanted in every country.

"Another serious shortage is of metal-to-glass equipment, that is, radio valves, X-ray tubes, cathode ray oscillographs, discharge lamps, rectifiers and so forth.

"Interest in war-time technical developments, particularly radar and atomic physics, will cause a demand for new equipment in many places. We saw cyclotrons in five different countries, and heard of others building. . . . High tension plant, Wilson chambers and their accessory equipment, hydrogen and helium liquefiers, compressors and vacuum pumps will all be wanted."

A shortage which was not strictly the concern of the mission, but which was everywhere apparent, was that of scientific and technical literature, particularly British and American text-books, journals and periodicals. In every university library the gaps in the shelves for the volumes from 1939 onwards were pointed out, and many of the professors regarded this as the most serious shortage of all. The problem of the back numbers and missing text-books is so serious and so important to science that a special and concerted effort is clearly needed to ensure the printing or re-printing of the missing books.

In the reports on the separate countries the visits to universities and institutions are described, and the conferences with government and other officials are summarized. In certain countries which have suffered heavy losses, among them Belgium, Holland and Czechoslovakia, the energy and initiative with which the problems of educational reconstruction are being tackled are most impressive. In other countries the circumstances are less satisfactory, and again the report may be quoted in full:

"In our report on Poland we have indicated that the destruction and loss to the educational system is so severe, and the resources seemingly so inadequate, that the problem becomes one of a different nature from that in some other countries. Elsewhere there are conditions which are almost, if not quite as serious. It would be impossible for any person of ordinary goodwill to see the state of the institutions we visited in Warsaw, in Athens and in Naples, without wishing that some way could be found to cut through the political and economic barriers which hold up action through the official channels, and bring some direct and immediate assistance to the courageous men and women who are struggling to carry on their work in these places. . . . There are in a few countries, and particularly in a few institutions within those countries, conditions so deplorable, and prospects of relief so remote, as to suggest that there are grounds for special action to relieve the most serious cases."

As to the part the British instrument industry may be able to take in dealing with this urgent problem, it is clear that greatly accelerated production of scientific instruments and laboratory equipment is needed to relieve the shortages in Europe. On commercial as well as humanitarian grounds the production is needed, for early delivery is the important consideration if the export possibilities are to be realized which the situation in Europe presents. Copies of the report have already been put at the disposal of the Council of the Scientific Instrument Manufacturers' Association of Great Britain, which is giving active and sympathetic consideration to its recommendations; but the industry is suffering from grave handicaps at the present time, among them inadequate factory space, shortage of skilled labour, and not least, difficulty in obtaining supplies of basic raw materials. It is much to be hoped that ways and means may be found of enabling this vital industry to continue, into the post-war years of reconstruction, the magnificent effort it made during the War.

THOMAS MARTIN

PEAT, HAY-FEVER AND PHARMACOGNOSY

By Dr. T. E. WALLIS

Curator of the Museum of the Pharmaceutical Society of Great Britain

THAT three subjects so diverse as peat, hay-fever and pharmacognosy should have a common meeting-ground of fundamental importance appears somewhat surprising. The common ground is found in the morphological study of pollen. Pollen grains were first studied in detail about 250 years ago by Nehemiah Grew. On plate 58 of his "Anatomy of Plants" he gives drawings of the pollen of eleven different plants. Grew referred to pollen as the "Particles of the Attire", the "Attire" being the andrœcium of the flower. He discusses the use of pollen, noting in Book 1 of his treatise that "it is for Ornament and Distinction to us and for Food to other Animals", while in Book 2 he refers to the uses previously discussed as being the "Secondary Uses" and proceeds to say "the Primary and chief Use of the Attire is such as has respect to the Plant itself" and "that the Attire doth serve, as the Male, for the generation of the Seed"[1]. It is clear, therefore, that Grew had a good understanding of the nature and functions of pollen.

During the subsequent two hundred years little advance was made, due principally to the inadequate microscopes in use at that time. However, by the beginning of the nineteenth century much improvement had been effected in microscopes, and the study of pollen was stimulated by the publication of books in which pollen from many plants was more adequately described than had been done previously. Chief among these were: (1) the well-known treatise of Hugo von Mohl, "Über den Bau und die Formen der Pollenkörner", Bern, 1834; (2) the "Micrographic Dictionary", London, 1856, by Griffith and Henfrey, in which there is a good article on pollen illustrated by excellent figures; and (3) a book containing drawings and descriptions of 450 pollens, entitled "Pollen", by M. P. Edgworth, London, 1877. These books and the increasing popularity of the microscope as a means of entertainment in polite society led to a greatly increased interest in pollen either as being objects of great beauty or as providing a means of identifying plants or families of plants (Fig. 1).

Pollen of Peat

Following upon this period, interest began to be taken in the origin of peat, both in Switzerland, where Früh (1885) published an article entitled "Critical Contribution to the Knowledge of Pollen in Peat", and also in Sweden, where Trybom (1888) noted how resistant pollen is to decay and suggested that pollen grains might serve as index fossils in palæontology. Systematic examination of pollen in peat began about 1916 when L. von Post wrote an article upon "Certain Bogs of Southern Sweden". At the present, pollen of peat deposits is regularly examined; the spores and pollen grains are counted and identified and their percentage proportions determined. From the results a good estimate can be made of the type of vegetation present when the peat was being formed, and the relative ages of neighbouring formations can be determined. Other geological problems also can be solved[2].

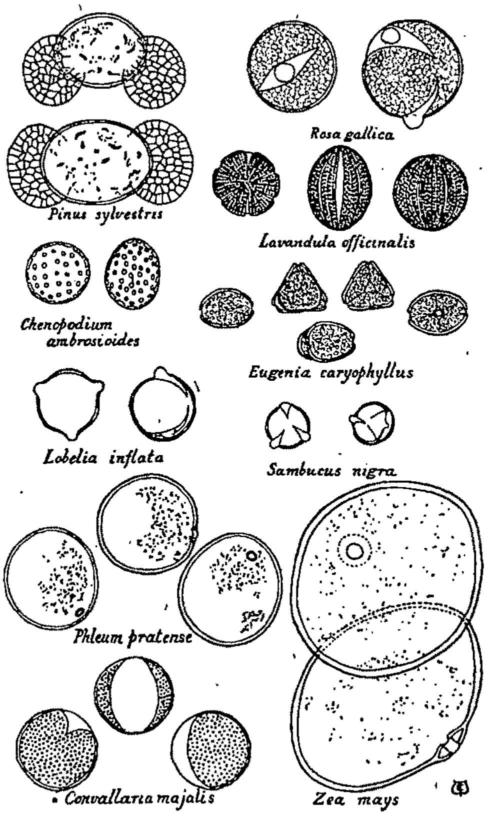

Fig. 1. POLLEN GRAINS FROM PLANTS OF ECONOMIC IMPORTANCE, SHOWING THE VARIETY OF SHAPE, SIZE AND MARKING. × c. 300

Hay-Fever

Three quarters of a century ago, C. Blackley, an English physician, living at Manchester, made experiments to discover the cause of hay-fever, and published his results in a thesis entitled "Experimental Researches on the Causes and Nature of Catarrhus Æstivus". He showed that susceptible persons quickly developed hay-fever when pollens of a large number of plants were applied to the (*a*) nares, (*b*) larynx, (*c*) conjunctivæ, (*d*) tongue and fauces. He also found that pollen of grasses was most potent, that of the common rye, *Secale cereale*, being especially toxic. He gave a list of fifteen families of plants the pollen of which produced hay-fever, and he found that in the month of June the number of air-borne pollen grains was at a maximum, 880 grains being collected on 1 sq. cm. of glass in one day[3].

From 1873 until 1916 this problem was allowed to remain as Blackley left it. In 1916, however, the investigation was revived with vigour in the United States by W. Scheppegrell, and since then it has been developed in that country by making systematic surveys of the atmospheric pollen in many of the States. The results have been collected and extended by Roger P. Wodehouse[4]. He has named a small number of families of plants, grouped in two sets, which he regards as particularly toxic in producing hay-fever; these are: (1) Herbs and Grasses—Gramineæ, Compositæ, Chenopodiaceæ, Amaranthaceæ, Plantaginaceæ, Polygonaceæ; (2) Trees and Shrubs—Betulaceæ, Fagaceæ, Ulmaceæ, Moraceæ, Juglandaceæ, Salicaceæ, Aceraceæ, Oleaceæ[5]. He concludes that the grasses possess the highest toxicity and that, since their toxicities seem to be of a similar type, it is necessary to use one pollen only for medicinal purposes, and timothy or cat's tail grass, *Phleum pratense*, is considered most suitable.

Pollen surveys were not made in Britain until quite recently, the first ones having been planned and executed at Llandough, near Cardiff, by Hyde and Williams in 1942 and 1944. Pollen was collected on microscope slides smeared with a thin coating of glycerin-jelly, and they were exposed in two ways: (1) in a horizontal plane, 'gravity slide'[6], upon which the pollen fell by gravitation from the atmosphere; and (2) in a vertical plane, kept constantly facing the wind, 'impact slide'[7]. The slides were exposed on the roof of the Llandough Hospital, supported on a stand about 12 in. above the roof-level, and were protected from rain, snow, etc., by a covering about 12 in. above them, stand and cover being about 3 ft. in diameter. At the end of the period of exposure (usually twenty-four hours) the slides were removed, a drop of glycerin-jelly applied and a cover-glass. The pollen grains under the cover-glass were identified and counted. The results were finally recorded in the form of graphs showing variations from day to day over a period of eleven months. The hours of bright sunshine for each day were recorded on the same graph so as to allow of correlation between sunshine and abundance of pollen. It was established that the effective pollen season extends from early March to late September, and that it shows three distinct phases dominated respectively by the pollen of (*a*) trees, (*b*) grasses, and (*c*) dicotyledonous herbs, the major part of the pollen being from anemophilous plants. It was also shown that periods of maximum numbers of pollen grains corresponded with periods of maximum sunshine.

For the modern treatment of hay-fever, an immunizing solution, known as a pollen-vaccine or allergen, is prepared from the pollen of *Phleum pratense* (Fig. 1) or from a mixture of pollens from a few selected grasses such as *Phleum pratense, Dactylis glomerata, Alopecurus pratensis, Anthoxanthum adoratum* and *Poa* spp.[8]. The collected pollen is extracted with ether to remove fatty matter; the residue is dried over calcium chloride or phosphorus pentoxide for several days and is stored until required. The allergen is made by macerating the prepared pollen in physiological saline, mixed with glycerin and phenol or in a special medium composed of sodium chloride 0·5 per cent, sodium bicarbonate 0·275 per cent, phenol 0·4 per cent, and water to 100[9]. The maceration is continued for about eighteen hours in a refrigerator, after which the macerate is filtered off, passed through a Seitz filter pad into a sterile filtering flask, from which it is transferred to sterile bottles for storage. When required for treatment the allergen is filled out into small sterile rubber-capped vaccine bottles. At least three different standards are used for the allergen solutions, the units being (1) representing the extract from 0·001 mgm. of pollen, equivalent to about 80–100 pollen grains and known as a Noon unit; (2) equivalent to 0·00001 mgm. of nitrogen precipitable by phosphotungstic acid; (3) equivalent to 0·02 mgm. total nitrogen per mil. The treatment extends over about three months prior to the pollen-distribution period, the allergen solution being injected subcutaneously, beginning with very small doses and ending with 5,000–10,000 units[10]. Repetition of the treatment for three years in succession is generally necessary for immunization.

Pharmacognosy

Pollen grains are used in the science of pharmacognosy as an aid to the identification of drugs and spices, more especially for determining the sources of different kinds of honey and for the identification of powdered drugs such as cloves and belladonna herb. For all these purposes, the morphology of the pollen grains must be studied and records made of diagnostic characters, such as (1) dimensions and shape, (2) surface characters of the exine, (3) presence or absence of pores and germinal furrows, (4) contents, such as fixed oil and small starch granules[11]. Using these features, pollen grains may be grouped upon a plan such as the following:

(1) No furrows and (*a*) no pores, for example, gymnosperms and *Crocus sativus*; (*b*) one pore, for example, grasses; (*c*) two pores, for example, *Colchicum*; (*d*) numerous pores, for example, *Chenopodium*.

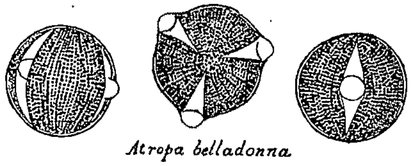
(2) One furrow, no pores, for example, *Convallaria* and many other monocotyledons.

(3) Three furrows and three pores, for example, most dicotyledons.

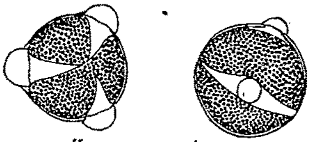
(4) Six furrows and six pores, for example, lavender and many other Labiates.

The mountant for the pollen is important because the shape and size depend upon its action. The two most useful mountants are solution of chloral hydrate (five of chloral hydrate in two of water) and lactophenol[12,13], both of which affect the pollen in approximately the same way. Chloral is used because it is the mountant in which powdered vegetable materials are most commonly examined; lactophenol is useful because it rapidly penetrates among small particles, thus avoiding heating to remove air-bubbles, and does not evaporate. Permanent mounts are generally made by removing excess of the fluid mountant and substituting glycerin-jelly.

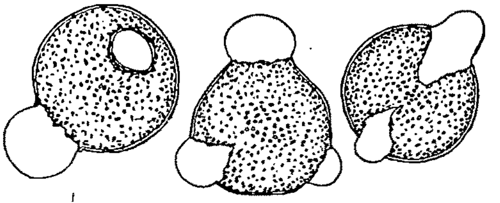
For the purpose of judging the quality and source of honey, pollen has been systematically studied in Germany by Prof. Enoch Zander, who has published



Atropa belladonna



Hyoscyamus niger



Datura stramonium

Fig. 2. POLLEN GRAINS FROM PLANTS OF THE FAMILY SOLANACEÆ. × *c*. 300

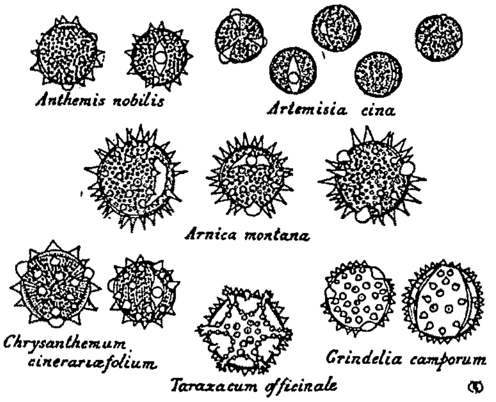


Fig. 3. POLLEN GRAINS FROM PLANTS OF THE FAMILY COMPOSITÆ. × c. 300

descriptions, including measurements, of a large number of pollens, with eighty plates of excellent photomicrographs of some 750 different kinds[13]. The pollen is separated by mixing the honey with water and centrifuging, after which the pollen is mounted in glycerin-jelly. The pollen grains are then identified and counted and a percentage table is constructed; from this a conclusion may be made as to the source of the honey[15].

Although the dimensions of pollen grains are important characters, it is probable that the shapes and markings are more reliable criteria for diagnosis. These facts are immediately evident when one examines the pollen from closely related plants. For example, pollens from the three common drugs belonging to the Solanaceæ (Fig. 2) have the following characters[14]: *Atropa belladonna*, sub-spherical, 37–50 μ in diameter, exine with lines of pits radiating from the poles, three furrows, three pores which are about 8 μ in diameter; *Hyoscyamus niger*, sub-spherical, 40–50 μ in diameter, exine with pits in a scattered arrangement, three furrows, three pores which are about 15 μ in diameter; *Datura stramonium*, sub-spherical, 56–80 μ in diameter, exine coarsely granular, no furrows, three pores which are 15–24 μ in diameter.

Similarly with pollen of compositous plants, the important distinguishing features are the presence or absence of cuticular spines, the length and number of the spines when present, the arrangement of any ridges as in *Taraxacum officinale* and other plants of the Cichorieæ (Fig. 3, and the accompanying table[14]):

Name	Shape	Diameter	Surface	Furrows	Pores	Notes
Artemisia cina	Sub-spherical	20 to 25 μ	Finely granular	3	3	No spines
Grindelia camporum	Sub-spherical	32 to 45 μ	Smooth; spines 2 μ long	3	3	21 spines in the disk
Arnica montana	Sub-spherical	40 to 52 μ	Very finely granular; spines 8 μ long	3	3	16 to 18 spines in the disk
Anthemis nobilis	Sub-spherical	30 to 36 μ	Finely warty; spines 3 μ long	3	3	12 to 13 spines in the disk
Chrysanthemum cinerariæfolium	Sub-spherical	34 to 40 μ	Lines of warts radiating from the poles; spines 4 μ long	3	3	10 to 11 spines in the disk
Taraxacum officinale	Hexagonal-spherical	32 to 40μ	Smooth spines 2 μ long	0	3	40 spines in the disk, etc.

The spores of *Lycopodium clavatum*, which are used as a dusting powder, as a vehicle for snuffs or insufflations of penicillin and menthol and also in large quantities in pyrotechnics, have an important use in microscopy to enable one to estimate the weights of materials seen in the field of the microscope[16]. The determinations depend upon counting methods based upon the number of lycopodium spores per mgm., which is 94,000[17]. This process is possible because lycopodium spores are very uniform in size, easily identified by their shape and markings and are highly resistant to most common mountants and microscopical reagents.

The study of pollen and spores has therefore yielded details of great economic importance. In addition to the elucidation of academic problems, the study has proved of much value to the advance of medicine and to the analyses of peat, honey, drugs, spices and foods, thus providing the foundation for much knowledge of such diverse subjects as peat, hay-fever and pharmacognosy.

PROGRESS OF CANCER RESEARCH

By Dr. I. HIEGER

Chester Beatty Research Institute, Royal Cancer Hospital (Free), London

THE British Empire Cancer Campaign has awarded the Garton Medal and Prize of £500 to Prof. E. L. Kennaway in recognition of his outstanding contributions to cancer research. Eighteen years after his discovery of the first carcinogenic hydrocarbon (1 : 2 : 5 : 6-dibenzanthracene), investigators are still synthesizing and testing new carcinogenic compounds although these now number more than three hundred; and in fact studies of carcinogens and their mode of action form the largest single group of investigations in progress in the twenty-one centres of research financed, assisted and co-ordinated by the Campaign.

In the accompanying table, the reviewer has attempted a classification of the investigations described in the twenty-third annual report issued by the Campaign approximately according to their numerical occurrence, but of course this arrangement is no conclusive proof of priority in any sense. Numerous modifying factors should be taken into account in any more precise evaluation. For example, some of the reports of researches are detailed, some highly summarized; some pursued by a single worker, others by a team; one may represent a project barely begun, another may be one of those long-term investigations which can only give results after several years and where, consequently, one year's report reads much the same as that of the previous year; and finally, the type of research which can take advantage of the fertile technique of organic chemistry is bound to attract more attention than others which depend upon less well-developed techniques. Nevertheless, it is obvious that carcinogenesis by chemical compounds, work on X-rays and radium, and chemotherapy form the largest three groups of investigation.

Carcinogens, their mode of action, factors affecting carcinogenesis, metabolites, carcinogenesis by tar and petroleum	15
Radiology, developments in the use of X-rays and radium, action of radiation on tissues and tissue constituents. Biophysics, use of radioactive isotopes	14
Chemotherapy by stilbene derivatives, œstrogens, urethane and other compounds	7
Filterable tumours	5
Cytology	3
In vitro culture	2
Nucleoproteins	2
Histology	1
Social distribution of cancer	1
Genetics	1
Enzymes	1
Transmissible milk factor for mammary cancer in the mouse	1

Apart from laboratory experiments, much clinical investigation has been pursued at practically all centres, and the Clinical Cancer Research Committee presents an elaborate report of nearly 1,500 cases of cancer of the rectum and anus treated statistically under thirty-five different headings dealing with the pathological, surgical and etiological aspects. Three new projects are being launched by the Campaign this year.

At Edinburgh, a pool of experimental animals is being bred, and transplantable tumours are being kept growing in animals for use by other research centres, much like the national collection of type cultures. The Campaign is producing a new journal, the *British Journal of Cancer*, and virus research in relation to cancer is to receive stimulation by a £25,000 grant, which will no doubt also accelerate experimental work with filterable tumours and in related fields such as the transmissible milk factor for mouse carcinoma, nucleoproteins, and ultra-violet microscopy.

Among the latest carcinogenic compounds to be tested at the Oxford centre are some containing sulphur; for example, 4 : 9-dimethyl-2 : 3 : 5 : 6-dibenzthiophanthrene and 4 : 7-dimethyl-2 : 3 : 5 : 6-dibenzthionaphthene. Such sulphur-containing carcinogens are no doubt already being used in tracer experiments where radioactive sulphur forms part of the molecule. At the same centre, species differences have been sought in experiments where 9 : 10-dimethyl-1 : 2-benzanthracene—to date the most powerful carcinogenic agent known—was tested on mice, rats, rabbits and guinea pigs; but it might perhaps be objected that instead of such sledge-hammer methods the test would have been more sensitive if a less active agent had been used. Some investigator with a sense of humour might try the effect of cancer-producing hydrocarbons upon the crustacean after which the disorder was named so long ago.

Bielschowsky at Sheffield is continuing experiments with one of the most remarkable carcinogens, 2-acetylaminofluorene, which when fed to rats and mice produces cancer in the liver, ductus acusticus, thyroid, blood cells, mammary gland, bladder, stomach and uterus. He has found that 2-aminoanthracene readily produces tumours of the skin in albino rats, and this compound must therefore be classed as one of the simplest carcinogens. The cellular structure of these skin tumours is usually different from that of skin tumours in mice produced by hydrocarbons, and hence different processes must be involved in carcinogenesis by the two types of agent.

Many workers in this field—probably a majority—incline to the theory that the carcinogen, before it can effect neoplasia, has first to be converted by the tissues to an active derivative, which is the true carcinogen. Proof of this theory is, however, somewhat unconvincing as yet. Indeed, what evidence is available points rather in the opposite direction, since metabolic products of the carcinogens have so far shown very little carcinogenic activity. A metabolite of 2-acetylaminofluorene isolated from rat urine, namely, 2-acetylamino-7-hydroxyfluorene, has so far proved inactive as a carcinogen; the metabolite of 3 : 4-benzpyrene, namely, 8-hydroxy-3 : 4-benzpyrene, is only very weakly carcinogenic, but if the hydroxyl group is converted to methoxy, the new compound is then strongly carcinogenic. It must be noted that to speak, as some do, of 'methylated metabolite' conveys a little ambiguity, because the methylation takes place in the test-tube, but the metabolite is generated *in vivo*. Moreover, Dickens has tested the carcinogenity of the 'methylated metabolite' from 9 : 10-dimethyl-1 : 2-benzanthracene and finds it (4′-methoxy-9 : 10-dimethyl-1 : 2-benzanthracene) inactive.

At Glasgow, Peacock and his colleagues have, among much other work, extended the study of co-carcinogens to gastric cancer. By adding one of these substances, croton oil, to the diet of rats, hyperkeratosis of the stomach, but not cancer, was produced; and even if a weak carcinogen were added to a diet containing an irritant (pepper), tumours were not found at post-mortem. No mention is made of results with a combination of croton oil and weak carcinogen added to the diet, but perhaps such tests are already in progress.

At Leeds, Orr has found that when methylcholanthrene is applied to the skin of mice of the *IF* strain (highly susceptible to skin cancer induced by hydrocarbons, but not liable to spontaneous mammary cancer), cancer of the mamma and pulmonary adenomata were found in every experimental animal. Attempts were made to breed from these mice with induced mammary cancer, to see if the disease was transmissible, unfortunately without success. Work on somewhat similar lines is being pursued at Newcastle by Pybus and Miller, who are following up the extraordinarily interesting discoveries of Strong in the United States. Strong reported that the methylcholanthrene treatment of certain inbred strains of mice induced a greatly increased tendency to carcinoma, particularly of the stomach, which was transmitted to subsequent generations without any further application of the methylcholanthrene.

Advances in radiology have been on several lines, but chiefly in developments of the complicated, but immensely important, task of assessing the distribution of dosage of X-rays and γ-rays in the body of the patient in three dimensions. By means of small condenser chambers the dosage can now be measured directly in the patient during treatment, and studies are being made of the measurement of the integral dose and of the causes of X-ray sickness. Artificial radioactive substances such as radio-sodium and radio-phosphorus are being used for tracer element experiments and for radiotherapy. At the Strangeways Laboratory, Cambridge, the action of X-rays, γ-rays and α-rays have been studied in a large variety of materials ranging from inorganic substances, through *in vitro* culture of fibroblasts, to the normal brain of mice and rabbits.

At Leeds, Rudall has examined with X-rays the crystallographic structure of the proteins in the cells of the epidermis before and after cancerization, and finds that the proteins of papilloma tissues induced in rabbits by the Shope virus differ structurally from the proteins of normal skin.

The number of compounds which have been tested for chemotherapy in cancer must now run well into the thousands, and the present situation is that Haddow finds derivatives of 4-aminostilbene the most effective against transplantable tumours in rats; œstrogens are being used for prostatic human cancer and urethane for human leukæmia. It must be noted that all three compounds are also cancer-producing agents; for example, 4-dimethylaminostilbene evokes a wide variety of tumours in the rat, and urethane produces lung adenoma in mice. Œstrogens, while only weakly carcinogenic at the site of administration, produce uterine fibromata in the guinea pig (Lipschutz) and also facilitate cancer of numerous organs and tissues in mice of strains liable to spontaneous mammary cancer (W. U. Gardener). These findings reinforce Haddow's original theory that carcinogenicity and tumour-inhibitory capacity are closely linked properties of chemical compounds, somewhat in the same way that radiations in different dosages can either produce or inhibit the growth of tumours.

Koller has continued his cytological studies of the mechanism of radiotherapy and comes to the conclusion that the success of the treatment depends largely on the indirect action of the radiation, that is, upon the still healthy tissue forming the tumour bed, rather than a lethal action upon the tumour cells directly.

At the Cancer Research Laboratories of the Hebrew University, Jerusalem, detailed studies are being made of the malignant conversion of normal fibroblasts *in vitro* by the Rous agent, and on the cytology of the different strains of rat sarcomas *in vitro*, which present a great variety of structural peculiarities, although they were obtained by the same agent, namely, benzpyrene.

Prof. and Mrs. Kennaway, continuing their examination of that treasury of information, the Registrar-General's reports on the deaths in Great Britain, have extracted the facts that cancer of the scrotum is about twenty times less common in men of the highest social class than it is in the general population. Thus hygienic habits of cleanliness, and perhaps other conditions common in the wealthiest social strata, could, if spread over society in general, greatly diminish at least one form of cancer.

Cornelia Hoch-Ligeti has been confirming earlier results showing that milk added to the diet of rats receiving butter yellow (dimethylaminoazobenzene) gives considerable protection against the formation of liver tumours. It is therefore possible that dietary deficiencies may partly account for the widespread occurrence of liver cancer in the Japanese, Chinese, Indian and allied Asiatic races, and particularly the Bantus of South Africa, all of whom have been, until recently, less well nourished than Europeans.

Hieger, after ten years work on carcinogenic substances in human tissues (first discovered by Schabad in Leningrad), concludes that: (*a*) not only liver but also lung, kidney and muscle contain these substances; (*b*) human subjects that have died of cancer *or* of other diseases contain these agents; and (*c*) that they are to be found in the cholesterol-rich fraction of the tissues and are probably sterols or closely associated compounds.

OBITUARIES

Prof. F. Paschen

PROF. F. PASCHEN died in Potsdam on February 26; he was eighty-two years old. According to his daughter, the extreme cold at the time resulted in his contracting pneumonia, from which he failed to recover.

Paschen was a giant among spectroscopists, and with his passing there closes a chapter in classical spectroscopy which included such other names as those of Lockyer, Kayser and Fowler. It is difficult to realize that fifty-five years have passed since Paschen first began his classical work on the infra-red. Since then a veritable torrent of publication came from his pen, and only ceased with his death. He covered the whole of experimental spectroscopy in a masterly manner, making a succession of important discoveries. Infra-red measurements, precision wave-length determinations, analysis of series, interpretation of hyperfine structures, were all illuminated by him.

He developed the delicate Paschen galvanometer, discovered the Paschen infra-red series in hydrogen, was senior co-discoverer of the Paschen–Back effect in magneto-optics, invented the Paschen hollow cathode discharge and so on. His masterly analysis of the complicated series in the neon spectrum is a classic. Although the analysis of series in spectra was his major interest, yet he realized the value of the hollow cathode for hyperfine structure studies and did a great deal of work in this field too.

It was my good fortune to go to Berlin to study under Paschen in 1931, and he welcomed me as his first (and last) research student from England since 1914. My most vivid recollection is of a man with a dynamic virility, a freshness of mind and a generous nature. He had a profound understanding of most of the techniques of experimental spectroscopy, and it was an inspiration to see the energetic, impulsive manner in which he worked. His eyesight was unusually keen and he missed nothing. Withal he was an engaging *raconteur*, telling his amusing stories about physicists equally well in English and German. The Zeeman pictures he obtained will be surpassed only with difficulty, and he had a fund of knowledge on the use of high-resolution interferometers. He was essentially an exact experimenter, with little use either for gadgets or for those statistical methods which attempt to extract as much as possible out of observational data. In 1931 I showed him a trivial statistical trick I had developed. His smiling comment was: "If measurements on a plate are not self-consistent, smash the plate and take another. This is far better than statistics." A rash procedure possibly, yet typical of the man, whose first aim was self-consistency and internal checking in all he attempted. Yet he was bold and adventurous in interpretation, with a masterly grasp over complexity. He had a deep respect for A. Fowler, who went to the other extreme and was hesitating and cautious. Paschen admired this caution and once remarked: "Fowler has never yet made a mistake". He confided to me that independently and simultaneously with Fowler he had arrived at the important analysis of carbon and silicon which showed the existence of multiple ionization spectra. Fowler's classic paper on this appeared first, and Paschen considered it was so much better than his work that he tore up his own manuscript. This was typical, for Paschen was the last man to take even due credit for himself, and was scrupulously just in apportioning credit and priorities to others.

Until the advent of Hitler, Paschen was president of the Physikalisch Technische Reichsanstalt; in 1933 he was dismissed by the Nazis and replaced by Stark. He had made himself highly unpopular with the Nazis by persistently purchasing considerable costly spectroscopic equipment from England, maintaining that German makers could not equal the British products. After 1933 he was permitted to use a small room in the Reichsanstalt. He strongly disliked the Nazis and their methods; but possibly his age saved him. He wrote me an open denunciatory letter in 1936, which if intercepted must surely have led him to the concentration camp. Between 1933 and 1939 his time was largely devoted to measuring old plates, and a few papers were published. In 1943 he lost all his possessions in a fire raid, but although seventy-eight years of age still kept on working, and to the last was engaged on calculations.

He had many pupils and has trained a whole generation of spectroscopists who have much to thank him for, particularly in Germany and in the United States.

S. TOLANSKY

The Right Hon. Sir Halford Mackinder, P.C.

BORN at Gainsborough on February 15, 1861, Halford John Mackinder was the son of a medical practitioner and received his school education at Epsom College, whence he proceeded to Christ Church, Oxford, becoming president of the Oxford Union in 1883.

It is not clear what turned Mackinder's attention in his student days to geography, which was then a subject unknown in the universities and despised by schools, but it was almost immediately after graduation that he planned a series of lectures under the title of "The New Geography" for the Oxford University Extension Lectures. His ideas he crystallized into a paper on "The Scope and Methods of Geography" which he read before the Royal Geographical Society in 1887. It was through the interest created in the Council of the Society that the University of Oxford appointed Mackinder in the same year to a readership in geography, the only previous holder of such a post having been Richard Hakluyt in the reign of Queen Elizabeth.

Although called to the Bar in 1886, Mackinder devoted himself to university work. He became a Student of Christ Church, Oxford, in 1892, and in the same year was appointed principal of University College, Reading, now the University of Reading.

While holding those posts he became president in 1895 of Section E (Geography) of the British Association for the Advancement of Science, and put forward a powerful plea for the formation of a university institute of geography, where might be brought together what we now call 'physical' and 'human' geography on the same platform. It is again to the credit of the University of Oxford that the School of Geography there was created in 1899.

Mackinder lived to see his great aims for the university teaching of modern geography realized by the creation of honours schools in nearly all the universities of Great Britain, and there is no doubt that the part he himself played was an extremely important one.

Although he continued as reader in geography at Oxford until 1905, in 1903 he left Reading to become director of the London School of Economics and Political Science. The School was then only eight years old, and Mackinder succeeded Prof. W. A. S. Hewins. It is well known that the School was founded by a group of Socialists headed by Mr. and Mrs. Sidney Webb and Bernard Shaw; but its founders realized the danger of allowing party political views to dominate the activities of a young institution the sphere of work of which was, and is, a dispassionate academic study of economics, politics and the social sciences generally. Mackinder was already known for his Liberal–Unionist political views (he had contested Warwick as a Liberal in 1900), and his choice as director of the School supplied a valuable balancing influence and removed once and for all what might have been a real danger.

In 1909, at the age of forty-eight, Mackinder entered his political career by standing as Unionist candidate for Hawick Burghs. Though not successful in this attempt, in the following year he was elected for the Camlachie Division of Glasgow, a seat which he retained until 1922. He relinquished his post as director of the London School of Economics in 1908 but remained as reader in geography at the School (a post he had held part-time since 1900), later as professor, until 1925, serving under Pember Reeves and Sir William (now Lord) Beveridge as successive directors.

In 1920 Mackinder took charge of a special temporary mission as British High Commissioner for South Russia, at the completion of which he was knighted. After his retirement from academic work he served as a member of the Royal Commission on Food Prices in 1925, and in the following year was made a Privy Councillor, and became chairman of the Imperial Economic Committee. He was already chairman of the Imperial Shipping Committee, a post which he held from 1920, the year of its formation, until 1945.

It is difficult to assess the whole influence of Mackinder on the development of geographical thought. Although what he initiated and taught at Oxford, Reading and London has become absorbed as an essential part of geography as it is now studied throughout the universities of Britain, his ideas were often so in advance of those of his political contemporaries that they are only now coming to be appreciated. His most famous work, "Britain and the British Seas", appeared in 1902. It is rightly described as a classic. For the first time it related the physical features of our own familiar land with the sequence of human occupation and development and with our economic interests. In lucidity of language which is used to clothe the thoughts of a clear and brilliant brain, it has never been surpassed. His masterly analysis of the factors of position is only now being appreciated in connexion with the development of world airways; his concept of regional contrasts, especially between Highland Britain and Lowland Britain, or between Metropolitan England and rural areas, is only now being recognized by the development of physical planning on a regional basis so that contrasts in needs and aims can receive adequate consideration in practice. The problems of Highland Scotland, to take an extreme example, are difficult of comprehension in Metropolitan England. Mackinder made free use of diagrammatic maps or cartograms, on which selected facts only are represented, to drive home his points—this is an art well known to geographers but still relatively unfamiliar to the public.

His deservedly popular lectures exercised a great influence on the many thousands of students who crowded to hear him. Though delivered without notes, they showed his dislike of slipshod work: they were balanced, closely reasoned and inevitably closely allied to the series of sketch maps which always adorned the walls when he was lecturing.

Although he worked steadily among his parliamentary colleagues to secure an appreciation of geographical analysis, he was still in advance of his time when he published "Democratic Ideals and Reality" in 1919. It aroused interest, but not enough; and it was left to the Nazis to prostitute geography to their ideology in the school of Geopolitik. It was only during the Second World War that this remarkable work of Mackinder's began to be appreciated. The original edition was still in print when the book was re-issued in a popular form. Most great problems of the day need analysis from economic, political, sociological, historical and geographical points of view: too often wrong conclusions are reached through the neglect of one of these points of view, and the most neglected approach is still that of the geographical. In this sense Mackinder's work has still to bear its full fruit. His outstanding contributions to geographical thought were recognized towards the close of his long life by the highest award the Royal Geographical Society has power to bestow—the Patron's Medal; and the highest award of the American Geographical Society, the Charles P. Daly Medal, was presented to him in 1944.

It is not widely known that Sir Halford was a mountaineer of the first calibre. In 1899, with the help of two Swiss guides, he was the first to ascend Mount Kenya, and it was thirty years before another climber succeeded in making what is still regarded as a very difficult ascent.

He retained his brilliant intellect until the end, inconvenienced only by increasing deafness, and only a few months before his death on March 6, 1947, he had visited his old Department at the School of Economics and discussed problems with his former colleagues and students. L. DUDLEY STAMP

Sir Ali Ibrahim Pasha, K.B.E.

THE death of Sir Ali Ibrahim Pasha, of Cairo, removes the greatest personality in the medical profession of the Middle East. Sir Ali's career was a model of what perseverance and study can do.

Born in 1880, he graduated from the Cairo School of Medicine in 1901. After holding a house appointment in the famous Kasr el Aini Hospital of Cairo, he began his career as a young assistant surgeon in the provincial hospitals of Upper Egypt. Within a few years his skill as a surgeon, his personality as a humane doctor and a very pleasant colleague made his name popular and well known in many Mudiriahs of Upper Egypt.

He was then recalled (in 1907) to take up an appointment as assistant surgeon at his old hospital, the Kasr el Aini. Again his charming personality, his diagnostic acumen and surgical skill soon made him the recognized surgeon in Cairo and later in the whole of Egypt.

He became dean of the Faculty of Medicine in 1928, and took an active part in the reorganisation of medical teaching, and in the draughting and execution of a huge programme of construction and equipment of the Departments of the Faculty and the teaching hospitals. In fact, his term of office as dean from 1928 until 1940 may be considered a period of renaissance in the history of medical education in Egypt.

Ali Pasha's activities extended far beyond the boundaries of a Faculty. He instituted and organised the Royal Egyptian Medical Association on the lines of the British Medical Association. That Association now has an imposing building of its own in Cairo, with a big ceremonial hall, a library, a museum, and it issues a medical journal.

Ali Pasha was an active member and later president of the Egyptian Red Cross Society.

He was instrumental in his short career as Minister of Health in passing through Parliament a Bill creating a Syndicate of the Medical Profession to look after the interests of the profession and to provide funds for an insurance scheme.

During the last six years Ali Pasha was rector of the Fouad I University of Cairo, when his constructive genius was again most productive and his powers of organisation were most evident.

His death at the age of sixty-six was certainly a great loss to the medical profession and to the whole of Egypt. I. S.

Major M. Connolly

MATTHEW WILLIAM KEMBLE CONNOLLY was born in Bath on February 13, 1872, the son of Vice-Admiral Matthew Connolly, R.N., and Harriet Connolly, *née* Kemble. He was educated at Haileybury and Sandhurst, and for some years led the life of the Army officer of his period. He married Muriel Vernon, of Clontarf Castle, Dublin, who, with their one son, survives him.

After retiring from the Army, Major Connolly became an unofficial scientific worker in the Department of Zoology of the British Museum. He was especially interested in the Mollusca, particularly the land and freshwater molluscs of Africa, of which he had profound knowledge and on which he was the leading authority. Many papers on this subject were published from 1910 onwards: the most important was, undoubtedly, "A Monographic Survey of South African Non-marine Mollusca" (*Ann. S. Africa Mus.*, **33**, 1–660, pls. 1–19; 1939).

In later life Connolly was badly crippled by arthritis and could walk only with difficulty. Despite this handicap, he insisted on doing everything himself; indeed, I had known him for more than twenty years before he would let me walk across Cromwell Road with him, and even then only because the fog was thick and the crossing more than usually dangerous. Inside the Museum he went from room to room, and from library to library with cheerful good humour.

Connolly joined the Malacological Society of London in 1908. Five years later, in 1913, he joined the Conchological Society, becoming its president for the session 1929–30; at the time of his death he was a vice-president. He was no narrow-minded specialist; his interests were wide, his knowledge of cookery and wines extensive. He remained in London for most, if not all, of the war years, and was among the survivors when his hotel was largely destroyed by a flying bomb. That incident affected him more than he cared to admit: soon after the end of hostilities, he began to wind up his affairs in London in order to retire to Bath. This last plan was never realized; he died in South Kensington on February 26, 1947, and is buried in the family vault at Bath.

A. T. Hopwood

NEWS and VIEWS

Sir Roy Robinson, O.B.E.

It has been announced that Sir Roy Robinson will shortly relinquish his appointment as director-general of forestry. This will not, of course, mean that he is severing his official connexion with the forest administration of Great Britain, for he will remain chairman of the Forestry Commission, a post he has occupied since 1932. Sir Roy has been a member of the Commission ever since it was set up in 1919 on the recommendation of the Acland Report, in the preparation of which he himself took an important part. The adoption of that report marked a new era in British forestry, constituting the recognition, forced by the experiences of the First World War, that the State must accept responsibility for remedying the very unsatisfactory position in the matter of forests and timber supplies, with an inadequate area of forests and a very low production per acre. For some years he was the only professionally qualified forester on the Commission.

On a recent occasion, the Society of Foresters of Great Britain met to present to Sir Roy its medal in recognition of his distinguished services to forestry, services which incidentally have not been confined to Britain, for he has also taken a very active part in all four Empire Forest Conferences, presiding over the last one, held in 1935 in South Africa. In accepting the medal, he reviewed the work accomplished by the Commission, particularly during the difficult times when it was threatened with complete stoppage, and showed how almost all the arguments used against its activities and plans had later proved wrong. The Commission's 1943 Report on Post-war Forest Policy has been acknowledged in all quarters to be a very able document, though naturally enough all its proposals do not please everyone. It has been accepted by Parliament with only minor amendments as the basis of further work; it will probably come to be known as the Robinson Report, and form a landmark second only to the Acland Report. In the latest published annual report covering the year 1944–45, the total area of plantation is shown as closely approximating half a million acres, apart from another 150,000 acres on private or local authorities' lands in respect of which grants were paid. It is indeed a great achievement for twenty-five years, but only a step on the way, for Sir Roy has set us a new target—two million acres within the next fifty years—and urges that no excuses should be accepted for reducing or postponing it.

Royal Geographical Society Awards

His Majesty the King has approved the award of the Royal Medals of the Royal Geographical Society as follows:

Founder's Medal: Brigadier Martin Hotine, director of Colonial Surveys, for his original research work in air survey, his contributions to the geodesy of Great Britain and Africa, and for his cartographic work during the Second World War; *Patron's Medal:* Colonel Daniel van der Meulen, for his exploratory journeys in the Hadhramaut in 1931 and 1939, and his contributions to the geography, archæology and ethnography of Southern Arabia.

The Council of the Society has made the following awards:

Victoria Medal: Prof. E. G. R. Taylor, emeritus professor of geography in the University of London, for her contributions to the advancement of geographical knowledge, including the study of the geographical distribution of population and industry, the promotion of a National Atlas for Britain, and her studies in the development of geographical thought; *Murchison Grant:* Mr. Gordon Manley, for his observations on the meteorology of East Greenland and his research into mountain climates and snow cover in Britain; *Back Grant:* Lieut.-Colonel Andrew Croft, for his journeys in the Arctic, especially as second-in-command of the Oxford University Expedition to Spitsbergen, 1938, and in connexion with Exercise Muskox, 1946; *Cuthbert Peek Grant*, 1946: Mr. John Wright, for his survey work on expeditions to Iceland, Spitsbergen and Ellesmere Island, and in the Sudan during the War; *Cuthbert Peek Grant*, 1947: M. André Guibaut, for his exploration of the Salween gorges, Burma, 1936–37, and of the upper Tung valley on the Chinese–Tibetan borderland, 1940; *Gill Memorial*, 1947: Commander K. St. B. Collins, for bathymetric surveys between Scotland and Iceland and in Denmark Strait under enemy attack.

United Nations Educational, Scientific and Cultural Organisation: United Kingdom Committee

Mr. George Tomlinson, Minister of Education, has appointed the following committee to consult with him, in the widest possible terms, on all matters affecting the United Nations Educational, Scientific and Cultural Organisation: Mr. Tomlinson (chairman), Sir Ronald Adam, chairman, British Council; Dr. W. P. Alexander, secretary, Association of Education Committees; Prof. P. M. S. Blackett, University of Manchester; Mr. R. S. Brownell, secretary, Ministry of Education, Northern Ireland; Mr. R. A. Butler, M.P.; Mr. R. Gould, general secretary, National Union of Teachers; Mr. D. R. Hardman, Parliamentary Secretary to the Ministry of Education; Dr. W. A. F. Hepburn (Scotland); Sir John Maud, secretary, Ministry of Education; Dr. H. W. Meikle (Scotland); Sir Philip Morris, vice-chancellor, University of Bristol; Dr. Margaret Read, head of the Colonial Department, Institute of Education, University of London; Sir Ernest Pooley, chairman, Arts Council of Great Britain; Mr. J. B. Priestley; Sir Robert Robinson, president, Royal Society; Mr. B. B. Thomas, secretary of Welsh Department, Ministry of Education; Mr. W. E. F. Ward, Colonial Office, with Mr. F. R. Cowell, assistant secretary, Ministry of Education, as secretary.

Besides this committee, nine national co-operating bodies have already been established to cover the various specialized fields of the activities of the Organisation. Their main functions are to advise the United Kingdom delegates to the conferences of the Organisation and to assist in making known and carrying out projects adopted by it. Six of these are committees covering education, arts, mass communications, libraries, museums, and social sciences. The remaining three are organisations which have undertaken the functions of co-operating bodies; they are the Royal Society, for natural sciences; the British Academy, for letters and philosophy; and the Royal Institute of British Architects, for architecture and planning.

Atomic Survey

The Atomic Scientists' Association has issued a pamphlet entitled "Atomic Survey", which is a short guide to the scientific and political problems of atomic energy. The authors are Prof. P. B. Moon, secretary of the Association (Physics Dept., The University, Birmingham), and Dr. E. H. S. Burhop, both of whom are well-known nuclear physicists, and have been engaged on the atomic bomb project. In the preface, which is contributed by Prof. R. E. Peierls, it is pointed out that the subject of atomic energy is of great topical interest and importance and that many people, quite rightly, hold strong views on the proper use of this source of power. Strong views should be based on accurate information, and although it requires an expert to understand all the technical details, it is possible to present the essential facts of atomic energy in simple language so that even the non-expert may grasp them. This the pamphlet does admirably. In its thirty-two pages, divided into fourteen brief sections, there is little, if any, information which has not already appeared elsewhere; but this is probably the first time that it has been collected together into a connected and concise form. The section headings —the elements; radioactivity and nuclear reactions; the chain reaction pile; pile problems and prospects; separation of uranium 235 from mixed uranium; the physical effects and defence against the atomic bomb; the constructive application of, and military strategic significance of, atomic energy; the British atomic energy programme; the scientist and atomic energy; the control of atomic energy; and the immediate steps to ease the tension caused by the atomic bomb—are an excellent guide to the matters discussed.

"There is not and is unlikely to be any specific defence against the atomic bomb" makes it abundantly clear, the pamphlet emphasizes, that our first major task is to solve the political problem of ensuring that atomic energy shall not be used for the obliteration of mankind. Then, and only then, can scientific men devote their energy to the intense study of nuclear behaviour; to the extension of our knowledge of a subject, which the authors state with some authority is still incomplete in spite of the spectacular advances of the last decade; and to the development of constructive applications of atomic energy.

Atomic Energy Utilization in Britain

The Atomic Energy Production headquarters of the Ministry of Supply at Risley, near Warrington, is increasing its team of design and planning engineers, to speed up the development of atomic research in Britain. Already a large technical department at Risley is planning the factories, such as the one being erected at Springfields, Lancashire, which are required for the production of fissile material. This factory, one of the war-time chemical defence plants, is being converted by the Ministry of Supply into an atomic energy centre for the manufacture of uranium metal. The processes to be carried out will consist of the refining of pitchblende concentrates, reduction to metal and the machining and finishing of uranium metal rods for atomic piles. It is hoped that building work and plant erection will be sufficiently advanced for production to begin in the late autumn. When production reaches its peak, a labour force of more than a thousand will be required, of which a number will work on continuous shifts. Most of these will be recruited locally, but it will also be necessary to bring in supervisory staff with specialized knowledge.

Gordon's Astrolabe at the Royal Scottish Museum

The executors of the late Mrs. Florence Cumming, 18, Ainslie Place, Edinburgh, have handed over to the Royal Scottish Museum an astrolabe which at one time belonged to Robert Gordon of Straloch, the famous Scottish geographer. Robert Gordon of Straloch was born in Aberdeenshire in 1580 and died in 1661. He studied at Aberdeen and Paris, to which latter city he went at the age of eighteen. When he first became interested in cartography is not known, but his later work brought him fame as one of the great map-makers of Scotland. At the request of Charles I, he prepared an atlas of Scotland, which was published at Amsterdam in 1648; and it is recorded that two years later he published in the same city a second atlas of Scotland, called "Theatrum Scotiæ", which he dedicated to Oliver Cromwell—possibly the same atlas with revised title to suit the changed circumstances. Gordon is particularly noted for his revision of Timothy Pont's maps of Scotland and Blaeu's Great Atlas of the World, published in Amsterdam in 1654, a wonderful atlas in eleven large folio volumes, of which volume six contains the maps of Scotland.

Gordon's astrolabe is an interesting and most decorative relic, typical of the European version of this ancient eastern instrument. On its edge is inscribed, "Robertus Gordonius"; the instrument was probably acquired by him before proceeding to Paris, or in Paris itself. His pride of possession can well be understood, and it would be natural that the date, 1597, should be inscribed on the newly acquired treasure. The early form of the numerals on the scales, however, would suggest that the instrument was made at least a hundred years earlier than the inscribed date. The astrolabe was the universal instrument and calculator of astronomers, astrologers, travellers, and navigators from the seventh to the eighteenth century. For over a thousand years it maintained a remarkable consistency in design, and the art of its use and construction became known in almost every civilized country. Gordon's astrolabe may be seen in the main hall of the Royal Scottish Museum, Edinburgh, where it is being temporarily shown before being incorporated in the Science Gallery collection.

Industrial Research in Scotland

THE Federation of British Industries has arranged a one-day conference to be held in the Merchant's Hall, Glasgow, on Friday, April 25. Mr. Alexander Johnston, chairman of the Scottish Regional Council of the Federation, will preside at the morning session, when Sir James Lithgow will give the opening address. Papers on research in Scotland's major industries will be read by Mr. W. Barr (on steel), Sir Wilfrid Ayre (on shipbuilding), and Mr. W. G. Marskell (on heavy engineering). The chairman of the afternoon session will be Prof. T. Alty, of the University of Glasgow, and the following five papers will be given: research as a means of providing new industries, by Dr. J. W. McDavid; chemical research for Scottish industry, by Prof. W. M. Cumming (Royal Technical College, Glasgow); Scotland's mineral raw materials, by Mr. T. H. Whitehead (Geological Survey of Great Britain); research in the light engineering industries, by Mr. J. N. Toothill; the individual Scottish firm and its application of research, by Prof. R. Hay (Royal Technical College, Glasgow). Sir Steven Bilsland, chairman of the Scottish Council, will sum up the discussion and addresses. Admission to the Conference is free, and tickets can be obtained either from the F.B.I. Scottish Office, 142, St. Vincent Street, Glasgow, C.2, or from the F.B.I. Industrial Research Secretariat, 21, Tothill Street, London, S.W.1.

Acoustics Group of the Physical Society

THE Acoustics Group of the Physical Society has been formed at an inaugural meeting held at the Royal Institute of British Architects. Mr. H. L. Kirke was in the chair and Dr. Alex Wood gave an address entitled "The Contribution of Acoustical Science to Allied Studies". The meeting was attended by some 170 persons. The principal object of the Group is to provide an opportunity for the very varied types of workers engaged on acoustical problems to meet and discuss the scientific and technical implications of their work. The officers and committee of the Group, elected at the inaugural meeting to serve for the year 1947–48, are as follows: *Chairman:* Mr. H. L. Kirke; *Vice-Chairman:* Dr. A. Wood; *Joint Secretaries:* Messrs. W. A. Allen and A. T. Pickles; *Committee:* Messrs. H. Bagenal, R. S. Dadson, Dr. C. S. Hallpike, J. McLaren, B. C. Sewell, W. West, Dr. A. B. Wood and Dr. W. Greenhouse Allt. Membership of the Group is open both to members and also to non-members of the Physical Society. It is hoped to arrange for some six meetings a year, including at least one special summer meeting, which will take the form of a symposium covering a particular aspect of acoustical investigation; reprints of papers will be circulated to members when available, and it is hoped to arrange for research panels on special topics. For further particulars application should be made to the Joint Honorary Secretaries, at the Physical Society, 1, Lowther Gardens, Prince Consort Road, London, S.W.7.

Announcements

PROF. F. J. M. STRATTON, professor of astrophysics in the University of Cambridge, and Prof. A. Dauvillier, of the École supérieure d'Électricité, have been elected *Correspondants* for the Section of Astronomy, and Prof. P. M. S. Blackett, Langworthy professor of physics in the University of Manchester, and Prof. Emile Henriot, professor of physics in the University of Brussels, have been elected *Correspondants* for th Section of General Physics, of the Paris Academ of Sciences.

THE Holweck Prize for 1947 of the Physical Societ and the Medaille Holweck of the Société Française d Physique have been awarded to Prof. E. N. da C Andrade, Quain professor of physics in the Universit of London, in recognition of his experimental investiga tions on the solid and liquid states.

MR. A. J. PHILPOT, director of the British Scientifi Instrument Research Association, has been appointe director of the Scientific Instrument Manufacturer Association of Great Britain, Ltd. He will continu as director of the Research Association, and wi work from the Association's offices at 26 Russe Square, London, W.C.1. Mr. Philpot will speak o "Scientific Instrument Manufacture and the Nation at the Northampton Polytechnic, London, E.C.1, o April 24 at 7.30 p.m.; admission is free, by tick obtainable from the Polytechnic.

DR. J. L. B. SMITH, for many years in charge organic chemistry at Rhodes University Colleg Grahamstown, has recently resigned to be appointe research professor in ichthyology in the College. D Smith is already well known for his ichthyologic researches, which included the announcement in 193 of the discovery of a living Cœlacanthid fish (se *Nature*, 143, 455; 1939). Dr. Smith has also bee awarded a research fellowship in ichthyology by th South African Council of Scientific and Industri Research.

MR. W. L. HALL has been appointed chief office of the Liaison Department of the British Non Ferrous Metals Research Association, in successio to Mr. W. C. F. Hessenberg, who has been appointe head of the Mechanical Working Division of th British Iron and Steel Research Association. M Hall graduated from the Royal School of Mines wit a first-class honours degree in 1936. After two yea experience in a steel works, he joined the researc staff of the British Non-Ferrous Metals Researc Association in 1938, working on galvanizing, stre corrosion of light alloys and the properties aluminium–magnesium alloys; he was transferred t the Liaison Department in 1944.

SIR WALLACE AKERS, a director of Imperi Chemical Industries, Ltd., will deliver the May lectu of the Institute of Metals on May 21 at 6 p.m.; h will speak on "Metallurgical Problems involved i the Generation of Useful Power from Atomic Energy" Admission is by ticket obtainable from the Institut

THE Council of the Royal Society will shortl consider the nomination of not more than thre marine biologists to visit the Roscoff Biologica Station (Finistère) during the summer month Those wishing to be considered in this connexio should communicate with the Assistant Secretar of the Royal Society, Burlington House, London W.1, not later than May 7, and should submit a brie statement of the investigation which it is propose to carry out, together with an indication of th inclusive dates of the visit.

A ONE-DAY school on atomic energy for journalist arranged by the Atomic Scientists Association wil be held in the Embryology Theatre, Universit College, Gower Street, W.C.1, on April 26, 1947 The speakers will be Prof. H. S. W. Massey, Prof M. H. L. Pryce and Prof. R. E. Peierls.

Structure of Fibrous Keratin

THE generally accepted model of the structure of keratin proposed by Astbury and Bell[1] is based first on the crystallographic data obtained from X-ray studies on *whole* wool fibre, and secondly upon the interpretation of experiments on *whole* fibre extension in water, that is, 100 per cent elongation indicates a complete unfolding of α-keratin polypeptide chains[2]. Electron microscopic studies[3] have demonstrated conclusively that the cortex of wool fibre is composed of two distinct components, fibrils and matrix, that the amorphous matrix is capable of considerable elongation, and that the sub-cellular fibril, which is the component responsible for the X-ray fibre pattern, may undergo extension considerably in excess of 100 per cent without rupture. New electron microscopical evidence throws additional doubt on the picture of molecular chains extended parallel to the fibre axis, and a revision of the structural conclusions seems now desirable.

Astbury and Street[4] early pointed out that all X-ray fibre patterns from wool have diffuse haloes superimposed. These do not correspond to disoriented fibrils; by precise microphotometry of the patterns and separation of that part comprising diffuse haloes, we have been able to show that the latter correspond to the truly amorphous part of the wool fibre, namely, the matrix, the diffraction pattern from which gives the same angular distribution of scattered intensity. Preparations of matrix, obtained by partial solution of the cortical cells by mild chemical treatments, give the same pattern also, which leads us to believe that the matrix consists simply of keratin molecules showing little tendency to order. These findings are confirmed by electron micrographs of matrix material (Fig. 1), obtained by the gold-shadowing technique of Williams and Wyckoff[5], showing an aggregate of particles (keratin molecules) of average diameter 102 A.

From shadow-length measurement, the molecules appear to be approximately isometric. Assuming the density to be the same as the bulk density and that the particles are spherical, the molecular weight is calculated to be 360,000. Moreover, the fibrils (1000–2000 A. wide) show further subdivision into proto-fibrils of fairly uniform size (100 A. wide by 2000 A. long); these appear to be the ultimate fibrous units and may correspond to the micelles postulated by Speakman[6] on the basis of other work. These protofibrils are often found twisted about the axis of the fibril, giving a rope-like appearance which may account, in part at least, for the angular dispersion of the X-ray reflexions. These two features are evident in Fig. 2.

Owing to the increase in contrast arising from the gold-shadowing, the protofibrils show a further significant structure, namely, a series of particles of uniform size along their length (Fig. 2). From a large number of measurements of the spacing of these along the protofibril, the average particle diameter is found to be 110 A., and it is concluded that these do, in fact, represent the keratin molecules (as in Fig. 1) linked together to give the uni-dimensional crystals. It is further significant that this spacing corresponds to the feather-keratin fibre period obtained by low-angle X-ray scattering, found by Bear[7] to be 95 A., and to half the porcupine quill keratin period, found by MacArthur[8] to be 198 A.

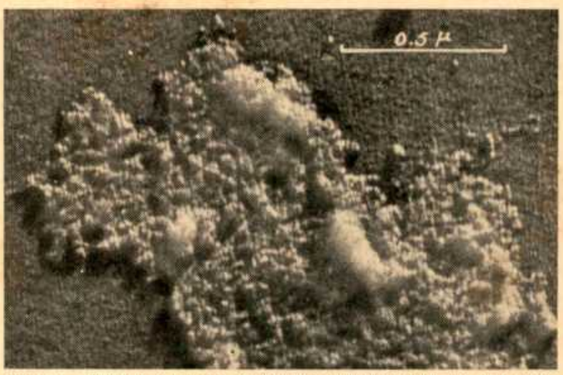

Fig. 1. GOLD-SHADOWED ELECTRON MICROGRAPHS OF KERATIN MOLECULES COMPRISING MATRIX MATERIAL FROM WOOL FIBRE. CALCULATED THICKNESS OF GOLD FILM, 9 A.

That these new features are real and not artefact is confirmed by the following. (i) They have the dimensions, within the limit of experimental error of measurement, of the particles of dispersed keratin matrix. (ii) In the background structure, usually assumed to arise from the molecules of cellulose nitrate in the supporting film, the particles have an average size of less than 90 A. This interpretation is supported by the observation by Boyer and Heidenreich[9] of such structure by direct electron microscopy (that is, without metal shadowing) of ethyl cellulose films. (iii) At fibril extremities these particles may be frequently observed in the process of splitting off the proto-fibril. (iv) The dimensions of the particles of the background vary with the nature of the supporting film (for example, polyvinyl, formal and polystyrene films show different particle sizes), whereas the spots on the fibrils remain the same.

We suggest, therefore, that the keratin molecule is a well-ordered discrete unit somewhat similar to that postulated for the globular proteins[10], and that fibrous keratin does not consist of long extended, or even partly folded, chains, but of strings of globular

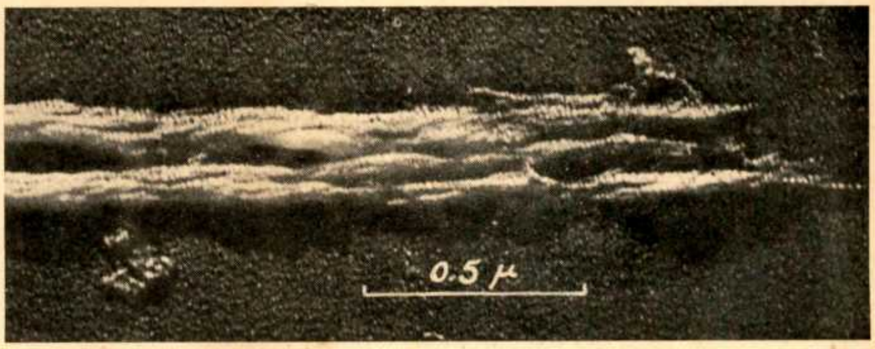

Fig. 2. GOLD-SHADOWED ELECTRON MICROGRAPHS OF FIBRILS ISOLATED FROM CORTICAL CELLS OF WOOL, INDICATING SUBDIVISION INTO PROTOFIBRILS AND SHOWING PARTICULATE STRUCTURE OF THESE. CALCULATED THICKNESS OF GOLD FILM, 9 A.

molecules. There is electron microscopical evidence that this may also be the case with other fibrous proteins[11]. Within each separate molecule the folding of the polypeptide chains must be much more extensive than the α-fold suggested by Astbury for the keratin-myosin group. This new model would not be inconsistent with the X-ray data on α-keratin. The β-keratin pattern cannot now arise from the complete unfolding of the polypeptide chain, but is more probably connected with the presence of interfold water. The importance of water in the $\alpha \rightleftharpoons \beta$ transformation has never been adequately explained by the earlier models.

A full account of this work will be published shortly.

Formation of Coking Coal by Thermal Treatment of a Cannel Coal

Geological and petrographical investigations have shown that the residues of the higher plants and the microplants (*Ölalgen*) have both played a part in coal formation: coals formed from the former have been called *humus coals*, while those from the latter are known as *sapropelite coals*. According to G. Stadnikoff[1], the vitrain of the banded bituminous coals is of mixed origin, being formed from humus and the unsaturated fatty acids of the Algæ fats. The humus coals consist of bitumens and humus, and on dry distillation give primary tars which contain phenol: the sapropelite coals (bogheads and cannels) consist of fatty acids and their transformation products, and give primary tars, rich in paraffinic and naphthenic substances, but containing no phenols.

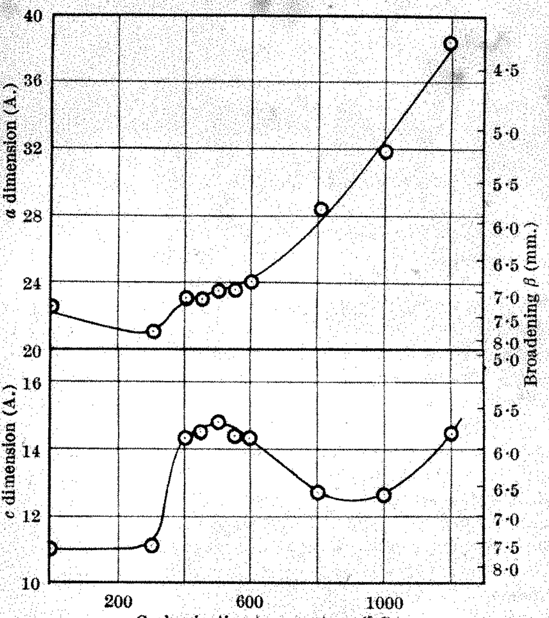

Fig. 1

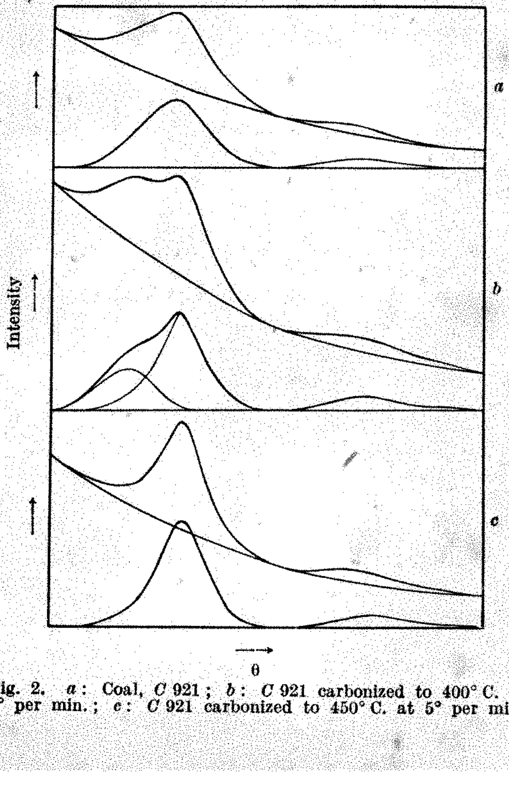

Fig. 2. *a*: Coal, *C* 921; *b*: *C* 921 carbonized to 400° C. at 5° per min.; *c*: *C* 921 carbonized to 450° C. at 5° per min.

The X-ray examination of coals[2] has shown that coking coal bitumens consist of lamellar, polynuclear aromatic molecules which contain a small but critical proportion of oxygen. The inner diffraction halo of such coals shows a characteristic variation in half-peak width when the coal is subjected to increased temperature, passing through a more or less pronounced minimum value in the neighbourhood of 500–550°. The X-ray examination of some fifty or sixty bituminous coals and lignites has shown that this behaviour is characteristic of coking coals. If the average crystallite dimension along the *c* axis (calculated from the half-peak width of the inner (002) diffraction) is plotted against carbonizing temperature, the curve obtained shows a maximum in the neighbourhood of 550°. A north Staffordshire cannel coal (C, 86·38; H, 6·65 per cent: ash, 1·26; moisture, 1·15; volatile matter (ash free, dry), 44·8 per cent), although practically non-swelling (B.S. swelling No. 1–1½) has been found to give a *c*-dimension-carbonization temperature curve (Fig. 1) with a pronounced maximum at 550°. This cannel coal was exceptional in another respect: whereas the coal itself gave a powder photograph the microphotometer trace of which showed a symmetrical inner halo (Fig. 2*a*), after heating the coal in nitrogen to 400° at 5° per min., the inner halo then showed a pronounced asymmetry (Fig. 2*b*), which no longer

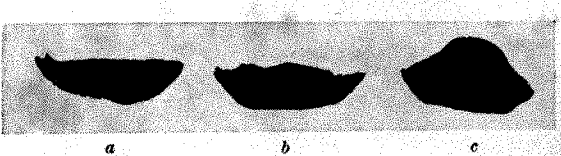

Fig. 3

appeared in the powder photograph of the coal after heating to 450° at 5° per min. (Fig. 2*c*).

A probable explanation of these phenomena is that during the heating at 5° per min., some of the naphthenic or paraffinic bitumen in the cannel escapes volatilization and undergoes aromatization, being converted into the coking coal type of bitumen. This suggests that there should be a concomitant change in caking power. Fig. 3*a* shows the coke button obtained from the cannel in the B.S. crucible swelling test, that is, by heating rapidly 1 gm. of the finely powdered coal in a silica crucible over a bunsen burner; Fig. 3*b* is a photograph of the button obtained in the same test from a sample of the cannel which had been preheated to 350° at 5° per min.; and Fig. 3*c* is of the button from the cannel preheated to 400° at 5° per min. The increase in swelling property caused by thermal pretreatment is obvious, and is made even more striking by the fact that the preheating to 400° gave an agglomerated product (loss in weight, 16 per cent) which was recrushed to a powder before carrying out the crucible swelling test.

This result has a practical significance in that the British Standards crucible swelling test, which involves rapid heating, may give misleading results if the coal under examination contains an appreciable proportion of sapropelite material. The theory that the coking coal bitumens owe their origin to the thermal decomposition of sapropelite material does not appear to be tenable in view of the fact that cannel coal sometimes occurs as one of the banded constituents of bituminous coal seams.

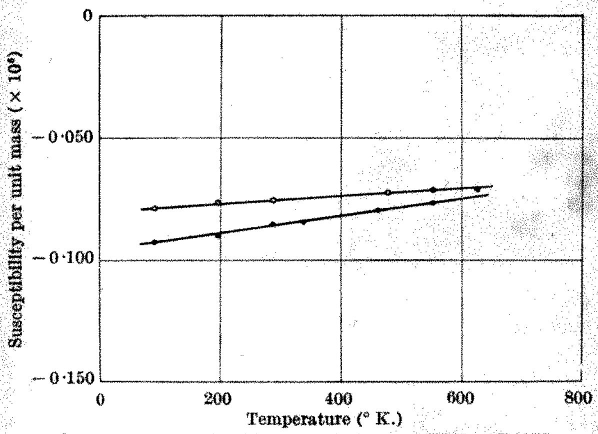
Temperature-Dependence of Magnetic Susceptibility of Annealed and Cold-worked Copper

INVESTIGATIONS recently carried out on the variation with temperature of the magnetic susceptibility of annealed and cold-worked copper have shown a different temperature-dependence in the two cases. A qualitative attempt is made to account for the difference on present theoretical lines.

The metal used was very pure 'H.S.' brand copper supplied by Johnson, Matthey and Co., Ltd., in the form of rods 15 cm. long and 5 mm. in diameter. The iron content was less than 0·005 per cent. A rod was first annealed for 10 hours in hydrogen at 950° C. and then either cooled slowly or 'quenched' in water. Both processes gave similar magnetic results, indicating that the specimens were free from ferrous impurity. In the case of the 'quenched' specimen, dissolved iron atoms should be retained in solution at room temperature, while slowly cooling the specimens should allow precipitation of the ferrous impurity.

The Gouy method and an electrodynamic balance[1] were used in the magnetic measurements. Determinations were made over the temperature range 90°–630° K. After a run had been taken with the annealed specimen, it was cold-worked by wire drawing, and its magnetic susceptibility measured over the same temperature range. Before measurement the specimen was allowed to recover for 24 hours[2]. The higher temperatures were not maintained for long periods and annealing did not take place. This was shown by the fact that the room temperature susceptibility value could be repeated afterwards.



OPEN CIRCLES, COLD-WORKED COPPER; FILLED CIRCLES, 'QUENCHED' COPPER

In the graph it is seen that the susceptibility varies linearly with temperature, the quenched specimen giving a 21 per cent change over the temperature-range as against a 12 per cent change in the case of the cold-worked specimen. Cold-working in the case shown was a 2·84 per cent reduction in diameter due to wire-drawing.

The reduction in numerical susceptibility in diamagnetic metals due to cold-working has been noted[3,4] and attributed to either of two causes: (i) change in electron orbits; (ii) precipitation of ferrous impurity[5]. It is considered in the present work that the decrease in diamagnetic susceptibility is not due to the presence of impurities. The reasons for this conclusion are (*a*) the metal is extremely pure; (*b*) the room temperature value of the susceptibility could be reproduced in the case of the cold-worked specimens after the specimen had been taken through a cycle at the higher temperature points; (*c*) complete absence of field-dependence of susceptibility; (*d*) had ferrous impurity in paramagnetic form been affecting the results, then the susceptibility would have been likely to diminish (numerically) at the low temperature, 90° K. Thus it is concluded that the decrease in diamagnetic susceptibility on cold-working indicates that copper is magnetically strain-sensitive.

Stoner[6] has suggested that increase in paramagnetic susceptibility with rise in temperature found by Sucksmith[7] in the alkali metals is due to thermal expansion. He deduces the approximate expression for the gram-atomic susceptibility for the quasi-free electrons:

$$(\psi_A)_e \times 10^6 = 32{\cdot}1\,(q/V_0)\{1 - 6{\cdot}11 \times 10^{-9}\,(T/V_0)^2\},$$

where q is the number of quasi-free electrons per atom and V_0 is the value of the maximum electron energy at absolute zero expressed in equivalent volts. Thermal expansion decreases V_0 and hence increases $(\psi_A)_e$. Cold-work, on the other hand, should also decrease V_0, since it may be considered as giving rise to a trapping of electrons in regions of lower potential energy. To account for the smaller decrease of susceptibility with temperature in the case of the cold-worked specimens, it is then necessary to suppose that further decrease in V_0 is less than for the annealed metal.

Further work will be published elsewhere.

'Incipient Shrinkage' of Collagen and Gelatin

IT is well known that if collagen is heated in water to about 62° C. it undergoes shrinkage, and that if it is then allowed to dry, its ability to re-hydrate on immersion in water is considerably reduced. Although opinions differ as to the precise mechanism of hydrothermal shrinkage, the phenomenon is generally agreed to be a cumulative effect in which the polypeptide chains, by the rupture of certain cross-links of various strengths, assume a more compact space arrangement than their hitherto extended forms. On drying in this compact state, their ability to take up water is considerably reduced, due probably to the formation of fresh inter-chain links.

A similar reduction in the re-hydrating power of collagen, but not accompanied by shrinkage, can be obtained by heating it in an atmosphere of high relative humidity at temperatures so low as 45° C. Deaminated collagen and gelatin also show this effect, and in the case of gelatin, it is accompanied by an elevation in 'melting point', which may amount to as much as 50° C. or more, where thin gelatin layers are concerned. Under conditions of very high relative humidity (*c.* 100 per cent) gelatin undergoes marked hydrothermal shrinkage at 45° C., and exhibits rubber-like properties similar to shrunken collagen, a phenomenon not usually observed with gelatin on account of its ready solubility in water at about 35° C.

The accompanying table shows the magnitude of the changes in absorption of water of the three proteins referred to, brought about by heating in atmospheres of various relative humidities at 45° C. In each case, after heating at 45° C., the protein was allowed to come to equilibrium with an atmosphere of 70 per cent relative humidity at 20° C., and in no case did the final weight differ from the original, before heating, by more than 1 per cent. The water absorption figures indicate the grams of water absorbed by 100 gm. of protein when immersed in distilled water at 20° C. for three days in the case of the collagens, and 36 hours in the case of gelatin.

Protein	Period of heating at 45° C. (days)	Relative humidity (%) 54	69	82	*c.* 100
Collagen	5	126	124	113	111
	20	104	103	93	88
	80	97	94	90	75
Untreated collagen, 126 ; shrunken* collagen, 95					
Deaminated Collagen	5	100	102	100	92
	20	86	89	89	76
	80	85	84	74	58
Gelatin	5	645	643	567	435†

* Collagen shrunken by immersion in distilled water at 90° C. for 3 min., allowed to dry out at 20° C. Some gelatinization had occurred, and therefore the water uptake figure given is probably higher than the real value for shrunken collagen.

† Hydrothermal shrinkage observed.

Air-dried collagen, containing about 13 per cent of water, can be heated in air to at least 100° C. without showing signs of shrinkage. Only when heated at this temperature in an atmosphere of practically 100 per cent relative humidity, or in the presence of excess water, does shrinkage occur. Since heating a protein in an atmosphere of high relative humidity is merely equivalent to heating it under conditions of comparatively high water content, it is apparent that a certain minimum water content is necessary before shrinkage can take place, even at temperatures so high as 100° C.

It seems likely that the effect which has been described is due to the rupture of some of the weaker cross-bonds of the protein molecule, which permits local increases in compactness, followed, on drying, by the formation of new cross-bonds. Physical shrinkage is not observed since insufficient links are so affected.

On this hypothesis, the term 'incipient shrinkage' seems appropriate to describe the phenomenon.

Exchange between Chromium Ions and the Szilard Effect

CHROMIUM hydroxide ($Cr(OH)_3$) was subjected to the action of slow neutrons produced by the cyclotron of the Collège de France and was then transformed into the sulphate by dilute sulphuric acid. Potassium dichromate was added to this solution of the sulphate so as to obtain an equimolecular system of Cr^{+++} and $\frac{1}{2}$ $Cr_2O_7^{--}$. After a time which varied from 15 to 120 minutes, the chromic salt was precipitated by boiling with ammonium hydroxide and the dichromate as the barium salt.

The activities of these precipitates, as measured by a Geiger–Müller counter, showed that in the neutral or acid medium there was no appreciable exchange. The following, for example, are the results obtained for a solution of *p*H about 3.

Time of contact	$Cr(OH)_3$	$BaCrO_4$
15 min.	116 ± 10	10 ± 7
60 ,,	83 ± 10	0 ± 6
120 ,,	71 ± 10	7 ± 6

Potassium iodide, which catalyses the exchange between arsenite and arsenate, has no action in our case.

The impossibility of observing an exchange between the Cr^{+++}, $Cr_2O_7^{--}$ ions leads one to think that it would be easy to find a Szilard and Chalmers effect with the dichromate. 500 gm. of dichromate were, therefore, irradiated with neutrons and dissolved in several litres of water which contained 200 mgm. of chromium sulphate. The latter was precipitated by ammonia and the hydroxide separated by centrifuging. The activity of the precipitate was found to be of the order of 100–300 counts/min., whereas the total activity of the dichromate was 30,000 or more counts/min.

Thus, if a Szilard and Chalmers effect does exist in this case, it is extremely weak.

Evidence for the Formation of a Copper Carbonyl

IN order to explain the 'metallization of insects' observed by Zelinski[1], and his own observation of a copper mirror produced by passing carbon dioxide through a heated tube containing a mixture of copper oxide and charcoal, Bertrand[2] postulated the intermediate formation of a copper carbonyl. Mond and Heberlein[3], being unable to reproduce Bertrand's results, were of the opinion that the deposition of the copper mirror was caused by the adhesion and sintering of copper oxide helped by its heat of reduction by carbon monoxide. The existence of a copper carbonyl has also been postulated by Boomer, Morris and Argue[4] to explain the removal of copper from the metallic catalyst during the synthesis of methanol.

In order to remove traces of oxygen from carbon monoxide, I heated a roll of copper gauze (initially slightly oxidized at the end of the roll nearest to the point of entry of the gas) in a glass combustion tube, by means of an electric furnace, the temperature in the centre of which was maintained at about 550° C. while the carbon monoxide (containing a little air, but no chloride) was being passed through the tube. During the course of several weeks of continuous heating in the stream of carbon monoxide, a substantial copper mirror was formed in the section of the tube which had attained a temperature of about 250–400° C., and a purple mirror in the centre section (550° C.). As the copper gauze was only in contact with the glass tube at a few points, and copper is non-volatile at the temperatures of the experiment, this phenomenon can best be explained by the formation of a very minute quantity of copper carbonyl at about 250° C., and its subsequent decomposition at higher temperatures. The purple coloration is due to interaction between the deposited metallic copper and the glass at the highest temperature (cf. Mond and Heberlein). A similar experiment using nitrogen instead of carbon monoxide did not produce a copper mirror, the glass tube remaining quite clear.

The fact that a copper mirror was deposited in a part of the tube where no copper oxide was present at any time means that Mond's criticism of Bertrand's experiments is inapplicable in this case. A minute deposit of a brown substance (free from chloride) in the cooler part of the glass tube may be the actual carbonyl. Tests were made for the presence of a chloride impurity, which could produce a white sublimate of cuprous chloride (cf. Robinson and Stainthorpe[5]), but this was found to be absent.

It is planned to carry out further investigations on this subject.

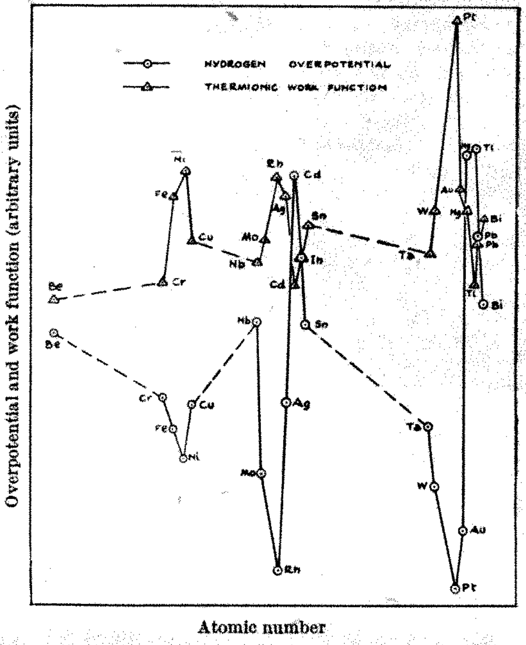
Hydrogen Overpotential and the Thermionic Work Function

EXTENSIVE recent work[1,2] on the hydrogen overpotentials at a large number of metal electrodes in aqueous solution allows a re-evaluation (see ref. 3) to be made of the relation between the hydrogen overpotential at various cathodes and the position of the cathode material in the periodic table. In the accompanying graph, the available values[1,2] for the hydrogen overpotential at the intermediate current density of 10^{-3} amp./sq. cm. at various cathode materials, the surfaces of which have been prepared in approximately the same way, are shown in relation to the atomic number of the metals concerned, from which a periodic variation may clearly be discerned.

It is of interest to compare this variation with the corresponding one for the thermionic work functions of the metals[4]. From the graph it seems tnat if, on transition from one metal to another, the second has a smaller overpotential than the first, then the second has a larger work function than the first, and *vice versa*. This relation appears to hold in every case for which data are available. There is also a general tendency for metals at which there is a comparatively low overpotential to have a comparatively high work function. The tendency for the converse is less marked.



According to Gurney's theory of hydrogen overpotential[5], the potential of a working electrode is directly related to its work function, and it appears from the theory that a high work function should tend to be associated with a large overpotential. According, however, to Adam[6], no relation between work function and overpotential is indicated by Gurney's theory, because "although electrons have to be extracted from the metal, they do also in a reversible electrode, and in either case the [work functions] cancel out . . . through a second contact potential elsewhere in the circuit". Both these interpretations seem in disagreement with the observed relations; the latter appear at variance in general with theories of hydrogen overpotential which postulate that the transfer of an electron from electrode to ion is the slow stage in the reactions occurring at the cathode[7,8].

As the work function of a metal is a measure of its electron affinity, it must be a measure of the tendency of the metal to take an electron away from the hydrogen atom and bind it to itself. Thus, it might be expected that the work function of metals would run roughly parallel to the ability of the latter to adsorb atomic hydrogen. Metals of comparatively high work functions, for example, nickel and platinum, would thus be expected to tend to act as comparatively good catalysts for the formation of molecular from atomic hydrogen. If, therefore, it be assumed that a catalytic reaction of adsorbed hydrogen forms the limiting stage in hydrogen overpotential, it follows that a large work function should correspond to a low overpotential, and the general features of the graph become more intelligible.

It may finally be noted that the order of increasing activation overpotentials of the metals is roughly the converse of their order with respect to hydrogen overpotential[9,10]. Thus for metal overpotentials, where the probability of a catalytic mechanism is remote, there appears to be a rough parallelism between work function and overpotential, as would be expected from the neutralization theory[11].

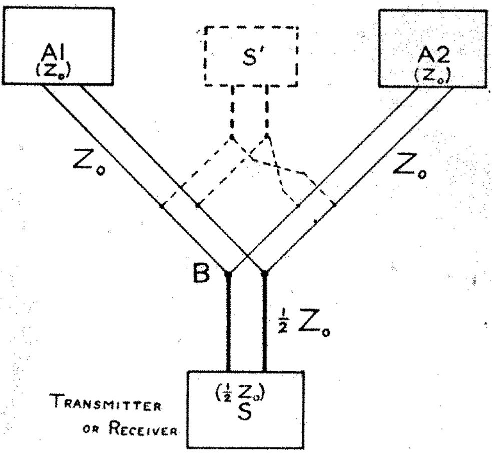
Apparent Breakdown of the Reciprocity Law for Transmission Lines

RADIO-FREQUENCY transmission lines are normally 'matched' for maximum power-transfer by making the load impedance as transformed by the line equal to the complex conjugate of the generator impedance. One consequence of the reciprocity theorem is that the same matching condition applies when the transmission takes place in the opposite direction, that is, the functions but not the impedances of the load and generator are interchanged. In an application to multi-element directive arrays, an apparent failure of this principle has been found. Further examination has elucidated the reason for the paradox, but as it is felt that the behaviour of such arrays for incoming radiation is not generally understood, the facts seem worth recording. Similar considerations may arise in other radio-frequency problems (for example, nuclear physics accelerators) where branching feeders are used.



Consider the system shown in the figure, where the parallel lines represent transmission line of the characteristic impedance indicated, omitting for the present the dotted lines. If $A1$ and $A2$ are aerials of impedance Z_0 each, the generator S feeds into $\frac{1}{2}Z_0$ due to the two loads being joined in parallel at B, so that the matching condition is that the impedance of S should be $\frac{1}{2}Z_0$, and pure travelling waves are generated in the feeders. For the case of reception of incoming radio waves, the matching condition appears not to be satisfied; for example, $A1$, having impedance Z_0, feeds into $\frac{1}{2}Z_0$ at B due to $A2$ and S in parallel, and one would expect reflexion of incident energy to occur at B. However, when transmitting, the aerial elements $A1$ and $A2$ were energized in phase, giving directional propagation—usually along the array-normal. For a received wave arriving along the array-normal, $A1$ and $A2$ will be energized in phase, and then it is easily shown that no energy is reflected at B, the system being equivalent to two generators of impedance Z_0 in parallel feeding a load of $\frac{1}{2}Z_0$.

Thus we see that although reciprocity does not hold for a part of a directive array considered separately, it holds for the complete system; and if the direction of radiation is reversed the matching condition is unchanged. Absence of reflexion at B only occurs for waves arriving along the array-normal (energizing $A1$ and $A2$ in phase). Waves arriving along another direction may energize $A1$ and $A2$ equally in antiphase; complete reflexion then occurs at B, all the energy being re-radiated, and none reaches the receiver, whatever its impedance. Incidentally, the resulting polar-diagram zero has an exact counterpart in the converse process of radiation from the array. For the general incoming wave both modes are excited, so that partial reflexion of energy occurs at B, just as it did in the case already considered in which only $A1$ was energized. The only matching condition which we can apply is that for the part of the energy in the in-phase mode, which is just the reciprocal of the matching condition for the transmitting case. However, application of this condition does not preclude the reflexion of energy, as it would in a simple feeder system.

In a radar application described in detail elsewhere[1] this principle is extended by the addition of the feeders, shown dotted in the figure, giving a feeder bridge having four arms each λ/4 long. By this means the energy in both modes (phase and antiphase at *A*1 and *A*2) can be absorbed, one mode into each of two receivers, the array then giving two polar diagrams simultaneously and quite independently into the two receivers. In such an arrangement neither receiver absorbs any power which could have reached the other receiver, even if that had been the only receiver present, but receives only energy which would otherwise have been re-radiated by the array.

Spiral Cracks in Glass Tubing

DR. J. J. HOPFIELD's description of spiral cracks in glass capillary tubing[1] reminds us that similar cracks were observed some ten years ago with thin-walled tubing, during the development of 'flashed' sodium-resistant glasses. The tubing in question was a conventional soda-glass, about 5 mm. in external diameter and rather less than 1 mm. in wall thickness, flashed internally with a thin layer of rather weak sodium-resistant glass. Specimens of such tubing in which the expansions of the two glasses were not sufficiently closely matched developed, soon after drawing, spiral cracks. The pitch of the crack increased towards the end of the stick of tubing, as in the specimen described by Dr. Hopfield, and tended to become infinite. In addition, the slope of the spiral varied throughout each turn in a regular manner. Cracks of the type described were only found in tubing having very high strain between the flashing and the base glass, the circumferential tension in the flashing glass corresponding to a stress of about 200 kgm. per sq. cm., a figure of the same order as the average breaking stress of the glass.

Friction and Wear

IN the literature of friction it has been generally assumed, often implicitly, that there is no causal relationship between wear and friction. Schnurmann[1] has shown that the results of measurements of static friction on naked cadmium surfaces at temperatures down to − 100° C. indicate that abrasion cannot be the only factor responsible for the elementary mechanism of friction, and that an essential part is played by deformation. The following treatment, however, provides direct evidence for this lack of a causal relationship. It is shown that the work involved in that portion of the abrasion which actually results in wear is a negligible proportion of the frictional work.

The amount of work required to abrade material from the bearing surface will be a maximum if this material is all removed as single atoms, and this maximum amount of work may, therefore, be calculated from thermochemical data leading to the heat of atomization of the materials involved. If the frictional force operating during a wear determination is measured, we can then calculate both the total frictional work and the maximum work necessary to produce the observed amount of wear.

For a composite material containing 69 per cent by weight of calcite and 31 per cent by weight of an *o*-cresol formaldehyde resin of approximate empirical formula (C_8H_8O) tested against mild steel with a normal pressure of 50 lb./sq. in. at a speed of 50 ft./sec., the highest wear recorded corresponded to abrasion of 1 gm. for the expenditure of 726 kcal. of frictional work. The approximate heat of atomization of the material may be derived from the published values of the heat of formation of calcite, the heat of combustion of *o*-cresol with allowances for the additional atoms and bonds involved in the resin, and the heats of combustion and of atomization of the elements involved.

The heat of atomization of 1 gm. of the material is thus found to be 10·6 kcal., or 1·4 per cent of the total frictional work done. It follows, therefore, that the proportion of the frictional work to be ascribed to this abrasion process is probably several orders of magnitude less than 1 per cent, when allowance is made for the abrasion of particles considerably larger than single atoms.

The wear of the steel bearing-member was not measured in the above work and was not allowed for in the calculation. It was measured in another experiment in which it was known to be very much larger, and even in this case a similar calculation showed that it could not account for more than 1 per cent of the total work done. The above conclusion is therefore not affected.

In order not to prejudice the argument, high values have been used in the thermochemical calculation for those quantities the true values of which may still be open to question, for example, the latent heats of vaporization of calcium and carbon.

Control of Low-Temperature Injury in the Victoria Plum

IT is well known that many kinds of fruit and vegetable after picking may be damaged during storage at low temperature above the freezing point. The phenomenon has been widely studied, and there is a considerable literature on the low-temperature injury relations of the apple, plum, peach and grapefruit. That the conditions known as low-temperature internal breakdown of the apple and plum, as well as woolliness of peaches and pitting of the rind of grapefruit are the final and visible result of a series of reactions deriving from an initial and sustained shift of metabolic balance, has seemed fairly evident. But observations of the influence of 'external' factors of primary importance, namely, level of temperature and duration of exposure as well as of 'internal' factors such as varietal type, degree of ripeness at picking, etc., have revealed a considerable complexity which cannot be elucidated by any simple hypothesis. It has, for example, been observed that after a limited period of exposure, the maximum percentage of injured fruits (plums and grapefruit) will often be found in samples subjected to storage at temperatures of an intermediate range. But after more prolonged exposure the highest proportion of injured fruits is found at the lowest temperature of storage.

Van der Plank and Rees Davies[1] have provided for these observations an ingenious explanation ; they have suggested that the lower the temperature the greater is the amount of *actual* injury. But the lesser injury sustained at higher temperature becomes manifest more rapidly. Thus when the percentage of injured fruits after exposure of moderate duration is plotted against temperature of storage, a typical humped curve is obtained, which, however, with longer exposure becomes transformed to a sigmoid curve with a maximum at the lowest temperature and tailing to zero at some higher temperature. In its final form this curve represents the limit of manifest injury.

More recently, Plank[2] has criticized the theory of Van der Plank and Rees Davies and has suggested that there are two main types of reactions involved, one leading to an accumulation of a cell-poison (*Zellgift Bildung*) and the other to its removal (*Zellgift Veratmung*). The reaction velocities for the processes that lead to the accumulation of the cell-poison and for those which lead to its removal are both related to temperature by equations of the form

$$\log y = \log y_0 + at,$$

where y_0 is the reaction velocity for $t = 0°$ C. and a is its temperature coefficient. The values of a may vary within limits dependent upon the values of Q_{10} which are to be expected in the metabolism of plant tissue. By selecting values of a, he produces pairs of curves within the co-ordinates y and t which intersect at a critical value of t, that is, at which the rates of production and removal of poison are equated. For a given fruit of critical temperature t_K, exposure for any length of time to higher temperatures will not result in injury, but exposure to lower temperature will produce injury in longer or shorter time. From statistical considerations it is supposed that a given sample of fruits will have a frequency distribution of critical temperature, which will fit a curve of binomial form, and Plank builds curves based on the variations of the constants of his equations, resembling the experimental curves for low-temperature injury published elsewhere.

I have[3] previously raised the objection to an all-embracing theory of this sort for plums on account of the observed fact that at least two types of injury can be symptomatically distinguished, and that the form of the temperature-injury curve is more complex than that suggested by other investigators. Plank[4] assumes in explanation of my curves that there are two superimposed sets of processes, each tending to a distinctive end-point and with quite different reaction velocity constants.

Recent observations I have made are of interest both practically and in connexion with the above considerations, since they are not inconsistent with a theory of production and removal of a toxic substance. It has been found that when Victoria plums are exposed to a temperature of 31° F. for a period of five weeks, they are damaged to the extent of 100 per cent, the type of injury being that known as 'internal browning'. If, however, between the 15th and 20th day of exposure they are warmed to 65° F. and only returned to 31° F. after two days, they can then be exposed to the lower temperature for a further period of 15–20 days without injury. An extension of this further period beyond 20 days results in the appearance of internal browning. Warming on the 5th or 25th day only partially reduces the proportion of injured plums. Warming at day 0 (delayed storage) has scarcely any effect.

It is relevant to recall that Kidd and West[5] reported in 1935 a somewhat similar phenomenon when they subjected apples susceptible to a functional disorder known as 'superficial scald' to brief intermittent warming treatments when stored at 3° C. There resulted an almost complete control of scald.

These experiments, therefore, show that the life of the Victoria plum may be extended by as much as 50–75 per cent of that previously possible if the fruit is stored at 31° F. and warmed for two days between the 15th and 20th day.

The way, therefore, seems open to investigations which may possibly have some far-reaching effects upon practice in handling those types of fruits which are susceptible to low-temperature injury.

Details of these experiments are shortly to be published elsewhere, and further investigations along these lines are being projected.

A Morphological Change Induced in Leaves of *Theobroma* cacao by Mineral Deficiency

PREPARATIONS for breeding a strain of *Theobroma cacao* L. resistant to the swollen-shoot virus which threatens the cacao industry of the Gold Coast[1] have included the collection of commercial types of *T. cacao* and of related species of *Theobroma*, some of which have been shown to give compatible crosses with *T. cacao*[2]. With the assistance of the Imperial College of Tropical Agriculture, seed from selected trees has been introduced to the Gold Coast from Trinidad. As a precaution against the introduction of witches' broom disease (*Marasmius perniciosus* Stahel) pods were surface-sterilized before dispatch by air ; seedlings were quarantined for a minimum period of six months in Accra, which is twenty miles distant from the cacao-growing area.

Distressing signs of lime-induced chlorosis appeared in a number of early importations which had been potted in a mixture of soil, compost and marine sand containing a high percentage of shell, and had been watered with limed water. In addition to symptoms of acute iron deficiency, a few plants showed a leaf deformation which consisted of a number of sharp entations at the leaf tip: a normal cacao leaf is ntire (Fig. 1).

This deformity has been reproduced in exaggerated rm in cacao seedlings grown in water cultures lacking both iron and manganese. The basic solution f Reeve and Shive[3] was used at a potassium con-entration of 50 p.p.m. with the addition of 0·5 p.p.m. ach of boron and zinc. Plants were grown in black-ned glass jars of 800 ml. capacity; the solutions ere aerated daily and adjusted weekly to a reaction f *p*H 6·0. There were four replicates of the treatment, each of which produced deeply indentate eaves (Fig. 2) in a flush of growth developed in leven to thirteen weeks after transference to culture. leven out of a total of fifteen leaves were affected; hey were chlorotic and afterwards developed tip corch (Fig. 3). The plants ceased elongation after wenty weeks in culture and produced no more leaves efore dying.

The four plants had been taken at random from wenty seedlings which had been grown for eleven eeks in quartz sand and distilled water; the re-naining sixteen seedlings produced entire leaves hen grown under parallel conditions in solutions ontaining 1·0 p.p.m. iron and 0·25 p.p.m. manganese. nly entire leaves have been formed by a second eries of forty plants, including eight lacking only ron and eight lacking only manganese, which have een grown for periods of up to thirty weeks in the ame basic solution.

Since leaf shape, particularly the degree of dentation, may be used to separate species in certain enera, any induced modifications are of general nterest. Harder and his colleagues have produced a hange from entire to dentate leaf form in certain ucculent plants by increasing the length of day[4]. They have shown that a leaf exposed to long days can transmit a stimulus which gives rise to long-day character in other leaves; the stimulus apparently travels in the plant along the same path as solutions injected through the petiole of the exposed leaf[5].

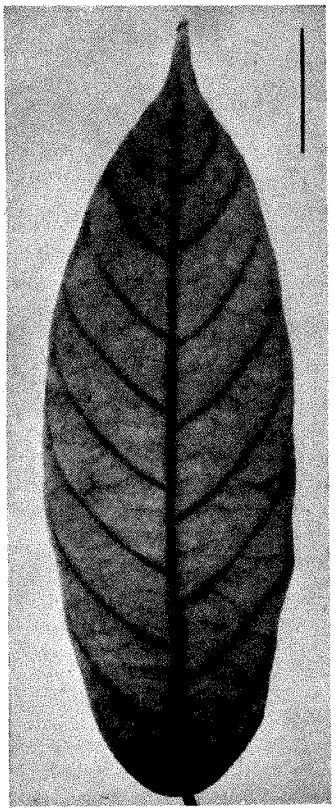

Fig. 1. NORMAL CACAO LEAF

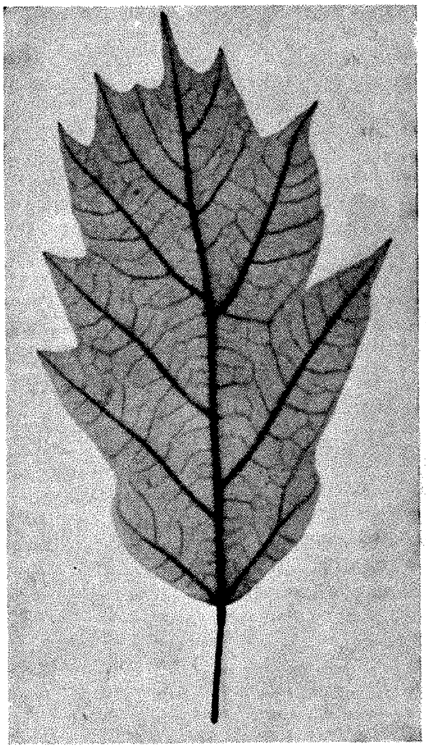

Fig. 2. INDENTATE LEAF FROM CULTURE LACKING IRON AND MANGANESE

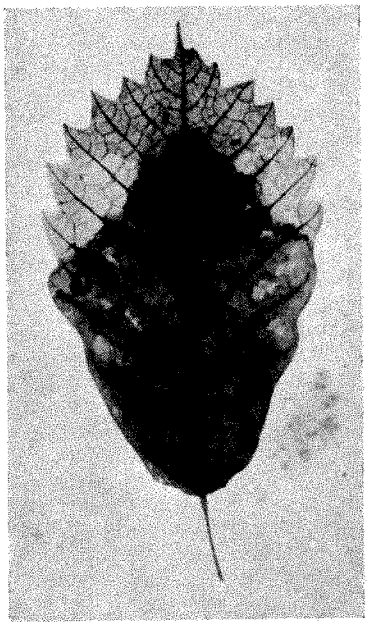

Fig. 3. TIP SCORCH DEVELOPED BY INDENTATE LEAF ON AGEING

There would, however, appear to be no record of the production, by manipulation of the mineral nutrient supply, of a change of leaf shape comparable to that here described. While modifications of leaf size and thickness are associated with deficiencies of a number of major and minor elements, changes in leaf outline are usually slight, the more notable being those accompanying zinc deficiency.

Mechanism of Hydrogen Peroxide Formation by Spermatozoa and the Role of Amino-Acids in Sperm Motility

IT has been demonstrated[1], using freshly ejaculated bovine semen diluted with egg-yolk medium, that spermatozoa produce under aerobic conditions an inhibitor of sperm respiration. The inhibitor was afterwards identified chemically[2] as hydrogen peroxide, and was shown to be formed as the result of metabolic activity of spermatozoa upon a substance present in the egg-yolk and its dialysable portion. Since then, further purification and characterization of the egg-yolk substance have been carried out; and it has now been demonstrated that hydrogen peroxide is formed as the result of an oxidative deamination by spermatozoa of the substance isolated, which is replaceable, with the same effect, only by *l*-tryptophane, *l*-phenylalanine and *l*-tyrosine, but not by any of many other amino-acids tested. The inhibition which develops as the result of the above reaction can be detected not only by its effect upon oxygen consumption but also by its effect upon the reduction of motility of spermatozoa.

The isolation of the substance, in presence of which spermatozoa produce hydrogen peroxide, was effected by dialysis of egg-yolk, followed by successive precipitations and/or extractions with organic solvents of the dialysable portion or the fractions separated therefrom. The isolated substance is easily dialysable, and soluble in water, 90 per cent ethanol and *iso*-propanol. It is not fermentable by baker's yeast. Quantitative analysis revealed that it contains 10·7 per cent nitrogen, 4·2 per cent ash and 0·13 per cent sulphur (Weiler and Strauss), no phosphorus nor fermentable reducing substances. In low concentration it gives strong reactions for tryptophane and tyrosine. Only traces of glucosamine were detected before or after acid hydrolysis.

Washed suspensions of living spermatozoa of the bull, in the presence of the isolated substance, produced aerobically ammonia and hydrogen peroxide; under anaerobic conditions, however, there was neither ammonia nor hydrogen peroxide formation, and subsequent respiration and motility were unaffected. The ash of the substance had no appreciable effect on either respiration or motility. Spermatozoa inactivated by heat in presence of the substance and molecular oxygen produced neither ammonia nor hydrogen peroxide.

In view of the properties of the substance isolated, natural amino-acids were next tested individually as substrates for the metabolism and motility of bovine spermatozoa. This examination revealed that formation of ammonia and hydrogen peroxide, and subsequent inhibition of sperm respiration and motility, took place aerobically in the presence of only *l*-tryptophane, *l*-phenylalanine and *l*-tyrosine. There was neither ammonia nor hydrogen peroxide formation in the absence of oxygen or with heat-inactivated spermatozoa. The inhibition of sperm respiration and motility in presence of these substances was completely eliminated with added catalase (more than 10 μgm./4 ml. sperm suspension). In the presence of *dl*-alanine, *dl*-serine, *l*-cysteine, *dl*-valine, *l*-leucine, *l*-arginine, *l*-lysine, *l*-hystidine, *l*-aspartic acid and *l*-glutamic acid, there was no inhibition of either sperm respiration or motility, and no formation of ammonia or hydrogen peroxide.

These results suggest that the reaction by which hydrogen peroxide is formed by living spermatozoa is an enzymic dehydrogenation and deamination proceeding in the presence of molecular oxygen as hydrogen acceptor as follows:

$$R.CH_2.CH(NH_2).COOH + O_2 + H_2O \longrightarrow R.CH_2.CO.COOH + H_2O_2 + NH_3$$

where *R* can be only phenyl, *p*-hydroxyphenyl or indolyl groups, but none of the other groups tested. The *l*-amino-acid oxidase (or oxidases) of living bovine spermatozoa, which affects only the three aromatic amino-acids, appears to be, therefore, more specific than the *l*-amino-acid oxidase present in some other animal tissues, which can utilize as substrates a much larger range of *l*-amino-acids[3,4].

These findings may have an important bearing on the fertilizing capacity of spermatozoa, and on their storage and survival in storage media, such as egg-yolk, and in natural secretions, especially in view of the fact that *l*-tryptophane, *l*-phenylalanine and *l*-tyrosine are widely distributed in animal tissues and body fluids. Moreover, the spermatozoa have an exceptionally low capacity for decomposing hydrogen peroxide; and hydrogen peroxide, even in very low concentrations which have not so far been chemically detectable, has a detrimental effect on the respiratory activity and motility of spermatozoa, as demonstrated by the elimination of these effects in presence of added catalase.

This work, carried out on behalf of the Agricultural Research Council, will be published in detail elsewhere.

The Water-balance Principle of Crustacean Eye-stalk Extracts

IT has long been known[1] that extracts of crustacean eye-stalks contain a principle which not only influences the colour changes of crustaceans but also induces expansion of the melanophores in amphibians, acting in this respect like the intermediate lobe pituitary hormone. It was therefore of considerable interest when Gray and Ford[2] reported that extracts of crustacean eye-stalks produce an increase of water uptake in frogs similar to that observed after the injection of neurohypophysial extracts. No structure homologous to the vertebrate neurohypophysis has so far been identified in invertebrates; but the results of the American authors suggest the possibility that crustaceans, although they have no pituitary gland, elaborate pituitary-like hormones.

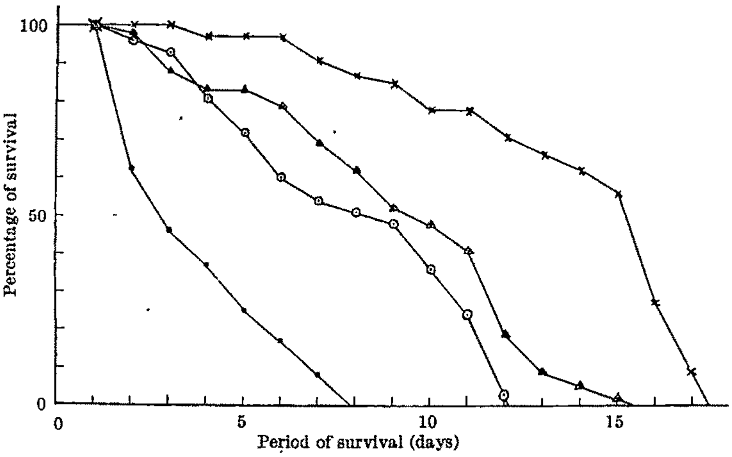

Fig. 1. VIABILITY OF *Echinorhynchus truttæ* IN DIFFERENT CONCENTRATIONS OF SODIUM CHLORIDE SOLUTION

●, 2 per cent sodium chloride. ×, 1 per cent sodium chloride.
▲, 1·5 ,, ,, ,, ,, ⊙, 0·75 ,, ,, ,, ,,

However, the similarity between the 'water-balance effect' of extracts of vertebrate pituitaries and that of extracts of crustacean eye-stalks is scarcely sufficient to characterize the eye-stalk factor as a pituitary-like principle. It was therefore decided to investigate whether crustacean eye-stalk extracts showed any of the other pharmacological actions of neurohypophysial preparations. Eye-stalks of the brackish water crab *Carcinus mænas* and of the fresh-water crayfish *Potamobius fluviatilis* were extracted according to the pharmacopœial method for the preparation of mammalian posterior pituitary extracts. Such extracts had a marked water-balance effect in frogs, but failed to give a significant pressor response in the spinal cat or an antidiuretic response on the unanæsthetized rabbit. Considering that most of the water-balance activity of mammalian neurohypophysial extracts is contained in the oxytocic fraction[3,4], the action of crustacean eye-stalk extracts on the isolated guinea-pig uterus was also examined. So was another action typical for the mammalian oxytocic fraction, namely, the action on the urinary chloride excretion in rats[5,6]. Negative results were obtained in both series of experiments.

No evidence could thus be obtained that the crustacean and the vertebrate water-balance factor are homologous principles; but although the water-balance activity of mammalian neurohypophysial extracts follows closely their oxytocic potency, it will have to be considered that this parallelism does not necessarily hold for non-mammalian pituitary extracts. For example, it has been shown[7] that frog pituitary extracts which per gland exerted a water-balance effect equivalent to that of 0·80 unit of the standard (mammalian) posterior pituitary extract, contained less than 0·04 unit of oxytocic activity. These results suggest that the vertebrate water-balance factor may have to be differentiated not only from the antidiuretic but also from the oxytocic pituitary hormone. It is therefore conceivable that a substance occurs in crustacean eye-stalk extracts which is related to the water-balance principle of vertebrate pituitaries but unaccompanied by any of the other neurohypophysial activities.

Acanthocephala of Trout and Anthelmintics: Behaviour *in vitro*

PRACTICALLY nothing is known of the *in vitro* behaviour of Acanthocephala to anthelmintics, and standard works[1-4] say little about treatment of these parasites *in vivo*. Although *in vitro* tests may possibly not reproduce exactly the response of helminth parasites *in vivo*, they give an opportunity of comparing directly the action of a large number of drugs in a shorter time; and results so obtained may suggest a method of combating Acanthocephala in the living host. With these objects in view the present investigation was carried out.

Echinorhynchus truttæ (Acanthocephala), a common parasite of the brown trout (*Salmo trutta*), was selected for experiment. The most active worms were used. Contact with metallic instruments and exposure to light were avoided, as these were found to have a deleterious effect on the parasites and hastened their death. In the survival experiments in various concentrations of saline, 288 individuals were used; and 330 in the experiments with various drugs.

The worms were kept alive in saline solution. According to Van Cleave and Ross[5], a 0·85 per cent sodium chloride solution is a suitable medium for maintaining the Acanthocephala of the turtle. For *Echinorhynchus truttæ*, however, a 1 per cent solution of sodium chloride appeared to be most suitable. In this solution the majority of the parasites retained their normal wrinkled appearance and survived for more than two weeks. In lower concentrations of saline the Acanthocephala became plump and showed bulging of the body cuticle, while in higher concentrations they assumed a more or less shrunken appearance; and in both cases the period of survival was considerably shortened (Fig. 1).

For testing the *in vitro* behaviour of the parasites to anthelmintics, a large number of experiments was carried out using different concentrations of various drugs which were suspended or dissolved in a 1 per cent sodium chloride solution. Control experiments were set up in each case. It was observed that certain anthelmintics, for example, carbon tetrachloride, thymol and copper sulphate proved fatal to the parasites at a concentration of 0·05 per cent and more (Fig. 2), while others, for example, santonin and sulphathiazole, did not produce any visible toxic effects even when used in a 1 per cent concentration. Oil of chenopodium usually killed the Acanthocephala if used at a concentration of at least 1 per cent; concentrations less than 1 per cent merely paralysed the parasites, which revived when afterwards transferred to a 1 per cent sodium chloride solution.

Without cytological examination it would be difficult to determine the exact nature of the damage caused by the anthelmintics to these Acanthocephala

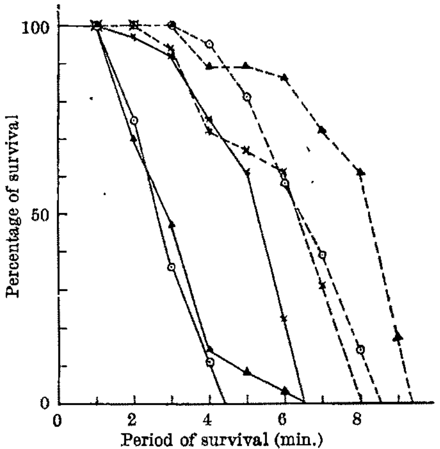

Fig. 2. VIABILITY OF *Echinorhynchus truttæ* IN 0·05 AND 0·1 PER CENT CONCENTRATIONS OF CARBON TETRACHLORIDE, THYMOL AND COPPER SULPHATE

.... 0·05 per cent. ⊙, carbon tetrachloride.
—— 0·1 „ „ ▲, thymol.
×, copper sulphate.

of the trout. The behaviour of the parasites, however, varied according to the drug used and its concentration. Both carbon tetrachloride and thymol brought about a rapid extroversion and introversion of the proboscis, accompanied by alternate expansion and contraction of the body. The movements were accelerated when higher concentrations of these drugs were employed. With these anthelmintics, the worms generally died in a fairly extended condition. Copper sulphate did not produce such marked effects, and with it there was scarcely any apparent difference in the activity of the Acanthocephala in different concentrations (0·05 per cent and 0·1 per cent solutions) except for a slight shortening of the period of survival in the higher concentration. With oil of chenopodium the worms showed a rhythmic expansion and contraction of the body, followed by a general wriggling movement. The body ultimately contracted and sometimes became S-shaped before the parasites finally became quiescent.

I take this opportunity of expressing my gratitude to Prof. James Ritchie for granting me facilities to work in his laboratory, and for the interest he has shown in my work.

"Criteria of Hybridity"

I REGRET that ambiguity in my article "Criteria of Hybridity"[1] has caused Prof. E. Anderson inconvenience. While discussing the 'index method' of investigating natural populations, I made the statement: "In the majority of cases known to the author where this method has been employed . . . its use has not been preceded by an artificial cross between the putative parent species, differences between those species being all that were known before the natural populations were investigated. The work of Goodwin . . . with *Solidago* is a exception."

By this statement it was intended to convey tha the references quoted were the cases known to m where the method had been employed, and that i the majority of them an artificial cross had not bee made. I feel that no one who is familiar with th excellent and extremely productive work of Anderso on the populations of *Tradescantia* in America will b unaware of the artificial crosses made and publishe by him[2] involving species concerned in two of th references (Anderson[3] (Section II), Anderson an Hubricht[4]). In any event such crosses are referred t in both publications.

Goodwin's work was picked out as exceptiona because it included a character-analysis of parent and artificial reciprocal crosses carried into the secon filial generation and including back-crosses to bot parents. In the remaining four papers quoted ther is no mention of artificial crosses having been mad prior to field investigations, and they are, therefor in the majority. In this amplification of my origina statement, it may be pointed out that Ownbey an Weber[5] do not, themselves, state that they hav used the 'index method' or publish keys, but I believ that reasoning of this sort was necessary to obtai the results which they report.

The quotation from Anderson[3] which appears i the same paragraph of my paper is taken from hi Section I ("A Method of Measuring Species Hybrids" which is not concerned directly with *Tradescanti* and the remarks made still stand, as the necessity fo prior experiment is not insisted upon in describin the method.

The Premaxilla and the Ancestry of Man

PROF. WOOD JONES' theory of human evolutio based on the premaxillary bone is, of course, wel known[1]. It depends on his assumption that it i legitimate to infer the phylogenetic antiquity of morphological character by noting the time of it ontogenetic appearance. However, attention is in vited to Ashley-Montagu's comprehensive study o the premaxilla of the primates[2], in which the autho reports that the apical portion of the premaxilla ma in some cases be observed on the facial aspect of th late fœtal and infant human skull, quite clearl separated from the maxilla by a distinct sutur I have recently had the opportunity of studying th original fossil Australopithecine material in Sout Africa, and gave particular consideration to th architecture of the upper jaw. There appeared to b no feature here which contradicts the conclusio put forward by Prof. R. A. Dart and Dr. R. Broo that the Australopithecinæ do indeed give ver important information regarding the primate for which were ancestral to *Homo*.

PROCEEDINGS OF THE PAN-AFRICAN CONGRESS ON PRE-HISTORY

A GENERAL account of the Pan-African Congress on Prehistory was published in *Nature* of February 15, p. 216. The following records the proceedings of the business meetings and supplements the former article.

Sixty-three papers were communicated to the Congress, and, in addition, four symposia were held, dealing respectively with "Pleistocene Marine Terraces", "Fossil Man in Africa", "The Hand Axe Culture in Africa" and "Fossil Apes in Africa".

Three sub-committees were set up to deal with problems relating to: (1) geology and general palæontology, under the chairmanship of Dr. S. H. Haughton; (2) human palæontology, under the chairmanship of Dr. A. Galloway; (3) prehistoric archæology, under the chairmanship of Mr. A. J. H. Goodwin.

A number of important resolutions, arising out of the deliberations of these committees, were placed before the Congress in its final session and duly passed. The most important of these dealt with the question of terminology in the African Continent, and, among other things, it was decided that in future:

(i) The Hand Axe Culture in Africa should be referred to as 'Chelles-Acheul' with suitable regional prefixes, instead of using such terms as 'Chellean', 'Acheulean', 'Stellenbosch', etc.

(ii) That the term 'Tumbian' should be abandoned, as well as 'Kalinian' and 'Djokocian', and that in substitution thereof the term 'Sangoan', with suitable definitive adjectives, be used for the earlier stages of the culture formerly described by the above terms, and the term 'Lupemban' for its later stages.

(iii) That the use of the term 'Aurignacian' for the blade and burin' culture in Africa be abandoned in favour of the term 'Capsian' with suitable regional prefixes.

(iv) That the use of the terms 'Clacton' or 'Clactonian' and 'Levallois' or 'Levalloisian' to describe *techniques* of working stone be abandoned, and that these terms be confined only to describing cultures and that the techniques should, in future, be described as 'block-on-block' technique and 'facetted platform technique' respectively, with suitable definitive terms where necessary.

(v) That the terms 'Kageran', 'Kamasian', 'Gamblian', 'Makalian' and 'Nakuran' should be used hroughout Africa to describe defined stratigraphical units, and based upon the established succession of faunas and deposits in East Africa.

Two permanent committees were set up to deal with the question of terminology in the fields of prehistory and quaternary geology respectively. It was decided that, in order to obviate the introduction of unsuitable terms into the literature of African prehistory, all workers should be invited to submit any suggested new names to the members of these committees for prior comment and advice. In this way it is hoped to avoid the creation of different erms for identical cultures in different parts of the Continent.

In its final plenary session, the Congress passed a number of resolutions addressed to Governments of countries in Africa, as well as to Governments of countries interested in research work of Africa, tressing the urgent need for further research work in the field of prehistory and quaternary geology, as well as human palæontology.

The Congress decided that, in view of the very important results achieved at this first Pan-African Congress on Prehistory, it was essential that the organisation should be set up on a permanent foundation. Rules and constitution were consequently drawn up and approved, and it was decided that a similar congress should be held at approximately four-yearly intervals.

While the Congress was in session, an official invitation was received from Field-Marshal Smuts for the Congress to hold its next meeting in the Union of South Africa in 1951, and this invitation was accepted.

The *Proceedings* of the Congress are now being prepared for publication, and many of the original papers that were communicated will appear in full. Advance orders for copies should be sent to the General Secretary, Pan-African Congress on Prehistory, P.O. Box 658, Nairobi, Kenya Colony.

RADIO-COMMUNICATION DURING THE WAR

AS already announced in *Nature*, the Radio Section of the Institution of Electrical Engineers held a Convention during March 25–April 2, at which about a hundred papers were presented describing the progress made in recent years in the subjects of radio-communication, broadcasting and certain types of navigational aids. The proceedings of this Convention, when published in the *Journal* of the Institution, will form a most useful record of war-time progress in radio research and development, complementary to that of the Radiolocation Convention held in 1946.

In his opening lecture on "Telecommunications in War", Sir Stanley Angwin gave some account of the remarkable achievements in this field in recent years, the success of which was undoubtedly due to very effective co-operation between the Government research establishments, the electrical and radio industry, and the Fighting Services.

The first three technical sessions were devoted to papers dealing with radio-communication over long distances and with the special problems encountered in the use of radio technique for military, naval and aeronautical communications. Owing to the limited range of radio frequencies which can be used for long-distance transmission, the band of frequencies allotted to each circuit must be used in the most efficient and economical manner possible. With this objective in view, considerable advances have been made in stabilizing the frequencies of radio-transmitters, in the use of single, in place of double, side-band modulation, and in the combined use of several adjacent narrow frequency channels keyed at a reasonably low speed for the purpose of sending messages between two points at very high speeds. In most forms of modern communication, whether for civil or military purposes, the radio-transmission path is merely a link connecting the land-line telegraph and telephone networks in the countries surrounding the terminal points. Recent developments have therefore taken account of the need for the systems of modulation adopted to be equally suitable for operating both the radio and land-line equipments.

In the application of communication to the modern very mobile army and to ships and aircraft, a number of severe limitations of space, size and weight are encountered; and the manner in which the corresponding electrical and mechanical problems have been solved were described in a series of papers dealing with this field. One of the outstanding achievements of the War was the development and use by the army of the No. 10 set, which, with a carrier wave-length of about 6 cm. and the use of pulse modulation technique, provides multiplex radio telephone facilities in an equipment of a highly mobile form. At the above wave-length the use of a large parabolic reflector gives a concentrated beam of radiation with a consequent high degree of privacy in communication. Although the effective range of each such set is in practice limited virtually to optical distances, the efficiency is such that many sets can be used in series; and it was in this way that Field-Marshal Montgomery was enabled to maintain direct telephonic communication with London during his advance through Germany.

While, as several papers described, the use of very high frequencies, corresponding to wave-lengths of a few metres and less, now plays an important part in communication, particularly for air-to-ground and other relatively short-distance operation, the bulk of long-distance communication is necessarily confined to those frequencies which are efficiently transmitted by reflexion from one or other regions of the ionosphere. In opening the session on "Propagation", Sir Edward Appleton described the British work on the exploration of the ionosphere during the past twenty years or more, and the manner in which such long-term measurements are applied to the prediction of average ionospheric conditions some months ahead. In a following paper, Messrs. K. W. Tremellen and J. W. Cox described the work of the Inter-Services Ionospheric Bureau, which was set up during the War to provide detailed forecasts of communication conditions as required from day to day for various parts of the world. The techniques thus evolved are being improved and applied to peace-time communication problems, the basic scientific work being carried out at the National Physical Laboratory under the auspices of the Radio Research Board of the Department of Scientific and Industrial Research.

At a later session, Mr. H. Bishop presented a paper in which he described the large and important part played by the Engineering Division of the British Broadcasting Corporation during the War. Very elaborate precautionary measures were initiated before the War, to ensure that the broadcasting stations in Great Britain did not provide navigational assistance to enemy aircraft, and these proved to be very successful in practice. In addition, the expansion and maintenance of adequate propaganda and information services to Europe and other parts of the world necessitated the provision of new transmitting stations of various types. As a result, Great Britain now has at Ottringham, near Hull, the highest-power medium-wave broadcasting station in the world, with an output power to the aerial of 800 kW. In addition, the world's largest short-wave broadcasting station has been erected at Skelton, in Cumberland, where twelve 100 kW. transmitters and a system of fifty-one aerials have been installed.

Other papers dealt with recent advances in radio direction-finding and certain types of navigational aids for ships and aircraft; and the Convention was brought to a close by a lecture by Sir Clifford Paterson in which he reviewed the work of all the sessions and indicated the direction in which future progress in this subject is likely to be made. Much of the war time experience will bear fruit in peace-time applications, particularly in connexion with civil aviation trunk telephony, broadcasting, television and the industrial uses of radio frequency and electronic techniques.

FLUORIMETRIC ANALYSIS

A DISCUSSION was held in the rooms of the Chemical Society, Burlington House, on February 11, by the Physical Methods Group of the Society of Public Analysts, on "Fluorimetric Analysis"

The first paper was presented by Mr. E. J. Bowen as a basis for discussion of apparatus design. It was argued that although on occasion visual methods might be valuable in revealing unsuspected or unwanted changes in the colour of the fluorescence photocell instruments have the advantage of simplicity of operation and high accuracy. The best design would seem to be a central lamp sending in opposite directions two horizontal light beams which are made parallel by lenses, monochromatic by filters, and controlled in area by diaphragms. The beams each traverse a rectangular transparent cell of solution, one a standard and the other the one to be measured. The fluorescent light emerging at right angles to the beams is received (through filters) by two photocells connected in opposition. The measurements may be made either by the direct differential output of the photocells, or by balancing this to zero electrically or by a calibrated variable diaphragm in one of the light beams. The advantages of vacuum type photocells with valve amplification over barrier layer cells for this purpose were stressed, and it was pointed out that the still greater sensitivities obtainable with photo-electron multiplier tubes make them very suitable for fluorimeters to measure feeble fluorescence, and open up some interesting new possibilities.

A second contribution by Mr. Bowen dealt with the theoretical aspects of the 'quenching' of fluorescence in solution. It was suggested that this term should be confined to the phenomenon of the non time-dependent weakening of the fluorescence of a substance below a 'fluorescence efficiency' of unity This would rule out effects caused by instrumental errors or by residual unwanted fluorescence in the solvent, cells, or filters. The use of the term 'fluorescence fatigue' to describe examples of reversible photochemical action was criticized. A systematic classification of quenching processes into three main types was presented: intramolecular energy rearrangements, intermolecular effects, and inner filter action. Experimental methods of distinguishing these types, and of the two kinds of intermolecular effects 'collisional' and 'compound' quenching, were described. The paper concluded with a brief account of the types of photochemical change often associated with fluorescent solutions.

Dr. E. Kodicek described precise methods he ha worked out for the fluorimetric analysis of such substances as riboflavine, vitamin A, etc., as a means o investigating nutritional problems.

Dr. D. M. Simpson (Cambridge) gave a shor account of the applications of fluorimetric analysis t the study of pterins. She emphasized the need fo the determination of standard spectra of synthetic pterins under controlled conditions of illumination and *p*H. At present such spectra are available only for xanthopterin and leucopterin.

Fluorescence spectra alone are insufficient to identify pterins in complex mixtures. Ultra-violet absorption spectra and chemical tests should also be employed. Using these complementary methods, it has been possible to demonstrate the presence of pterins in such diverse materials as the argentaffine cells of the stomach and intestine, the fluorescent substance obtained from the eye of the dog-fish (*Squalus acanthias*) and the 'uric acid pigment' prepared by heating uric acid and water in sealed tubes at 200° C.

Few quantitative determinations of the concentrations of pterins have yet been made using fluorescence spectra. Provided that suitable precautions are employed to avoid quenching and inner filter effects, the method should be feasible if synthetic material is available for comparison. Examination of a large number of liver extracts has suggested that the intensity of fluorescence might be used as a measure of the clinical activity of these preparations.

In discussion, Drs. Winch and Cooper described tests made with a G.E.C. photocell and valve with a grid-leak of 10^6 megohms, capable of detecting 10^{-11} lumens. The instrument can detect a concentration of 1 milli μ gm./c.c. of a fluorescent substance, below which the residual fluorescence or Raman radiation of the water interferes. Dr. Cooper criticized the use of double-beam instruments with a mercury lamp on account of the movements of the narrow arc thread with time. Dr. F. Wokes raised the question of temperature effects on fluorescence, and stressed the need for publication of adequate data on fluorimeter calibration in analytical papers. Dr. Ridyard welcomed clearer definitions of the term 'quenching' because of its relation to instrument design. He suggested that the device of a transparent glass plate at 45° to the beam to reflect some of the light might be a useful modification of the double beam arrangement. Dr. White suggested that a closer study of the types of quenching observed in different instances might prove a method of distinguishing substances with similar fluorescent emission. Dr. H. W. Thompson stated that the limiting factor of sensitivity in many fluorimeters is the fluorescence of the glass or gelatine filters used before the photocell. Drs. Griffiths, Gullerson and Ellinger also made interesting contributions to the discussion, which had been keen throughout and was brought to a close only by considerations of time and temperature.

RECENT SOLAR ACTIVITY

A PAIR of sunspots making a group of exceptional size crossed the sun's disk between March 31 and April 13 in lat. 24° south. The group was the return of that reported in *Nature* of March 22, p. 396, but meanwhile it had either grown or a new formation had developed, as seems more likely, giving an even greater area than during the first disk passage during March 3–17. This latest spot, with a peak area of about 5,400 millionths of the sun's hemisphere, now heads the list of the largest spots in the Greenwich photographic records begun in 1874–75. Even in the extended period covered by reliable drawings associated with Schwabe, Carrington and others, this spot probably holds its premier position for size. As will be seen from the list below, within fourteen months the largest four spots in the Greenwich record have occurred. For this alone, the present 11-year solar cycle will be remarkable, whatever further activity is in store during the next two or three years that should include the peak of spot-frequency of the cycle.

In one important respect, the latest spot has been surprising; no great magnetic storm, nor even a small one, occurred during the interval, two days before and four days after central meridian passage (April 6–8 U.T.), when great magnetic activity associated with big sunspots is most likely to begin. It is significant that available solar observations indicate an absence of marked chromospheric activity, especially intense solar flares, associated with the spot; but until central meridian passage few observations could be made in Great Britain owing to cloudy skies. However, radio data of fade-outs on short-wave long-distance transmission, as reported to the Royal Observatory, Greenwich, by Cable and Wireless, Ltd., entirely support the sampling from direct solar observation that no intense solar flare occurred over the spot when it was more nearly in line with the earth. Previous experience has shown that intense flares, such as those recorded with the two great sunspots of 1946, are synchronized by complete and prolonged fade-outs of an hour's duration or more on daylight circuits. The evidence for no intense flare will be virtually complete when similar data are obtained for daylight circuits during Greenwich night hours, in addition to solar observations made in America, Australia and India.

The list of giant spots that have exceeded 3,000 millionths of the sun's hemisphere on one or more days may now be given as follows. The areas given for the 1946 and 1947 spots are provisional only, pending the measurement at Greenwich of a completed series of photographs.

Year	Central meridian passage	Maximum area	Magnetic storm	
			Great or small	Begins
1947	April 6·8	5400	None	—
46	Feb. 5·5	4900	G	Feb. 7·4*
47	March 10·2	4300	s	March 8·3
46	July 26·8	3950	G	July 26·8*
26	Jan. 24·5	3716	G	Jan. 26·7*
38	Jan. 18·4	3627	G	Jan. 22·2*
37	Oct. 4·5	3340	s	Oct. 3·5
38	Oct. 11·9	3003	(s	Oct. 7·4)

An asterisk denotes that an exceptionally intense solar flare was observed in *Hα* (6563 A.) at one or more observatories at the following respective time-intervals preceding the beginning of the storm: 18, 26½, 24 and 29 hours.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, April 21

Institution of Electrical Engineers (at the Central Hall, Westminster, London, S.W.1), at 6 p.m.—Mr. J. Hacking: "The Generation and Wholesale Distribution of Electricity" (Faraday Lecture).*

Society of Public Analysts and other Analytical Chemists, Biological Methods Group (in the West Hall, Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 6 p.m.—Symposium on "The Production and Care of Laboratory Animals", Part 2. Dr. H. J. Parish: "Common Diseases"; Mr. N. T. Gridgeman: "Records".

Royal Statistical Society, Sheffield Group of the Industrial Applications Section (at the Royal Victoria Station Hotel, Sheffield), at 6.30 p.m.—"The Application of Statistical Control to Research and Testing".

Tuesday, April 22

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. W. A. J. Paul: "Photography in the Post Office".

Institute of Physics, Electronics Group (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. S. Rodda: "Electron Multipliers".

Wednesday, April 23

Physical Society (in the Physics Department, Imperial College of Science, Imperial Institute Road, London, S.W.7), at 5 p.m.—Discussion on "The Spark Discharge" (to be opened by Prof. Leonard B. Loeb).

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Miss Caroline Haslett: "Electricity in the Home".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. D. Gabor: "New Possibilities in Speech Transmission".

Society of Chemical Industry, Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting; Mr. T. Rundle: "Some Problems of Trade Effluent Disposal".

Tuesday, April 22—Wednesday, April 23

Institute of Physics, X-Ray Analysis Group (at the Royal Institution, 21 Albemarle Street, London, W.1).—1947 Conference.

Tuesday, April 22

"Training of X-Ray Crystallographers for Science and Industry". At 9.30 a.m.—"Requirements of Industry and Training by Industry"; at 2 p.m.—"Training of X-Ray Crystallographers in Polytechnics and Universities"; at 8 p.m.—Mr. H. P. Rooksby: "The Technique of X-Ray Powder Photography".

Wednesday, April 23

"New Techniques and Results". At 9.30 a.m.—"New Methods and Results of X-Ray Analysis"; at 2 p.m.—"New Industrial Techniques and Results".

Thursday, April 24

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. A. Todd: "Combinants of Pencils of Conics and Quadric Surfaces".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Miss J. G. Marley: "A Statistical Survey of Certain Aspects of the Beef Producing, Dairying and Cattle Rearing Industries in Great Britain between 1939 and 1945".

Institution of Electrical Engineers (at Kingsway Hall, Kingsway, London, W.C.2), at 5.30 p.m.—Prof. L. B. Loeb: "Electrical Discharge through Gases" (Thirty-eighth Kelvin Lecture).

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Dr. J. W. Drinkwater and Mr. W. G. Glendening: "The Risk of Fire and Fire Prevention Methods".

Northampton Polytechnic (at St. John Street, London, E.C.1), at 7.30 p.m.—Mr. A. J. Philpot: "Scientific Instrument Manufacture and the Nation".*

Friday, April 25

Federation of British Industries (at the Merchants Hall, George Square, Glasgow).—Scottish Regional Conference on "Research and the Progress of Industry in Scotland". At 10 a.m.—"The Established Industries"; at 5.30 p.m.—"Balancing Scotland's Industries".

Society of Public Analysts and other Analytical Chemists, Polarographic Discussion Panel of the Physical Methods Group (in the Physical Chemistry Lecture Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 3 p.m.—Dr. W. Cule Davies: "Remarks on Polarographs"; Dr. G. Jessop: "Notes on Polarographic Technique"; Dr. E. R. Roberts: "The Analysis of Brass Plating".

Chemical Society, Newcastle and Durham Section (in the Chemistry Lecture Theatre, King's College, Newcastle-upon Tyne), at 5 p.m.—Scientific Papers.

University College (at Gower Street, London, W.C.1), at 5.15 p.m.—Dr. J. F. Danielli: "Cell Physiology and Pharmacology" (other lectures on May 2, 9, 16, 23 and 30).*

Institution of Electrical Engineers (joint meeting of the Measurements and Transmission Sections, at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. W. Casson and Dr. F. H. Last: "Ultra-High-Speed Relays in the Fields of Measurement and Protection".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. S. Timoshenko: "Stress Concentration and Fatigue Failures".

Society of Chemical Industry, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 5.45 p.m.—Annual General Meeting.

University College (at Gower Street, London, W.C.1), at 5.45 p.m.—Prof. R. O. Kapp: "The Presentation of Technical Information" (other lectures on May 2, 9 and 16).*

Manchester Statistical Society, Industrial Group (at the Manchester Society of Architects, 16 St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. E. D. van Rest: "Probability and the Experimenter".

Society of Dyers and Colourists, Manchester Section (at the Gas Department Showrooms, Manchester), at 6.30 p.m.—Dr. G. L. Royer: "Studies on Rayon Dyeing—Application of the Dyeometer".

Saturday, April 26

Association of Scientific Workers, North-West Area (at Milton Hall, Deansgate, Manchester), at 2.45 p.m.—Delegate Conference on "Industrial Health".

Institution of Chemical Engineers, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 3 p.m.—Mr. J. Maddock: "Process Costing and Cost Control".

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Senior Scientific Officer in the Plant Breeding Divisio of the Ministry of Agriculture for Northern Ireland—The Assistan Secretary (Establishment), Ministry of Finance, Stormont, Belfas (April 25).

Lecturer in Physics—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants. (April 26).

Biochemist—The Secretary, Animal Diseases Research Association Moredun Institute, Gilnerton, Edinburgh 9 (April 26).

Teacher (graduate) of Mathematics, a Teacher (honours graduate) of Physics, and a Teacher (graduate) of Physics and Chemistry—The Principal, Acton Technical College, High Street, Acton London, W.3 (April 26).

Lecturer in Biology with subsidiary Chemistry, and Lecturer (2) in Chemistry—The Principal, Municipal College, Romford Road Stratford, London, E.15 (April 26).

Lecturer in Mathematics up to Higher National Certificat standard—The Principal, Handsworth Technical College, Golds Hil Road, Birmingham 21 (April 26).

Lecturer in the Electrical Engineering Department of th Croydon Polytechnic—The Education Officer, Education Office Katharine Street, Croydon (April 26).

Lecturer in Electrical Engineering—The Principal, Count Technical College, Dartford, Kent (April 26).

Graduate in Genetics, Agriculture, Veterinary Science o Physiology, for work involving abstracting and preparation of review—The Acting Director, Imperial Bureau of Animal Breeding an Genetics, King's Buildings, West Mains Road, Edinburgh 9 (April 28

Keeperships of the Departments of (*a*) Biology, (*b*) Antiquitie (*c*) Art—The Director, Museum and Art Gallery, New Walk, Leiceste endorsed with the appropriate words 'Keeper of . . .' (April 28).

Chair of Botany in the University of Tasmania—The Agen General for Tasmania, Golden Cross House, Charing Cross, London W.C.2 (April 30).

Director of Surveying—The Registrar, King's College, Newcastle-upon-Tyne (April 30).

Scientific Officer in the Blood Transfusion Service a Manchester—The Regional Blood Transfusion Officer, Royal Infirmar Manchester (April 30).

Wool Research Scholarship founded by the International Wo Secretariat—The Registrar, The University, Manchester 13 (April 30

Advisory Officer in Grassland Husbandry—The Secretar North of Scotland College of Agriculture, 41½ Union Street, Aberdee (April 30).

Lecturer in Bacteriology—The Secretary, King's College o Household and Social Science, Campden Hill Road, London, W. (April 30).

Assistant Lecturer in Botany—The Registrar, The Universit Leeds 2 (April 30).

Lecturer in Educational Psychology—The Registrar, Th University, Leeds 2 (May 1).

Tutor or Assistant Tutor in Biochemistry or Physiology—The Secretary, Somerville College, Oxford (May 1).

Assistant Physicist (full-time) in the L.C.C.'s Hospitals Service—The Medical Officer of Health (S.D.6), County Hall, London, S.E. (May 1).

Lecturer in Mathematics—The Registrar, University Colleg Singleton Park, Swansea (May 3).

Lecturer in Civil and Mechanical Engineering, and a Lecture in Workshop Processes—The Clerk to the Governors, Woolwic Polytechnic, Woolwich, London, S.E.18 (May 3).

Principal Agricultural and Horticultural Officer an Principal of the Farm Institute—The Director of Educatio Shire Hall, Nottingham (May 3).

Lecturer in Physics, a Lecturer in Chemistry (with speci qualifications in physical chemistry), an Assistant Lecturer I Mathematics (pure or applied), and an Assistant Lecturer I Chemistry—The Principal, Royal Holloway College, Englefie Green, Surrey (May 3).

Official Fellowship and Lectureship in Chemistry—Th Rector, Exeter College, Oxford (May 3).

Lecturer in Textile Testing in the Department of Texti Industries—The Registrar, The University, Leeds 2 (May 5).

Associate and Full Professorships in the Department O Physics—The Head of the Department of Physics, University British Columbia, Vancouver, B.C., Canada (May 12).

Assistant Lecturer in the Department of Geography An Anthropology, with special qualifications in Cartography—Th Registrar, University College of Wales, Aberystwyth.

Speech Therapist—The County Medical Officer, County Ha Hertford.

Senior Lecturer in Physics—The Clerk to the Governors, Wolverhampton and Staffordshire Technical College, Education Offices, Nort Street, Wolverhampton.

Assistant Lecturer in Horticulture—The Registrar, Universit College, Exeter.

Laboratory Technician (Grade B) in the Department O Physiology—The Warden and Secretary, London (Royal Fr Hospital) School of Medicine for Women, 8 Hunter Street, Londo W.C.1.

Physicist to the Radiotherapy Department—The Secretar Superintendent, Royal Sussex County Hospital, Brighton.

Chemists (men and women, temporary) in the Chemical Inspectio Department of the Ministry of Supply—The Ministry of Suppl Est. 5 (B) 2, Room 828, Adelphi, London, W.C.2, quoting Chem. 6

Technician (Grade A) for the Regional Serological Referenc Laboratory (Ministry of Health), Oxford—The Director of Patholog Radcliffe Infirmary, Oxford.

Head of the School of Pharmacy—The Clerk and Treasure Dundee Technical College, Bell Street, Dundee.

Physicist or Engineer for research into problems of lace manufacture—The Research Officer, Lace Federation Research Counci 71 Upper Parliament Street, Nottingham.

Further Education 551
Fossil Man. By Prof. W. E. Le Gros Clark, F.R.S. 553
Biology of Carcinogenesis by Chemical Compounds. By Dr. E. Boyland 554
The Late-Glacial Period. By P. Tallantire and S. M. Walters . . 556
Science in Adult Education. By Dr. M. H. Clifford 560
The International Union of Physics: Activities of the Union, 1923–39. By Prof. R. W. Ditchburn 562
Obituaries:
  Dr. Alexander Scott, F.R.S. By Sir Robert Robertson, K.B.E., F.R.S.; Dr. H. J. Plenderleith 564
  Sir Joseph Barcroft, C.B.E., F.R.S. By Prof. E. D. Adrian, O.M., F.R.S. 565
News and Views 565
Letters to the Editors:
  Neutron Experiments of the Physical Laboratory of Groningen.—Prof. D. Coster, Hl. de Vries and H. Groendijk . . . 569
  Disintegration of Nitrogen into Four α-Particles by Collision with Deuterons.—P. H. Fowler, Miss H. B. Burrows and W. J. J. Curry 569
  Elementary Photochemical Process in Halides of Bivalent Metals.—Prof. K. Butkow and Ir. Wojciechowska 570
  Oxidation Activity of Selenium Dioxide.—Prof. H. L. Riley . 571
  Location of Thunderstorm Centres from Directional Observations of Atmospherics During Sunrise and Sunset.—Dr. S. R. Khastgir, M. K. Das Gupta and D. K. Ganguli . . . 572
  An Optical Magnification for Finite Objects.—H. H. Hopkins . 573
  Electron Microscopy of Tobacco Necrosis Virus Crystals.—Dr. Roy Markham, Dr. Kenneth M. Smith, F.R.S., and Dr. Ralph W. G. Wyckoff. 574
  Alloxan Diabetes and the Kidney in the Rat.—Dr. Allen Gold . 574
  The Renal Factor in Alloxan Diabetes.—Prof. G. Lyman Duff, Donald C. Wilson and Gardner C. McMillan 575
  Practical Three-Hour and Two-Hour Cylinder-Plate Assays for Penicillin.—Dr. Robertson Pratt and Dr. Jean Dufrenoy . 576
  Nucleotide Metabolism of Bacteria and the Bacterial Nucleus.—B. Malmgren and C.-G. Hedén 577
  Cytochemical Effects of Œstradiol.—Prof. R. Jeener . . . 578
  Synthesis of Methionine and Similar Amino-Acids.—J. R. Catch, Dr. A. H. Cook, A. R. Graham and Sir Ian Heilbron, F.R.S. . 578
  Origin of Erythrocytes.—Prof. W. E. Le Gros Clark, F.R.S.; Dr. S. H. Wajda 579
  Internal Waves and Upwelling of Oceanic Water from Mid-depths on to a Continental Shelf.—L. H. N. Cooper . . 579
  Relative Directions of the Electric and Magnetic Vectors in Electromagnetic Waves *in vacuo*.—Dr. N. S. Japolsky . . 580
  Origin of Solar 'Static'.—Dr. Chas. E. R. Bruce 580
Chemistry of the Proteins 581

FURTHER EDUCATION

BOTH the significance of the further education of young people and adults in Great Britain and the magnitude of the organisational problems which are involved in the creation of a national scheme are emphasized in the Education Act, 1944. The responsibility of local education authorities is clearly defined—"to secure (i) full-time and part-time education for persons over compulsory school age; (ii) leisure-time occupation, in such organised cultural, training and recreative activities as are suited to their requirements, for any persons over compulsory school age who are able and willing to profit by the facilities provided for that purpose". It has, however, become increasingly clear that the discharge of such a responsibility by local education authorities requires more than the provision of teachers, buildings and equipment. Not only does it involve an assessment of the educational needs of the community and presuppose, as the Education Act acknowledges, a close relationship between local education authorities and many local interests; it also implies a change in the functions of these authorities and in their relationship to each other.

So long ago as February 1946, the Ministry of Education accepted the view that "the organisation of further education must be on a regional basis if all the needs of industrial and commercial personnel are to be covered adequately". Efforts have, in the past, been made to solve this difficulty in Yorkshire by the establishment of a Regional Council of Further Education, and in Lancashire, North and South Wales, and the Midlands by similar councils. This trend towards regional co-operation received a new impetus and significance when the Percy Committee on Higher Technological Education recommended that Regional Advisory Councils should be established throughout the country "on the general lines of those now in existence in some areas", and that, "as an integral part of the regional machinery, Regional Councils should create Regional Academic Boards of Technology composed of academic heads of universities and technical colleges and members of their teaching staffs".
